

Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

- + *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.
- + *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.
- + *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.
- + *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. Gehen Sie nicht davon aus, dass das Erscheinen eines Buchs in Google Buchsuche bedeutet, dass es in jeder Form und überall auf der Welt verwendet werden kann. Eine Urheberrechtsverletzung kann schwerwiegende Folgen haben.

Über Google Buchsuche

Das Ziel von Google besteht darin, die weltweiten Informationen zu organisieren und allgemein nutzbar und zugänglich zu machen. Google Buchsuche hilft Lesern dabei, die Bücher dieser Welt zu entdecken, und unterstützt Autoren und Verleger dabei, neue Zielgruppen zu erreichen. Den gesamten Buchtext können Sie im Internet unter <http://books.google.com> durchsuchen.

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

THE

PREVENTION OF CANCER

A LECTURE DELIVERED AT THE WEST LONDON POST-GRADUATE COLLEGE.

By C. B. KEETLEY, F.R.C.S.,

Senior Surgeon to the West London Hospital.

THE most able short statement of the position in which medical science stands with regard to cancer is an article in the *Times* of April 21st, 1902, entitled “The Investigation of Cancer.” The author’s final conclusion is that “we must force ourselves to wait.” These words express the opinion of what might be looked up to as medical authorities at the present date. Certainly they express the views of the *Lancet* as well as of the *Times*. However, the former journal, with its accustomed fairness, permitted me four years ago (August 31st, 1901) to advance and support a contrary view, and I wish to develop this view now more completely for the followings reasons:—

(1) A single statement never attracts due attention in these days of energetic advertisement. It is not found sufficient even in the case of a quick remedy of an eye-striking description, while my recommendation was of unexciting methods which involved taking pains, a course to most people more objectionable even than spending money.

(2) My paper was quickly followed by recommendations from other medical men, who profoundly believed each in his own panacea, recommendations of so bizarre, not to say sensational, a kind that they practically “guyed” my argument and suggestions. I refer more especially to the paper read by Dr. James Braithwaite, of Leeds, on November 11th of the same year, entitled “Excess of Salt in the Diet a probable Factor in the Causation of Cancer.”

(3) In looking over the literature of the subject since 1901, it appears to me that such authors as have paid any attention to my paper may be classified into those who have criticised it after reading my name and not reading my paper, and those who have read and made use of the paper, and a speech delivered at the West London Medico-Chirurgical Society without noticing my name at the head of them.

I hold that the time is now as ripe and as promising for the organisation of a system for the effective prevention of cancer as in 1870 it was ripe for the introduction by Lord Lister of a system for the prevention of the deadly complications of wounds in the presence of which the surgeons of those days stood nearly helpless. Nay, the times are even more ripe now, for four reasons:—(1) that Listerism has succeeded in its task; (2) that since it was introduced, mind not before, the glass makers, the optical instrument makers, and the bacteriologists, by successive improvements, which could not have been foreseen with confidence by any man in 1870, have made

possible the discovery, demonstration, and biological study of the actual causes of the deadly infections of wounds, causes which Lister could surmise only; (3) that in spite of the extensive knowledge of these causes which an army of observers have now been accumulating for a generation, the surgeon still relies for the salvation of his patients on measures for the prevention of wound infection, and when he is driven to the use of sero-therapy falls back upon anti-streptococcus serum, and even tetanus antitoxin with feelings of no great confidence. (What if we had “forced ourselves to wait” in 1870 for the bacteriological discoveries which have now, after thirty-five years placed nothing in our hands except serums which are insufficient for general purposes of cure, however wonderful may be their occasional successes under favourable circumstances!) (4) That bacteriology, while it has done so little to help us to cure wound infections, has been of the greatest assistance in helping to study the precise and the comparative value of agents useful for the prevention of such maladies.

It is therefore plain that we are in a much better position to plan a system of disease prevention now than anyone was thirty-five years ago.

Yes! it may be replied, but Pasteur had demonstrated the nature of wound infections before that time, and Lister had only to devise a workable plan based on a theory already proved. This view is absolutely incorrect, although it has been put forward by writers who ought to know better. They have evidently been misled by Lister’s conscientious not to say generous habit of making full acknowledgment of his obligations to Pasteur. Nevertheless Pasteur paved the way for Lister, and I believe it will be found that, in a similar way those investigators and Koch have prepared the way for a practical system capable of preventing cancer. Pasteur and his predecessors had demonstrated the cause of putrefaction. But the micro-organisms which cause wound infections were not demonstrated until after the introduction of Listerism.

All depends on whether or not the materies morbi of cancer is or is not some living principle introduced into the stricken animal from without. It does not matter whether this materies be vegetable, like the bacillus of tubercle, or animal like the parasite in malaria, if bacteriology has proved anything it has proved that such principles or causes of disease cannot live long in the presence of degrees of heat lower than those required to make ordinary organic and inorganic substances cease to be useful as food.

Are then the grounds for attributing cancer to some living micro-organism strong or weak? For my part, I think they are overwhelmingly strong.

In the first place, nearly ALL diseases (as distinguished from injuries such as cuts, bruises, burns and the effects of mineral and vegetable poisons) are caused by bacteria. Let the mind run over an unselected list of the ailments with which both profession and the public are familiar, e.g., nasal catarrh, sore throat, tonsillitis, toothache, enlarged glands in the neck,

² See *West Lond. Med. Jour.*, 1902, vol. vii., and *Lancet*.

bronchitis, pneumonia, pleurisy, gastric catarrh, infantile diarrhoea, marasmus, appendicitis, peritonitis, acute rheumatism, various chronic rheumatisms, dysentery, typhoid, gall-stones, whooping-cough, measles, scarlatina, so-called "bilious attacks," aches of various kinds, e.g., head-aches, stomach-aches, back-aches, aching of the limbs when accompanied by fever, and not due to mere fatigue; it is known of many of these and firmly believed of all or nearly all that they are caused by micro-organisms. For example, it is known that typhoid fever is due to the typhoid bacillus, and, although it is only recently, if at all, that the bacteriology of scarlatina has been positively demonstrated, I have not met for many years a single medical man who doubted the causation of that disease by living organisms of some sort. When we turn to those recognised constitutional diseases which present a certain parallelism to cancer, owing to the fact that they produce tumours and cause ulcerations and secondary growths, we see a group whose origin from living organisms is, if possible, more certain. The tubercle bacillus is well-known to everybody. The germs of actinomycosis, of glanders, and of leprosy are also demonstrated. There remains syphilis. The clinical evidence alone should leave no reasonable person in doubt about this being a germ-produced disease. It was this group of diseases by which, according to Sir James Paget, writing in 1887: "The conformity of cancer and cancerous diseases may be tested." After pointing out that Virchow placed the growths caused by these affections among tumours under the name of "granulomata," Paget remarked that a tuberculoma in the brain or a syphiloma in a muscle has more of the general characters of a tumour than a rodent ulcer or many cancers of the lip or tongue. Further, all are prone to special modes of degeneration and of ulceration. Those which break down the centre of a cancerous gland are sometimes so like those commonly found in tuberculous glands that no ordinary operative or clinical experience can distinguish them with confidence until a report has been obtained from a good pathologist. Whatever doubt may exist in some minds about the possibility of transmitting cancer from one person to another, there can be no question but that cancer is as infectious as tubercle, "by the invasion of adjacent parts or by the transmission of material." Further there are all degrees of malignancy alike in cancer, in tubercle, and in syphilis, if we use the term malignant in an old-fashioned sense. For example, a small superficial epithelioma cured by the X-rays would not be regarded as malignant at all if we were ignorant of the terrible capacity for destruction so frequently shown in other cases anatomically similar. And what can be more remorseless than the course of some syphilitic tumours?

The difficulty of distinguishing between syphilis and cancer is so common that it has to be faced every day.

No wonder, then, that, soon after Koch's discovery of the tubercle-bacillus, there commenced an earnest search for the micro-organism of cancer, and that an army of brilliant young men have thrown themselves into it with zeal and devotion—with what measure of success it is not in my power to say. I think an excellent case has been made out for the presence of minute bodies, either microzoa or bacteria, in cancer cells, and, remembering what such appearances mean in the histology of other diseases, I should have supposed that this was an observation of great weight and probable significance. But, encouraged by the failure of workers to fulfil all the conditions which Koch laid down as required for absolute proof of an organism being the cause of a disease, a school of critics has arisen who treat such observations with scant respect, a school which appears to have received considerable encouragement from the observations of Farmer, Walker, and Moore to the effect that nuclei of cancer cells sometimes divide and behave like those of germ cells.

But these observations cannot exclude the possibility of a bacterial origin of carcinoma, for they leave the peculiar incidence of primary carcinoma in the

matter of place, and even of time, unexplained, while clinical facts, as I shall endeavour to show, are most strongly suggestive that living organisms introduced into the body from without, are the cause of cancer.

With regard to Professor Johannes Orth's dictum that "There is no necessity to assume a parasitic etiology in carcinoma," (a) this attitude on the part of pathology which has been struggling with might and main to find a parasite, is not unlike that of the inquisitive little girl who, being denied a secret she has striven to obtain, says, "Pooh, I don't need to hear it." Of course, only a great histologist can judge how pathological histology looks to her intimates, but to me, looking at her from a respectful distance, she seems to cut rather a sorry figure as regards the etiology of cancer, unless some of her votaries have really discovered a causative micro-organism.

The difficulty of proving to demonstration specific instances of infection is great even in acute diseases. Think of the eternal disputes between able observers as to the precise origin of typhoid epidemics. The furthest that is got in investigating them is usually no better than probability. With all the enormous opportunities for study in South Africa, it is still unsettled what was the relative share of water as compared with that of flies. If the typhoid bacillus were not as well known now as the Nelson column, quite a number of eminent medical men would be blaming smells, or, at least, emanations. The gentlemen who tore up all the drains every time a case of diphtheria or typhoid occurred, felt "no necessity to assume a parasitic etiology" of either. But with a slowly progressive, chronic malady like cancer, which on first commencing and for months afterwards cannot be recognised clinically, and is often not even seen during the first half-year of its existence by the doctor, it is very much more difficult to discover an immediate cause which can be proved.

Moreover, it cannot be denied that though cancer auto-infects with difficulty, otherwise early operations for cancer would not be so successful, it is terribly certain that it does auto-infect. If that were not true, late operations would not be such failures as they often are.

The same difficulties are found in tracing the precise source of the infection in most cases of tuberculosis, and for the same reason. And so it is even with actinomycosis. And thus it is that one case in which a strong presumption of infection is discovered outweighs a hundred cases in which nothing of the kind can be traced.

Before going further, let me deprecate the use of the term "pre-cancerous" as applied to some imaginary stage in which a sore or a tumour is assumed to be neither innocent nor malignant. It seems to me to complicate the difficulty we have in finding one boundary line by adding to it the further difficulty of looking for a second boundary line which has no existence. We need no such phrase to remind us that cancer is prone to attack old ulcerations, warts, and perhaps scars.

In considering what can be done to prevent cancer, let us bear in mind certain significant facts in connection with it. Most, if not all of them, I pointed out in the *Lancet* nearly four years ago. Some are well known, and will, I think, be denied by none.

1. All, or nearly all, carcinomata appear on the surface of the body, or of one of its cavities which communicate with the surface by some external orifice. A very large proportion attack the alimentary canal, many the face, head, hands, and legs, in fact, the parts which are least protected by clothes. If the clothed parts of the person were to be mapped out in square-inch areas, those particular square inches of the male body which are most frequently exposed for brief periods, namely the surface of the genitals, and, in the case of the female the breast, are the most frequent areas to be attacked with cancer.

They are also the parts most frequently handled.

(a) "Annals of Surgery," Vol. XL., p. 781.

Now surely these facts point to the origin of cancer in something introduced from without. It further supports the hypothesis of a cancer germ; for what influence introduced from without could possibly produce the phenomena of cancer with its power of auto-infection and of indefinite growth except a living organism.

Further, to quote from my own article in the *Lancet* of August 31st, 1901, vol. 2, pp. 584-586:—

“The commonest seats of primary carcinoma in the alimentary canal are obviously parts where food may lodge or adhere, e.g., the lips, the margins and under-surface of the tongue, the tonsils, the gullet behind the larynx, and again where it is crossed by a bronchus, the lesser curvature of the stomach near to the pylorus, the pylorus itself, the ileo-cæcal region, the sigmoid flexure, the rectum, any part of the alimentary canal which has been the seat of chronic ulceration or of cicatricial contraction, and the lower portion of the large bowel in those curious cases of multiple polypi which tend to delay the passage of solid fæces, just as hillocks and trees check the downward course of snow on a hillside. All these facts seem to me to point to the probability of the cancer-germ being conveyed by food, but requiring time and rest to establish itself, while taking advantage of ulcerated and otherwise injured spots.

There are, it must be acknowledged, primary carcinomata arising in places which one would scarcely think of as accessible to food, e.g., the laryngeal, the pancreatic, the hepatic, and above all the numerous uterine cancers. However, the larynx, the lungs, the pancreatic duct, and the bile ducts open directly or indirectly into the alimentary canal, and the uterus opens by way of a wide canal to the surface of the body. And it is obviously possible that primary cancerous infection may be conveyed *via* the blood-vessels or the lymphatics, just as secondary is, no tumour forming at the seat of entry, and that it then rests and multiplies at some epithelium-lined cavity which it may reach, perishing in situations where there is no epithelium. Sir James Paget's view was that all primary growths were blood diseases, but the great success of early operations seems rather opposed to this. A secondary carcinoma arising in parts normally without epithelium implies that not only the cancer-germ, but the epithelium in which it lives and the growth of which it so greatly excites, has been conveyed from one part of the body to another. This assumes, as is customary, that all cells which resemble epithelium under the microscope are certainly epithelial in origin. But this is not absolutely certain. The microscope, assisted by modern methods, is a marvellous instrument, but the structure of things seen by it is in part made out by the imagination of the observer. Hence curious mistakes occur. For example, a primary cancer was pronounced by a first-class pathologist to be sarcoma, a secondary growth in the bones, of which the patient died a year afterwards, was declared by an equally good pathologist to be carcinoma.

While it is easy to explain the infection of a part of the alimentary tract by food, it is not easy to explain the infection of the mammary gland, unless it is through the blood. But the milk-ducts are obviously possible, indeed probable, channels for the conveyance of germs from the nipple to deeper parts. It seems to me that a not unlikely manner in which the nipple, or some eczematous spot on it, is infected is by the sufferer's fingers. It is true that the fingers are seldom dipped into food, and that only those of the lower classes often handle such things as cheese. Butter, however, comes frequently into contact with the fingers of nearly all women, and it is not considered sufficiently polluting to require that the hands shall be carefully washed afterwards. When considering the possibility of water being the cancer-carrying medium, I thought perhaps the nipple was infected by the linen, but linen and cotton undergo a treatment at the laundry calculated to kill any disease essence. Flannel, however, is treated more gently; still, even flannel, though not exposed to heat, is freely rubbed with soap.

With regard to the frequent occurrence of cancer on the hands of workers in petroleum, on the scrotum of the chimney-sweep, the lip of the pipe-smoker, and in the lungs of the cobalt-miner, it is not very likely that the cancer or any other living organism would flourish in paraffin, in carbon, in smoke, or in ore which is a mixture of a metal with sulphur and arsenic. Such substances probably merely pre-dispose to cancer by preparing the soil, sometimes by causing a chronic eczema, a wart, or an ulcer.

The usual belief seems to be that non-operative treatment and the tissues of the body are powerless in the presence of cancer. The clinical evidence seems to me to point to a difference in degree rather than in kind between innocent and malignant tumours in this respect.

1. Malignant tumours sometimes retrograde and occasionally even disappear. This is most frequently noticed when the sufferer is being subjected to some special form of treatment, and consequently is being watched with special care.

2. Cancer does not loiter and live in the lymphatics on its way between a primary cancer and the nearest glands. Dr. Snow suggests that the cancer cause is destroyed by the lymph. (*West Lond. Med. Journ.*, Vol. VII., p. 117.)

3. With regard to treatment, cancer, especially when young and small, is sometimes seen to retrogress, at least temporarily, under the influence of the same measures as those often used successfully for the cure of tubercle, namely, iodide of potassium, X-rays, and even change to healthier and brighter surroundings. At least, the last-mentioned influence seems to delay recurrence. (D'Arcy Power.)

4. In my experience, Thiersh's skin grafts have appeared to possess a similar influence in preventing return after excision in the case of superficial cancers, to that which they have when the lesion is tubercle.

“If my remarks should lead anyone to avoid uncooked food, and if also it should prove in the end that articles of diet have nothing to do with the conveyance of cancer, let it be remembered that the danger of contracting other diseases, such as tubercle, typhoid, dysentery, diarrhoea, trichiniasis, tape-worm, and hydatids is already sufficient to justify such an attitude towards unsterilised foods. It is an attitude which a proper national system of instruction in hygiene should teach every school child to assume.

“The following rules for the prophylaxis of cancer might, therefore, be laid down safely, because even if they did not gain the end immediately desired they would attain others scarcely less valuable, just as the sons in the fable, though with all their digging they found no buried gold in the field bequeathed to them, yet gained health and rich crops.

1. Chronic inflammations, suppurations, and especially ulcerations, should not be neglected or allowed to drift. Still better, commencing troubles of the kind should be treated promptly and not allowed to become chronic. With regard to ulcerations, especially of the alimentary canal, and with regard also to suppurations, especially of the breast, it is to be remembered that even the cicatrices left by their cure are said to be liable to become the seat of malignant infection. It is therefore doubly desirable to cure such ulcerations and suppurations in their earliest stage, so that little or no cicatricial tissue may remain, and in cases where the arguments for and against the removal, as opposed to the simple healing of an ulcer, are otherwise evenly balanced, the indication to remove a place especially liable to cancer, should prompt one to excision.

2. Well-known sources of irritation of mucous membranes and of skin should be avoided—e.g., smoking when any trace of soreness is discovered in the mouth, on the tongue, or on the lips, and the habitual use of strong condiments and spices. Workers in special trades, such as chimney-sweeping, should lose no time in having cutaneous rashes, warts and sores, promptly cured. Among milk products, cheese itself is an irritant to mucous membranes. Some syphilitics with a tendency to ulceration of the tongue

notice that a fresh attack frequently follows eating cheese.

" 3. A woman should allow nothing to come in contact with her nipples except smooth, clean linen, cotton, or silk, and the soap and warm water with which she washes herself. After being washed the nipples should be gently and thoroughly dried. She should not touch them with unwashed hands or fingers at all. During lactation, the nipple should be cleaned and gently dried after each act of suckling, and then protected with a dry and clean covering. The nipple should not be merely withdrawn from the infant's mouth and pushed back under the mother's clothes. If wool be worn it should be sterilised by heat.

" 4. Whoever takes unsterilised food should recognise that he does so at the risk of introducing into his system the germs of disease, and that among these disease essences, so to call them, may be that of carcinoma.

I have used the word "sterilised" because so few foods can be relied upon to be sterile unless they are artificially made so. But there are foods which may be reasonably trusted, even when raw, if prepared with care and cleanliness. For example, fruits and vegetables protected by rinds or shells, if perfectly fresh and sound, but not if in part decayed or blighted, also, perhaps, meats if examined by a careful and skilled person with a practical knowledge of animal pathology; although I do not know how the services of such an one could be available for any except the wealthy or the seriously ill, or in public institutions. The necessity of caution in these matters is shown by the fact that bacteria can occasionally be found in new-laid eggs.

Some of the vegetables and fruits which would be spoilt for the palate by being cooked should be carefully cleansed and in the case of tubers, quickly scalded superficially. Could anything be more careless or futile than the toilet to which grapes and strawberries are usually subjected? Think of the circumstances amid which both are grown, gathered, and packed for the market.

With regard to the process of sterilising food, it is not merely a question of cookery, it is also one of cleanliness on the part of all persons directly or indirectly associated with the preparation and serving of the food and of those who cleanse the utensils.

It is the demand for this which will be found most difficult to supply. The radically imperfect ideas of what is true cleanliness still existing among all classes may be seen any day in any hairdresser's shop, however fashionable.

The principal points to bear in mind are that nothing can be properly cleaned unless plenty of time, soap and warm water, as well as some elbow-grease are used, and that merely dipping dishes into a tub in which the other kind of grease is combined with dirty water is not sufficient even when followed up with a wipe from a dirty cloth; but it is surprising and unfortunate that an excellent mimicry of cleanliness can be and is obtained in this way. Similarly the dirty coat-cuff which the barber while shaving rubbed on fifty noses yesterday leaves no mark on the fifty noses it may rub to-day, or at least none that will appear until it is too late to trace its origin, but it is none the less dangerous.

Is it then impossible to get a household into habits of true cleanliness? The daily experience of the best surgical hospitals shows that fair success can be obtained with unpromising materials. The first requirement is that the mistress should be truly clean herself. The second that her house should have a good hot water supply, and that she should not be parsimonious in soap, soda, towels, and cloths; the third that she should establish a proper system of washing, one in which basins shall be large, water shall be changed sufficiently, time and energy not grudged, and clean cloths supplied and used for wiping.

Another point is raised by what has gone just before. What if the poor cook herself is suffering from cancer?

Three years ago (February 27th, 1902) Sir Alfred Cooper read an excellent paper on Inoperable Cancer, and in the debate on it I spoke as follows:—(*West London Medical Journal*, vol. vii.; also in brief notice in the *Lancet*):—"There is one aspect of the treatment of inoperable cancer to which I think attention is called practically never, and that is the protection of other people from the unfortunate sufferers from cancer. Everyone who accepts, as I suppose nearly all of us do, the hypothesis that cancer is probably due to some germ or other, either animal or vegetable, surely must realise that each case of advanced cancer, especially every case attended by discharge, must be a possible focus for spreading the disease among people who have hitherto been fortunate enough to escape. I do not think any of us give sufficient heed to that aspect of the question. I noticed in one of the medical journals the opinion expressed that cancer was spread by snails. I do not think the observer thought snails went about biting people who had cancer. But at all events it shows how readily we are to go altogether out of the way to find some causation for a disease when we have right before our eyes, constantly calling attention to itself, such a possible cause of the spread of cancer as the existence of these advanced inoperable cases, especially those of the throat and mouth which cause a discharge; as well as cases of ulceration of the breast (and other concealed parts) in unfortunate people who, even if educated, seem not to realise that their discharges may be mischievous to others." In the private consulting room, no less than in the hospital out-patient department, it is common to find patients with chronic ulcerations, and those who nurse them, so contemptuous of discharges, the sight of which would nauseate persons less familiarised, that they seem to go out of their way to put fingers and thumb especially the thumb, into the middle of each polluted dressing after removing it. And many are perfectly careless how and where they place the removed dressing.

They have generally behaved in this way for months or years and seen no harm come of it. But, as Huxley says, "Nature makes not the smallest allowance for ignorance," and the day of retribution comes eventually, but, alas! in such a manner that it brings with it no readable lesson, and usually weighs more heavily on the innocent than on the guilty. Guilt is, of course, scarcely the word for lapses of whose danger the doers are absolutely unconscious.

We get diseases from one another, we give our diseases to one another, in childhood for the most part directly, in adult life oftener indirectly. (Hence the danger to health of crowded communities, of large schools, and of great cities.)

Safety lies in cleanliness, in the destruction of excreta and discharges, and in the avoidance of needless personal, physical intimacies. These truths make not only for health and long life, but also for morality and purity.

To sum up, for the prevention of cancer, we should look to—

- (1) The sterilisation of food, including clean cookery and clean service.
- (2) The destruction of discharges from ulcerations, especially if cancerous.
- (3) The prompt excision of cancerous tumours or ulcers. Early removal of a cancer performed in a correct and thorough manner, not only gives the patient an excellent prospect of complete cure, but also removes a possible focus from which other people may become cancerous.
- (4) The avoidance of physical familiarity except with those who are nearest and dearest to us.
- (5) Abstinence from alcohol, tobacco, and from foods which leave waste products of which the kidneys, bowels and skin cannot easily and thoroughly get rid, and which thereby provoke and sustain the chronic

inflammations and ulcerations which so often pave the way for cancer. (a)

These rules tend not only to the prevention of cancer, but to the general preservation of health, and even to the promotion of morality.

THE QUINIC ACID TREATMENT IN GOUT AND URIC ACID DIATHESIS.

By J. WEISS, M.D.,
Basle, Switzerland.

In the year 1899 I suggested, on the strength of some physiological experiments I had made, that the employment of quinic acid in gout and uric acid diathesis in general should receive wider consideration. Since then numerous treatises for and against my theory have made their appearance, and many preparations been put on the market for which it was claimed that they possessed the power to relieve suffering humanity owing to their composition of quinic acid and some other previously known "gout" remedy (piperazine, urea, urotropine, &c., &c.). It should on the whole be superfluous to contradict so absurd a theory as that lithia, piperazine, and other bases are drugs inclined to in the least influence uric acid diathesis; but it is in medicine that obsolete ideas of this nature are not easily rooted out. Berthollet's dictum was that: "In a solution of acid and bases each acid is divided on to all the bases present according to the measure in which each base is present." Thus, the greater part of the urea must combine with the sodium which is present in large quantities; most of the lithia with the likewise preponderating hydrochloric acid. Despite these facts, lithia and piperazine continue to be used and no doubt improvement will be observed in a case occasionally—*post hoc, ergo propter hoc*.

Apart from the influence of a remedy on uric acid secretion, every consideration is due to the question whether this very point is really of such vital importance. It is not rare that uric acid secretion in the urine undergoes a change during an attack of gout, and, after all, we have before us only a symptom of a disorder whose origin lies in the nervous system. It is, more especially in France, a favoured method to attack the complaints in its place of origin by means of colchicum; but in view of the evil effects of this drug on the heart, I leave such treatment alone. Although the composition of the urine is unimportant for the determination of the gouty process as such, it will show us whether a drug has wrought any change in the organism. If, for instance, we observe a decrease in the uric acid secretion after administering quinic acid, and a simultaneous ample secretion of hippuric acid; if, further, we see that uric acid deposits in various parts of the body diminish, that the patient's general condition improves, we may conclude that the remedy administered has an influence on uric acid formation and secretion in the whole organism, acting either on the synthetic formation of uric acid or on the trophic nervous system. It has been alleged that quinic acid could only have an effect (if effect there were at all) in that benzoic acid, separating from the quinic acid, combines with glycochol, thus forming the more soluble hippuric acid. An exceptionally smart firm offers, under the name of Urol, a combination of quinic acid and urea; according to the theory explained above the effect of one component, of course, cancels that of the other! Now, the greater portion of the uric acid in the human organism is not formed synthetically (as in birds and reptiles) but by oxydation. This, however can be no reason for us to abandon a remedy whose beneficial action is clearly proved. With no remedy can we trace an effect from

reaction to reaction; neither with quinine in malaria, nor mercury in syphilis—to say nothing of serums.

As to observations, I should first of all mention that the task of determining quantities of uric and hippuric acid demands great skill and accuracy on the part of the investigator, as well as conscientiousness and reliability on the part of his "object." I consider it an impossibility to take as reliable the results obtained by some youthful experimentalists during a fortnight or even a month; for I have myself found with several hundreds of experiments that accuracy increases with the number of observations. It is frequently a question of very small quantities, where every milligramme is of importance as influencing the percentages. Then there are many processes which easily entail losses, and finally there is the necessity to obtain the urine as soon as possible after its release from the bladder; if 24 hours old it is useless, giving as it does, and as I have proved in my experiments, inaccurate results. Investigation as to quantity is of value only with a constant diet, under other conditions of diet it is useless to devote any time to the question of quantity. It really goes without saying that the composition of the urine is influenced by the nourishment received, but I mention it in consideration of various treatises which I have before me, and which have no claim whatever to any scientific value. With our clinical investigations the case is different, and by these the success of the quinic acid therapy has been undeniably established. It has been proved sufficiently, and beyond doubt, that quinic acid produces no undesirable secondary effects. I have personally taken doses up to 50 grammes, and have given similar doses to persons suffering from arterio-sclerosis and valvular disorders without ever noticing untoward effects. In its pure state it is unpleasant in taste and detrimental to the teeth, obliging us to use a salt. As the cheapest and most rational form I give the preference to urosine, the quinate of lithia—the lithia, as previously stated, always considered as a mere diuretic.

In view of the many utterances for and against quinic acid treatment (mostly based on one, sometimes two trials) I have recently subjected six persons to close observation, two of the number being arthritic patients. Whilst five showed a distinct decrease in uric acid secretion, this was not the case with the sixth, nor was there a noteworthy increase of uric acid secretion; with this patient the secretion was fairly ample also under normal conditions.

Experiment 1.—A. M., labourer, æt. 32, never been ill, apart from infantile complaints, and an attack of pneumonia when 16 years old.

Diet:—400 grammes meat, 200 g. bread, 50 g. butter, 90 g. sugar, 3 g. common salt, ½ litre water, 1 litre beer.

	Quantity of urine.	Uric acid per day.	Hippuric acid per day.
2nd day	1400 g.	1.2634 g.	not ascertainabl
3rd "	1459 g.	1.3186 g.	" "
4th "	1436 g.	0.9453 40 g. ac. quin.	0.8974 g.
5th "	1475 g.	0.6372 g.	0.9326 g.
6th "	1428 g.	0.9834 g.	0.2134 g.
2nd day	1422 g.	1.3024 g.	not ascertainable.
3rd "	1438 g.	1.2864 g.	" "
4th "	1502 g.	1.0325 g. 30 tabs. uros. (15 g. lith quin)	0.6345 g.
5th "	1530 g.	0.8038 g.	0.7039 g.
6th "	1420 g.	1.1934 g.	0.1540 g.

Experiment 2.—T. E., labourer, æt. 45, never been ill, except with infantile complaints and gonorrhœa (when 20), the urine still showing threads at times. Same Diet as No. 1.

	Quantity of urine.	Uric acid per day.	Hippuric acid per day.
2nd day	1589 g.	0.8432 g.	not ascertainable.
3rd "	1536 g.	0.9046 g.	" "

(*) This included rule forbids that excess of meat-eating, &c., to which the late Sir Mitchell Banks, Dr. Haig, and others have not unreasonably given a place in the etiology of cancer.

Quantity of urine.	Uric acid per day.	Hippuric acid per day.
4th day 1578 g.	0.6845 g. 40 g. ac. quin.	0.7345 g.
5th " 1530 g.	0.3536 g.	0.9042 g.
6th " 1564 g.	0.5279 g.	0.1035 g.
2nd day 1578 g.	0.8734 g.	not ascertainable.
3rd " 1563 g.	0.8523 g.	" "
4th " 1625 g.	0.7524 g. 30 tabs. uros.	0.6234 g.
5th " 1705 g.	0.5368 g.	0.8043 g.
6th " 1608 g.	0.6734 g.	0.0978 g.

I conducted these two experiments in two parts at eight days interval, the first with pure quinic acid, the second with urosine. Both gave the expected results. In the following experiments I employed only urosine tablets à 7½ grains lith. quin. Diet same as in Experiments 1 and 2.

Experiment 3.—E. K., book-keeper, suffers from pulm. emphysema.

Urine.	Uric acid per day.	Hippuric acid per day.
2nd day 1480 g.	0.9123 g.	not ascertainable.
3rd " 1538 g.	0.9546 g.	" "
4th " 1620 g.	0.6734 g. 30 tabs.	0.5203 g.
5th " 1705 g.	0.4258 g.	0.7840 g.
6th " 1605 g.	0.7034 g.	0.2036 g.

Experiment 4.—S. B., commercial man, æt. 54, arthritis urica since 35th year, showing itself in periodical swellings of one or both phalangeal joints every 1—3rd year. Father said to have had gout.

Urine.	Uric acid per day.	Hippuric acid per day.
2nd day 1506 g.	0.8734 g.	0.0432 g.
3rd " 1532 g.	0.8234 g.	0.0487 g.
4th " 1605 g.	0.7964 g. 30 tabs.	0.4326 g.
5th " 1628 g.	0.5034 g.	0.4873 g.
6th " 1593 g.	0.6845 g.	0.0985 g.

Experiment 5.—L. M., commercial man, æt. 47, arthritis urica since 42nd year. Four attacks in five years.

Urine.	Uric acid per day.	Hippuric acid per day.
2nd day 1623 g.	1.2456 g.	0.0056 g.
3rd " 1642 g.	1.1978 g.	0.0052 g.
4th " 1648 g.	1.0365 g. 30 tabs.	0.1135 g.
5th " 1705 g.	0.7536 g.	0.4263 g.
6th " 1613 g.	0.9645 g.	0.2305 g.

Experiment 6.—R. B., clerk, æt. 30, no illness except infantile complaints recorded.

Urine.	Uric acid per day.	Hippuric acid per day.
2nd day 1532 g.	1.2056 g.	0.8756 g.
3rd " 1551 g.	1.2134 g.	0.8943 g.
4th " 1526 g.	1.0024 g. 30 tabs.	0.9046 g.
5th " 1684 g.	0.9586 g.	0.8927 g.
6th " 1606 g.	1.0345 g.	0.9034 g.

This last case was all the more interesting as Hupfer (in a by-the-way very poor treatise) describes similar results from the treatment of his own case, and considers himself justified to thereupon condemn the quinic acid therapy from a scientific point of view.

In order to establish clinically whether arthritis urica is influenced through quinic acid, *i.e.*, urosine, I experimented on a number of people, some of whom suffered from chronic, others from periodically, at fairly equal intervals, recurring attacks of arthritis urica.

Case 1.—A. T., late officer in the army, æt. 58, obese, gouty deposits in several finger joints. Numerous gouty attacks since 43rd year, consisting in painful swelling of the big toe. He took, in 1900, at the commencement of one of these attacks, 10 urosine tablets (equal to 5 grm. with quin.), whereupon swelling and pain decreased considerably. The same dose was again administered after one week and then modified to eight and six tablets daily in the course of a month. In the following spring the patient without experiencing his old complaint, took six tablets for one month;

likewise in the year 1902. During all this time there were no attacks, whilst patient had had to face at least two attacks annually previous to treatment.

Case 2.—E. R., butcher, æt. 45, had, in 1808, a typical gout attack in right metatarso-phalangeal joint, which recurred every year, lasting from seven to fourteen days. In May, 1900, patient began taking six tablets urosine daily for one month, and has repeated this every year since. There have been no further attacks. In the summer of 1901 he felt a slight pain in the affected joint, whereupon he took ten tablets daily for a week, with the result that the pain disappeared completely.

Case 3.—P. S., commercial man, æt. 50, for ten years troubled with arthritis urica. Numerous tophi in finger joints, gout attack lasting from fourteen to forty days every summer. In the year 1901 he commenced an urosine treatment, taking ten tablets daily, as soon as pains in the right big toe appeared. After a fortnight of this treatment he was at least no longer quite incapable of moving about. In a further fortnight the disturbing symptoms had ceased; nevertheless, the dose of ten tablets daily was maintained for another fortnight, then decreased to eight tablets during fourteen days, and subsequently to six during a like period. In the following spring he took ten tablets daily for a fortnight, eight daily during the next, and six during a third period of fourteen days. There was no attack, and there has been none since, as patient has repeated the treatment every year.

I have mentioned a few typical cases; similar ones have been observed by others. I have found that a month's urosine treatment in the spring (10, 8, and 6 tablets, as in Case 3) is able to suppress those troublesome gout attacks generally experienced in the summer, without producing untoward secondary effects. Such food as consists wholly or partly of pancreas, &c., should be avoided; otherwise restrictions are unnecessary. The tablets are best taken dissolved in water, at meals.

I am able, on the strength of my experience, to recommend the urosine treatment, and here repeat what I said at the Medical Congress at Wiesbaden in 1900: "In urosine, the quinate of lithia, we possess a remedy which, in the treatment of uric acid diathesis, ranks as high as the salts of salicylic acid in articular rheumatism and the quinine salts in malaria."

THE TREATMENT OF INSANITY BY THE ADMINISTRATION OF SHEEP'S THYROID SUBSTANCE.

By RICHARD R. LEEPER, F.R.C.S.I.

Medical Superintendent, St. Patrick's Hospital, Dublin.

ONE finds that the administration of the ordinary drugs used in the treatment of physical illnesses gives very vague and often completely negative

results when exhibited in the medical treatment of the insane.

Sedatives excepted, the good results obtained by drugs administered solely for the purpose of favourably influencing its psychical disturbances associated with mental diseases have proved wanting. Even in such a sharply defined disease as locomotor ataxy and the general paralysis of the insane, where a specific cause is definitely ascertainable, the drug treatment ordinarily indicated, and used in syphilitic disease is found to give no definite results; indeed, the early inunctions of mercury and the administrations of iodide of potash would appear from my own experience to actually accelerate the downward course of those suffering from a specifically caused degeneration of the cortex or cord.

Patients sent to mental hospitals for their treatment are complex puzzles, as the symptoms of disease must ever puzzle us when unexplained by a clear conception of normal function; and when treatment is based upon a vague, nebulous, and often a merely scientifically imaginative pathology, treatment must necessarily at present be empirical or open to some experimental possibilities when pathology leaves us so far unenlightened. Brain symptoms we presume are due in some cases to hæmic or intestinally absorbed toxins, inflammatory conditions, or bacteriological organisms or exudates around the nervous centres derived from one or all of the disordered blood, lymphatic or glandular symptoms. One must necessarily be at a loss to select a remedy which will favourably influence a disease the etiology of which is so confusing, and often merely conjectural, and the pathological chemistry of its varied forms must, as yet, be regarded as inseparably connected in uncertainty with the present state of our knowledge as regards the physiological chemistry and changes of tissue associated with normal and healthy life.

The clinical picture of stupor, mania, or melancholia is clear enough. Would that we could as clearly recognise the pathological conditions which underlie these states, then doubtless many remedial courses which are at present lying at our hands would be ordinarily employed, but which now lie neglected owing to want of knowledge as to their uses and applicability. Small are the crumbs and fragments of definite knowledge which are available to guide us in our search for a sound and more precise therapeutical means of grappling with the problems of psychiatry.

It appears to me that the treatment of insanity must be based upon the principle of broadest conception, so that treatment must be directed to so altering metabolic processes as to stimulate into increased vitality and functional life the various organs temporarily aberrated by the onset of insanity; or producing that disease by their primary disturbances. We must look, therefore, to general systemic remedies if we wish to influence or markedly alter the course of the mass of symptoms, mental and physical, which we are called upon to treat. We must treat the patient as a whole, not confining our drug exhibitions to the alleviation of symptoms produced as we may conjecture by altered blood pressure, anæmia, or a cerebral intoxication produced by the absorbed auto-intoxications of degenerating nervous tissue, or that carried from other sources within the

body, and producing the phenomena of mental disease.

Surgery has been disappointing in its results, and the trephining of the skull, as a remedial remedy for mental conditions, unassociated with traumatism, or localised disease, is in the present state of our knowledge an unwarrantable proceeding.

Viewing the treatment of insanity from these standpoints of present-day knowledge, I some years ago sought in organotherapy, a remedy potent and physiological, and with the then known results of the exhibition of gland substances, I commenced to use the sheep's thyroid gland as a means of favourably affecting or modifying the condition of the insane. My first case was one of chronic mania associated with ill-defined myxœdematous symptoms. This case rapidly improved, and left the hospital completely recovered.

I then and subsequently used the sheep's gland in tabloid form in cases of stupor, mania, and melancholia.

I have in all treated twenty-two patients with thyroid extract administered in the form of 5 gr. tabloids manufactured by Burroughs and Wellcome. The dose is gradually increased from 10 grs. daily to as much as 60 grs. in some severe and otherwise intractable cases, and continued until reaction occurs. In all cases the patients have been confined to bed during treatment, and have been most carefully nursed and constant observation of pulse and temperature recorded. The treatment has been discontinued when a noticeable rise of temperature or increased pulse rate has been produced. In no case have I had any accident or reason to suspect that the patient was unfavourably influenced by the treatment. In one case which I considered from the first a rather unfavourable one for treatment, a severe gastric crisis seemed to have resulted from the administration of the substance. This was the case of a girl with a neurotic inheritance who was partially demented and suffered from a large goitre.

The treatment entirely removed the large goitre, but failed to produce any change in the mental state.

Of twenty-two cases treated, suffering from various forms of mental trouble, seven were males and fifteen females.

Three of the men completely recovered, and two of these three patients were homicidal to a marked degree.

I have treated three patients in all, suffering from homicidal impulses with thyroid extract. In all of these three cases a marked change took place subsequent to the thyroid treatment, and the morbid impulses seemed to be lost. I cannot say if this observation may be regarded as anything more than a coincidence, but I commend it to the consideration of those who have a better opportunity of further investigating the results of thyroid treatment with this difficult class of patient. It is interesting to note that it has been suggested by Lugaro to partially extirpate the thyroid in cases of moral insanity; an excessive secretion of thyroid being regarded as the cause of excessive amativeness, thieving and other mental warps of degeneracy.

Should the exhibition of sheep's thyroid prove favourable in cases suffering from homicidal impulses, it may be conjectured that the human

secretion and that of herbivorous animals may act in different ways and affect mental states in different degrees. The carnivora seem rather more affected by extirpation of the thyroid than herbivorous animals, and much good work in the direction of ascertaining the comparative amount of iodo-thyroid found in the secretions of different animals and a comparative analysis of the secretion in herbivorous and carnivorous animals is much needed so as to allow of the selection of that secretion most potent medicinally.

Of the twenty-two patients treated by me with sheep's thyroid, twelve recovered and were discharged from the hospital, and have not since, so far as I can ascertain, been treated with one exception elsewhere or required re-admission here.

Some of the cases had been for some years insane, and had been transferred here from other asylums and were regarded as incurable by their relatives.

My experience of the clinical symptoms produced by the administration of thyroid substance coincides generally with that observed by Bruce. It seems to act primarily by increasing the cardiac action and pulse rate, with lowered blood pressure. In but two or three cases did a rise of temperature first appear as a reaction to the treatment, and even after the use of the substance in large doses for some weeks, the temperature never rose beyond 102°. I have in all cases ceased to administer the substance upon the advent of pulse or temperature reaction.

All of my cases lost weight rapidly whilst under treatment, but more than regained (often by some stone), this loss upon the cessation of the gland tabloids, thus indicating that the ultimate cellular metabolism of their bodies was stimulated by the effect of thyroid feeding. From my observations of the effect of thyroid I believe it to be imperative upon us to give otherwise ill-doing cases the benefit of a course of treatment by this means. I believe it to exercise a marked and noticeable effect upon the ideational and intellectual faculties.

The result obtained in one of the cases otherwise unfavourably affected by the treatment was most noticeable.

A. B. was a young married woman possessed of a very insane family history. She was always a neurotic and rather eccentric woman. She married a drunken and dissipated husband, who robbed her and deserted her, leaving her with three small children. Her insanity dated from this period, and upon her admission she was apparently semi-demented, incoherent, and stuporose. Could not at times be induced to speak or take any interest in her surroundings.

She was given large doses of thyroid and the substance was increased until she was taking 30 grs. a day, when a decided rise of temperature and increased pulse-rate occurred.

She became more rational, but exhibited great anxiety, and would ask me, "Don't let him kill me," "Don't let him hurt the children," which she had never before asked about or taken any interest in.

Evidently the mental distress had been recalled, and the state of anxiety restored which immediately preceded, and was the undoubted exciting cause of her attack of insanity.

With the cessation of the thyroid feeding and the physical symptoms produced thereby the

anxiety disappeared, and the patient has again relapsed into her demented state.

Suicidal impulses have been recalled as result of thyroid feeding in persons who were suicidal and had become partially demented; and this was noticeable in one of my cases who had attempted suicide by cutting her throat before admission here. She eventually completely recovered, and was discharged some years ago, and has since remained well.

Thus morbid as well as normal mentalisation can be stimulated by this extraordinary gland secretion. I have no experience to warrant my drawing conclusions as regards the value of organotherapy by the secretions and substances of other organs, such as the suprarenal, &c. I was much gratified to find that the distinguished neurologist's (Dr. Marie) experience of thyroid coincides with my own. He told me he derived no good results from the administration of other gland substances. It occurs to me that the administration of parathyroid substance (if a trustworthy preparation of this portion of the thyroid area is obtainable) would be likely to give marked results in connection with the nervous system.

In the cases of dementia præcox, or adolescent insanity with insane family histories, treated by thyroid by me, I have had some strange results. In two young men so treated they appeared to apparently recover, became rational, bright, and sensible for short periods, and again relapsed and are still insane.

These cases would appear to suffer from a congenital brain instability which breaks down at the developmental period of adolescence, can be forced into an apparently normal condition for a brief period as the result of the stimulative action produced by thyroid feeding.

I have treated these cases by a second course of the substance, but with no appreciable result, the nerve recuperative power being exhausted; and incapable of re-stimulation into normal activity.

In the sheep's thyroid we undoubtedly possess a substance capable in selected cases of modifying most and curing many forms of mental disease. Whether the administration of herbivorously derived thyroid supplies some want in the deficient or diseased human secretion, or whether mere excess of iodothyroid or other substance of the gland, no matter where derived, is of benefit to insane states remains for future investigators to decide.

The Out-Patient Departments.

THE ROYAL BERKSHIRE HOSPITAL.

Cases under the care of R. PHILIP BROOKS, F.R.C.S.,
Ophthalmic Surgeon to the Hospital.

CASE I.—*Congenital Aniridia of both Eyes with Stellar Cataracts.*—Ellen L., æt. 19, has always had bad sight.

Examination.—Both corneæ clear, but no iris visible in either eye until light is focussed obliquely into the angle of the anterior chamber, when a narrow band of iris tissue is seen.

By direct examination with the mirror of the ophthalmoscope a large star-shaped opacity can be seen near the posterior capsule of the lens. The peripheral portion of the lens is quite clear. Its margin can be well seen and beyond this a narrow space representing the suspensory ligament, but no ciliary processes are visible.

By indirect examination with the ophthalmoscope the optic discs can be fairly seen and appear normal.

The condition of both eyes is similar, the cataract being rather larger in the left.

Vision.—R. eye=3-60 and with sph. $3.5D=6-24$. L. eye=3-60 and with sph. $+3D=6-36$. With the above glasses the patient could read J₂ of the small type fairly well, and these glasses were therefore ordered for constant use. There was no history of any similar condition in the family.

CASE. II—Hypopyon Ulcer with Lachrymal Obstruction.—Ann J., æt. 54, complained that the right eye had been bad for three weeks.

Examination.—The centre of the cornea is occupied by a deep infiltrated ulcer covering the whole of the pupil. The iris appears dull and sluggish, and the lower segment of the anterior chamber is filled with a hypopyon. There is marked ciliary infection and much conjunctival discharge. The edges of the lids are reddened, the lower lid being excoriated and somewhat everted. Pressure over the position of the lachrymal sac causes a regurgitation of muco-pus from the lower punctum.

Treatment.—After several instillations of cocaine and the conjunctival sac having been washed out with a solution of hydrarg. binioidide (1-10,000) the point of a Weber's knife was entered through the lower punctum and the canaliculus divided. Couper's probes Nos. 3 and 5 were passed through the nasal duct.

The lids were then kept apart by a speculum and the eyeball held by fixation forceps, while the galvanocautery was applied to the edges and floor of the ulcer. Atropine ointment was then applied and the eye dressed with a boric acid fomentation and a light pressure bandage.

Remarks.—The frequent association of hypopyon ulcer with lachrymal obstruction is of great importance in treatment. The absence of regurgitation on pressure over the lachrymal sac does not disprove obstruction. Therefore, whenever the hypopyon relapses after treatment, the nasal duct should be probed or at least syringed through to demonstrate its patency, otherwise our best efforts may be thwarted by a continuous re-infection of the ulcer from the lachrymal passages.

Transactions of Societies.

THERAPEUTICAL SOCIETY.

SIR LAUDER BRUNTON, Bart., M.D., F.R.C.P., in the Chair.

At the last meeting of this society, Dr. G. Herschell read a paper on the APPLICATION OF DRUGS TO THE INTERIOR OF THE STOMACH BY MEANS OF SPRAYS OR NEBULÆ.

He said that this mode of administering drugs was useful, as it gave a certainty of the drug reaching the affected part, though only a small quantity of a strong solution was used, and thus prevented any poisonous effect. One half-ounce of spray would cover the interior of the stomach as effectually as 10 oz. of a solution. The spray is used either to disinfect the stomach, to act as an astringent or styptic, or thirdly to relieve the pain of cancerous or other ulcers. It is very useful in erosions, chronic gastric catarrh, and hyper-secretion. The best apparatus is Einhorn's, made only by Tierman of New York, consisting of a spray producer and a long soft rubber tube. The solutions used are silver nitrate 1 in 500 or in 1,000, 1 in 1,250 of cocaine, 1 in 1,000 of either hydrochloric acid or of adrenalin.

The drug must be administered when the stomach is quite empty, and has been washed out and the water removed by an aspirator. Thus the distance from the teeth to the stomach is ascertained, and marked on the soft tube by a ring of rubber, the warm tube is then passed down the œsophagus to this point, and the spraying commenced by pressing the ball for three or four minutes, while the tube is gradually pushed on for 3 centimetres.

Silver nitrate is especially useful in erosions, also

in chronic gastritis, and in hyperchloridic acid secretion. In gastralgia cocaine gives great relief immediately, even in small quantity. In hæmorrhage adrenalin in spray stops the bleeding, but the tube must not be passed more than one inch into the stomach.

Nebulæ are atomised oily or viscid liquids finer than spray, by being broken up against the walls of the instrument, by forcing the liquid by a pump or bellows through a globe nebuliser and down a double soft rubber tube into the stomach. The double tube prevents over-distension. The nebuliser is then removed, and all the vapour allowed to escape. The usual solution employed consists of oil of cinnamon ʒdr., menthol ʒdr., and paroline ʒoz. Cinnamon oil is one of the most powerful disinfectants, and menthol is used for its soothing qualities. This process is chiefly used for thoroughly disinfecting the stomach in cases of motor insufficiency which cannot be accomplished by drugs give by the mouth.

Dr. Bryant not being able to attend the meeting, Dr. Herbert French read the paper on

ALGINOID IRON

for him. It is claimed for this drug that it has two advantages over other compounds of iron; first, it does not derange digestion; second, it does not cause constipation. Alginic acid is a nitrogenous acid obtained from seaweeds, which forms an insoluble salt with iron, by decomposing ferric chloride with sodium alginate. It is a brown tasteless powder not changed by acids, or the gastric juice, but decomposed by alkalis. It contains 10 per cent of iron. It is best given in powder or cachets, dose 2 to 15 grains. It is particularly useful in cases of chlorosis with vomiting and pain in the stomach, as it acts as a sedative instead of irritating it, checking the vomiting and not causing constipation. It may be conjoined with arsenious acid. It is especially useful in anæmia arising from the hæmatemesis of gastric ulcer, as its sedative action relieves the pain, and checks the vomiting, and the general aspect of the patient improves, and the hæmoglobin of the blood is increased. In one case of chlorosis the hæmoglobin increased from 40 per cent. to 72 per cents. in six weeks, after taking 10 grains of alginate of iron three times a day.

The advantages of this preparation are;—

1. It is tasteless but contains 10.97 per cent. of iron.
2. It has no astringent effect and does not cause constipation, but is slightly laxative.
3. It is not changed in the stomach, and may be given even during vomiting, as, like salts of bismuth, it acts as a sedative.
4. It is readily borne by patients who can take no other form of iron.

CENTRAL MIDWIVES BOARD.

MEETING HELD JUNE 29TH.

DR. CHAMPNEYS, President, in the Chair.

A LETTER was read by the secretary from the Committee of the Queen Victoria Jubilee Institute for Nurses, protesting against the recent decision of the Board to hold four examinations in the year instead of three, and asking the Board to reconsider its decision.

As several letters of this kind had been received, it was agreed to hold a conference on the subject on June 29th, and to invite the various bodies to come or send delegates.

The vexed question of fees to medical men called in in times of difficulty and danger, and who should pay those fees, was then discussed. The doctors of South-end had unanimously arranged not to take less than two guineas, but the fact would certainly deter people from calling in a midwife if, along with her 12s. 6d. there was a possibility of another two guineas to be paid. Dr. A. W. Aldrich, of Leyton, in a letter (quoted) complained that he had been offered half a guinea when called in in an emergency by the midwife.

It was agreed to return answer that no fee had been fixed by the Board, Miss Paget adding that 10s. 6d.

was a large sum to come out of the nurse's own pocket.

With regard to the examination in October, Dr. Robert Boxall and Dr. Alexander Stokes were appointed as two examiners, and Dr. G. E. Herman and Sir William Sinclair as visitors.

MALPRAXIS.

Dr. Le Fort, a well-known specialist in urinary affections and particularly in the treatment of stricture by electrolysis, in which he has been particularly successful, came to grief in two cases some time ago, and for which he had to appear before the police court last week. The first case was that of stricture of the cesophagus. While passing the electric bougie, a considerable portion became detached and lodged in the stomach. As the patient was too weak to attempt gastrostomy, nothing was said about it, and finally the man succumbed to the primary affection. This accident was not imputed to the surgeon, however, by the prosecution. The other case was stricture of the urethra, and from some fault in the instrument, as in the first case, several inches became detached and entered the bladder. For some strange reason the operator concealed the accident not only from the patient, but also from his relatives, and several months afterwards the patient succumbed to chronic cystitis. Nothing probably would have been known about either case, were it not that Dr. Le Fort had for some reason dismissed his secretary, who, in order to be avenged of what he considered an undue treatment by his employer, retaliated by disclosing the secrets.

The defendant brought forward several of the best medical authorities to testify that, after all, the foreign bodies did not accelerate death, and which the court allowed; but they blamed him for concealing the accidents, and imposed a penalty of two pounds.

A QUESTION OF SURVIVANCE.

An enterprising confrere in search of notoriety attended the execution of a criminal last week, and arranged with the executioner that as soon as the head fell into the basket he (the doctor) would take it in his hands and shout into the ear the name of the murderer to see if he would respond by some sign. The experiment was gone through as stated and the doctor affirms that the head opened its eyes twice when his name was pronounced. Very little credence is given to the doctor's story, and in any case such experiments are of very little scientific value.

The above reminds us of a similar experiment tried in the days of the Empire—we mean that of the celebrated La Pommerais. La Pommerais was a doctor practising in Paris, and for some reason or other became a criminal. He insured the life of a woman to whom he was attached and then poisoned her. He was tried and condemned to the guillotine. The night before his execution he was visited by a friend and confrere who asked him in the interest of science if he would open his eyes if he heard his name called out after decapitation. He promised to do so, but when his confrere held the head in his hands and called him by name there was no response. The eyes remained closed.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, July 1st, 1905.

At the meeting of the Medical Society the discussion on

CEREBRO-SPINAL MENINGITIS

(called for some reason in the English papers "spotted fever") was continued.

Hr. A. Baginsky said he had had no increase of tuberculous meningitis lately in his department. It was always rather more frequent in the earlier part of the year, and became less frequent later on. The differential diagnosis between tuberculosis and sporadic

meningitis was not so difficult in general. In the acute form the disease began more suddenly. The sensorium was deeply affected only in the very acute cases in those running a slower course, it was always free to some extent, whilst in tuberculous meningitis the sensorium was early attacked and at the most lucid moments were observed. In tuberculous meningitis the temperature was only moderately high, but very high in the other form. The stiffness of the neck in the sporadic form even when it was slow in its progress was much more pronounced through the whole illness than in the tuberculous disease. In the latter disease the spinal fluid was clear, and most delicate flocculi were deposited on standing, in the sporadic disease it was clouded—an *obiter media* might under some circumstances cause a mistake in diagnosis. There was also an influenza form that could only be distinguished from cerebro-spinal meningitis with difficulty. He saw a case which even the autopsy did not render clear. He had only found the meningococcus in small numbers. As regarded treatment, we had to confess our helplessness in regard to it.

Hr. Henke laid stress on the fact of the difficulty of deciding even *post mortem* as to the nature of the disease, whether it was the epidemic form or not. He had previously found both the meningococcus and the pneumococcus. He had produced meningitis experimentally with both. For a decision on the question, the absence of any primary disease such as otitis, pneumonia, or angina was of importance.

Hr. Friedberg described a case of hydrocephalus that was punctured and recurred repeatedly. The child never had fever, but diplococci were found in the fluid removed. These were cultivated by Wassermann and declared by him to be Jäger-Weichselbaum meningococci.

Hr. Grawitz also spoke of the difficulty of early diagnosis when it was most important. Meningitis was not a disease of childhood, by preference it attacked people in early manhood, especially soldiers.

Hr. Westenhoeffer said that the most important result of his investigations was that infection did not take place through the cribriform-bone, but through the posterior wall of the fauces. Angina had often been noticed among those living in Silesia.

Hr. Kirchner said that in Upper Silesia 2,406 cases had been reported; with 1,491 deaths. The death rate, 63 per cent., had now become higher, as many of the cases running a chronic course had since died.

To combat the disease effectively it was necessary to report even suspicious cases, and not to wait until the diagnosis was clear in every case. Adults had only a slight receptivity as regarded the disease, but it could be heightened by certain injurious conditions such as military service.

At the Surgical Congress Hr. Friedheim reported on the permanent results of operation for Basedow's or Graves' Disease. Twenty cases were operated on. Operation was the only known means of permanently curing the disease, and the dangers of it were not great. All the cases operated on were bad ones. One patient died of tuberculosis four years after the operation, fourteen were permanently cured, five of them had needed no medical aid for from nine and a half to eleven years. Three were described as much improved. One death was to be deplored; it occurred in the case of a girl at. 23, for whom first the right, and six weeks later the left, struma was removed, so that only a small isthmus remained. Tetanus came on and proved fatal on the tenth day. The first successful treatment by operation was reported in 1884. The report was received with doubt as the goitre was everywhere looked upon as only an individual symptom of the disease. Now it was known that the hypersecretion of the thyroid was in casual relationship to the disease, and many surgeons in consequence of this had carried out the operation. In order to avoid serious consequences, only a part of the gland should be removed, but as to how much should be taken away, there was no agreement in opinions, as no one knew how great a quantity of poison there must be to lead up to the disease.

Many surgeons operated tentatively, removing only comparatively small portions of the gland at each of several successive operations. Perhaps in this way a later operation might lead to a cure in the three cases reported as much improved.

Rehn had made a collective investigation as to results, and this gave 50 per cent. of complete successes, with a mortality of 20·1 per cent. The speaker's own material gave 70 per cent. of cures and a mortality of 5 per cent., and Kocher, Krönlein *v.* Mikulicz and König had had equally good results.

Hr. Kocher of Berne could fully confirm the statement made. The result of surgical procedure gave the proof as to the nature of the disease. He said that the best results were obtained in the recent cases. Fatalities should be debited to late operations.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, July 1st, 1905.

VAGINAL ATROPHY.

At the Gesellschaft der Aerzte, Peham exhibited a patient, *æt.* 40, with partial obliteration of the genitals. The woman had never menstruated, nor been troubled with *molimina* menstrualia. The *mammæ* were well developed, *mons veneris* normal amount of hair, *labium*, *clitoris* and *nymphæ* fully developed. The site of the vagina is covered by an irregular fold of the hymen which guides the finger into the urethra and thence easily into the bladder, through which she has had sexual intercourse since her marriage twenty years ago. From her own description *libido* and sexual sensation in *coitus* appears to have been normal. From this enormous distension of the urethra incontinence of urine caused her to seek medical advice last year. The ordinary remedies failing, an examination revealed the above abnormal condition.

The internal organs of generation could not be exactly described in the present condition, but external examination revealed a small firm body on each side, about the size of a mussel, which were assumed to be ovaries.

PSEUDO-ARTHROSIS.

Lorenz made another attack on Moseitig for his ill-advised criticism of Lorenz's treatment of *coxitis* and the production of *pseudo-arthritis* after the operation. As a proof of what he believed, Lorenz brought forward fifteen cases where *ankylosis* had occurred after operations, and which he had treated without surgical interference, and produced functional movement. He further showed a series of cases of *coxitis* at present under treatment in whom he also hoped to obtain *pseudo-articular* movement. He admitted that operative treatment was an *ultima ratio*, and that extensions and bed fixtures as well as portable extensions and fixation *apparati* should all be banished from the mind as iniquitous agents in the treatment of joint diseases, producing irreparable atrophy of the affected limbs. He characterised them as the worst of crutches concealed beneath the clothes. During the last ten years he had practised functional and physiological methods in the conservative treatment of joints and never used extension and fixation as usually practised. Practice had taught him that the fixation of the hip-joint is relatively easy and painless, requiring a very short time for the functional and physiological treatment. Moseitig in reply, recounted the various indications, course, and symptoms of *coxitis*. At the beginning of the treatment he admitted that it was more of an expectant orthopædic hygienic nature than of heroic form, but when pus formed *arthro-oncotomy* was a necessity in all severe conditions. Where spontaneous luxation and extra capsular abscesses formed associated with fever and other complications, he considered resection unavoidable; even in some cases where the abscesses produced *fistulæ* in the healing process resection was also indicated. Eiselberg thought that this wordy warfare was based upon fallacious premises, as Moseitig was reasoning from the worst of cases, while Lorenz was forming his method of treatment on mild ones.

CONGENITAL SYPHILIS.

Hochsinger showed a man, *æt.* 21, whose history pointed to congenital syphilis. When a child he seems to have been treated for the disease, and at a late period suffered from hepatic and cerebral symptoms of the disease. During the exhibition of these para- and meta-syphilitic affections he suffered from *paroxysma hæmoglobinuria* which would occur when he was five years of age. When eleven he suffered from ocular paralysis and other cerebral symptoms. At thirteen *enuresis*, aortic trouble, and *neurasthenia* set in; at seventeen *infantilismus* and the first symptoms of the present condition *tabes dorsalis* were observed with changes in the joints of the little fingers. The Röntgen rays confirmed the infantile anomaly of want of union between the bones and epiphysis of the phalanges. The present state shows that the bones are unchanged with a great thickening of the synovial membrane. This *synovitis chronica hypertrophicans* is also present in the joints of the small bones. Teley asked if the mother of this young man had been treated for syphilis which he considered important in the transmission of syphilis to children, as he felt some scepticism in many of these cases. Hochsinger in reply, feared that he could not give him such information, neither could he elicit any proof that would confirm the presence of such a disease in the mother.

Operating Theatres.

ROYAL FREE HOSPITAL.

OPERATION FOR ACUTE INTESTINAL OBSTRUCTION DUE TO VOLVULUS OF THE SMALL INTESTINE.—Mr. WILLMOTT EVANS operated on a woman, *æt.* 26, who had been admitted for acute abdominal pain and vomiting of thirty-six hours' duration. Two years previously, she had been operated on at another hospital for an ovarian cyst. There was a well-marked history of gastric ulcer with *hæmatemesis*. The day before admission she woke up with intense abdominal pain, vomiting soon commenced, and recurred every few minutes; she was unable to keep down any food. The constipation had been present for two days. The pain and sickness steadily grew worse, and on the evening of the next day she was brought to the hospital. On examination the abdomen was distended, painful, and tender, and hardly moved at all on respiration. The scar of the former operation was seen in the middle line below the umbilicus. The patient was much collapsed. It was obvious that an acute intestinal obstruction was present, and it was decided to operate at once. As it was considered that the obstruction might be due to adhesions in connection with the former operation, the abdomen was opened not through the scar but about half an inch to the left of the middle line. When the peritoneum was divided, collapsed bowel was seen, and on examination with the hand it was found that distended small intestine was adherent to nearly the whole length of the scar. On tracing the distended bowel downwards, it was found that about two inches below the adherent bowel the small intestine was bent sharply on itself, the bowel immediately below being collapsed. The adherent intestine was dissected carefully from the abdominal wall, and as soon as this was done the previously collapsed bowel became distended. Five stitches were placed in the wall of the bowel where the adhesions had been so as to leave no portion of the bowel wall uncovered by peritoneum. The wound and the neighbouring portion of the abdominal cavity were irrigated with normal saline at a temperature of 103°, the wound was then sewn up in layers, and a gauze and collodion dressing applied. Mr. Evans said that in this case the diagnosis of acute intestinal obstruction

was obvious, the constipation, vomiting, abdominal pain, and distension being well marked. Nothing could be done by palpation, therefore a diagnosis of the cause of the obstruction was impossible, but inasmuch as the patient had had a previous abdominal section, and as adhesions after abdominal section are by no means rare, it seemed not unlikely that there was some causal connection between the previous operation and the obstruction. As to the treatment, there was no room for doubt. No one dreams nowadays, Mr. Evans pointed out, in such a case of doing anything but an abdominal section, though only a few years since a distinguished surgeon advised inversion and shaking under an anæsthetic of such cases. Mr. Evans further remarked that it would have been noticed that he had left a large quantity of saline solution in the abdominal cavity with a temperature several degrees above the normal. The object of doing this was twofold: In the first place, to obviate shock, for this warm fluid would be quickly absorbed and would tend to make up in part for the large amount of fluid lost by vomiting in the two days during which the patient had been able to keep nothing down; there was, however, a further advantage in leaving this fluid in the abdominal cavity; he considered it tended to prevent the formation of adhesion, of the harmfulness of which this case was a striking example. It was obvious, he said, that nothing but an abdominal section could have saved this woman's life, and twenty-four hours' delay might easily have rendered the operation of no avail. Sealing the wound with gauze and collodion was in his opinion decidedly the best method of dressing operation wounds where no drainage was needed, as it minimises the amount of dressing required and permits the wound to be seen without any risk of infection which might occur during re-dressing.

The subsequent history of the case was uneventful. For a day or two the patient had a little abdominal pain, and she was troubled with slight bronchitis from which she had suffered for some time before operation. She left the hospital three weeks after operation wearing an abdominal belt.

THE General Council of the Seine has decided to pension off at an early date the senior (*doyen*) *pharmacien en chef* of the lunatic asylums. The vacancy thus created will not be filled, and the event betokens an impending reform in the pharmaceutical department of the hospitals, a reform which will in various ways effect a considerable aggregate saving.

THE annual meeting and dinner of the Brussels Medical Graduates' Association will be held on Thursday, July 13th, at 7 p.m., at the new Gaiety Restaurant, under the presidency of Dr. F. R. Miller. Members desirous of attending are requested to notify the Honorary Secretary, Dr. Edwards, Camberwell House, London, S.E.

An official intimation has been issued that the fifth meeting of the International Congress of Obstetrics and Gynæcology, to have been held at St. Petersburg in September next, has been postponed for a year.

DURING the week ending June 17th there were 19 cases of typhoid fever notified in Bridgend, and in the previous week there were 13, making a total of 65 cases since the beginning of the outbreak in the third week of May.

An anonymous donation of £500 has been sent to the Bristol Royal Infirmary.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 5, 1905.

INEFFICIENCY OF THE CENTRAL MIDWIVES BOARD.

THE machinery of the Central Midwives Board having now been for some time fairly in action, it may be well to inquire whether its methods and achievements are of a satisfactory nature. Its policy and administration have so important a bearing upon the interests of the medical profession that it becomes imperative for the editors of medical journals to keep a close eye upon the proceedings of the Board. It has been our duty from time to time to criticise and at times to impeach the body in question from the day of its inception up to its most recent meeting. We regret to record our opinion that the Central Midwives Board as at present conducted, is an unbusinesslike body run upon lines that must sooner or later bring disaster to midwives and to the medical profession, as well as discredit to those responsible for its official organisation and control. These statements may appear strong, but we feel that matters have come to such a pass that the only chance of getting back to safe and open country lies in the clear and full recognition of the facts of the case. The composition of the committee presents a curious mixture of strength and weakness. The lay members so far as we can see appear to wield a ridiculously disproportionate power in the deliberations of the Board. The fact that they were able to insist upon the supervision of qualified medical examiners by laymen is alone sufficient to stamp the proceedings of the Board as "ill-advised, arbitrary, and to the utmost degree subversive of the reasonable rights and claims of the medical profession." The midwives first prayed humbly to be recognised as a class of lay helpers working under the supervision of properly trained and qualified medical men. Now backed by legislative mandate they claim with an arrogance that rises to sublimity a place superior

to the profession, and they have actually established their foothold within the hitherto sacred walls of the medical examination room. It seems almost impossible that a resolution so degrading to the dignity of the medical profession could have been passed under the presidency of a medical man. We regret to record our opinion, however, that not only in the particular matter mentioned, but in many others Dr. Champneys appears to have supported every possible interest except that of his own profession. In him we had hoped to find a President with the requisite strength and tact to discharge the duties of an admittedly delicate post with justice to all concerned. Unless his methods undergo a rapid and complete revision we fear that there will soon be no straw of hope left for our former anticipations to cling to. Time after time those strong and able medical representatives, Sir William Sinclair and Mr. Ward Cousins, have left the Board-room full of angry protest against the way in which important matters were shelved and not infrequently settled in their absence by a "catch" vote. The meetings of the Board are far too few in face of the enormous mass of business that has to be conducted. Instead of close and orderly debate upon points involving important principles the time of the Board is consumed for the most part in wrangling over minor points. The standing Committee business consumes the greater part of the limited time of the meeting. When the routine business of the Board is reached it is time for the country members to catch their trains. Again and again have they raised their voices in emphatic protest against the methods of the Committee as administered by Dr. Champneys. It seems to us that the medical profession should take this matter up seriously and insist that a full and impartial hearing be given to their representatives. To give a specific instance of the unbusinesslike conduct of the Board: the question of fees payable to medical men called in by midwives in times of stress and danger is clearly of crucial importance. The Board meeting held on Thursday last spent several hours over Committee and had scant time to discuss this subject. They declined to fix a fee, and Miss Paget, a lay member of the Board, said that half-a-guinea offered in one instance by a midwife to a medical man was a large sum to come out of a nurse's pocket. Why does not the Board speak out on the matter, and say who ought to pay the fees, and what amount should be paid? In Southend the medical men have determined to charge two guineas whenever called on by a midwife. Equally scant consideration was given to complaints from midwives on the subject of examinations, the number of which had been fixed at previous meetings of the Board with scant attendance and after perfunctory discussion. It would be well for Sir William Sinclair and Mr. Ward Cousins forthwith to give their version to the medical profession in the shape of an informal report.

THE DISCOVERER OF THE CIRCULATION OF THE BLOOD.

FOR so many generations Englishmen have stood firm and solid in the belief that William Harvey was the discoverer of the circulation of the blood, that it is to the average man almost as great a heresy to suggest that Harvey had predecessors as it is to the student of literature to suggest that Shakespeare was not really the author of the plays attributed to him. Nevertheless, there are many patriotic and well-informed people in different parts of the world who are strong in support of other claimants to the honour. It is said that cities contended for the honour of having given birth to Homer, and so countries have contended for the honour of having produced the discoverer of the circulation of the blood. In England three monuments have been raised to the memory of Harvey. In the Anthropological Museum at Madrid stands a monument to Servetus, the Spanish claimant. In Italy the piety of their compatriots has similarly honoured two claimants—Carlo Ruini by a monument at Bologna, and Cæsalpinus, by similar memorials at Pisa and Rome. To Colombo of Cremona others have credited the discovery with no little show of reason. Laying aside all prejudice in the discussion of what is after all a question of historic fact, there is little doubt that all those mentioned and many others—notably Aquapendente and Sarpi—contributed solid blocks to the building on which Harvey placed the coping-stone. The evidence has been very thoroughly re-examined, and summarised by Professor Hemmeter of Baltimore in a recent contribution to the *Johns Hopkins Hospital Bulletin* (May, 1905). From a study of Harvey's own works indeed it is clear that he was aware that previous to his own teaching there was knowledge of the circulation of the blood. He freely uses his right as a man of science of building on the knowledge of others, as when he quotes the observations of Colombo that the blood in passing from the right to the left heart does not traverse the septum, but is carried a long circuit through the lungs. He tells too, that he got his first suggestion of the circulation from Aquapendente whose pupil he was at Padua for some years. He mentions in a letter to a friend that Sarpi in 1623, five years prior to the publication of his own work, put in writing his proof of the uninterrupted return of blood to the heart. It would appear, indeed, that after Galen the first great step toward the discovery of the circulation was made by Servetus, who, in 1553, published in his work *Christianismi Restitutio*, for which he was burnt at the stake by Calvin, a description of the pulmonary circulation. Colombo's observations, quoted by Harvey, were independent of, though contemporary with, those of Servetus. In 1571 Cæsalpinus published a description of the circulation of the blood, both pulmonary and systemic, and twenty years later he gave the experimental proof of his theory. What then was left for Harvey?

There is no doubt that it is to Harvey we owe the complete picture of the circulation. He put together, he unified, he made reasonable and clear, he completed as a system, what had previously been merely the obscure studies of secluded students. He, in fact, proved with marvellous method and cogency, adding illuminating reflections, what, without him would have been lost as haphazard remarks whose importance had never been recognised. The harvest, as Tollin says, was ripe for the cutting, but it was necessary to find a Harvey as reaper.

PATENT MEDICINE SUPERVISION.

THE unrestricted sale of patent medicines in this country is one of the most glaring scandals that ever cried out for removal. The trade is far from being one of the decaying industries of which so much was heard a year or so ago; it is perhaps the most flourishing, and certainly the most profitable, of the day. A patent medicine that does not find enough dolts to pay for its advertisements must have been very badly put on the market, and a patent medicine that does not show a few hundreds per cent. profit on its sales must have been badly chosen for exploitation. In fact, it is an open secret that the expense attached to pushing a patent medicine is not the cost of material or manufacture, but that of advertising. The sums that are paid to bring the knowledge of the virtue of these preparations continually under people's noses are enormous, and without them the trashy stuff that provides the "literary" matter of the cheap magazine would not be available for the delectation of the man in the street, or the servant girl in the kitchen. The removal of the paper duties, which included the tax on advertisements, enabled the penny and even the half-penny paper to pay its way, but it incidentally gave rein to the patent medicine business, and the patent medicine business now constitutes a cardinal factor in the newspaper proprietor's calculations. Most of the better papers have ceased to accept these advertisements, which, under an ingenious veil, advocate immorality and crime, but we doubt if there are any which refuse advertisements because they are packed with palpable lies, or because they obviously aim at deception. The inquest that ended at Stoke Newington on June 26th, after two adjournments, should prove a warning to those whose eyes it may have happened to catch, and if among them are to be found any newspaper proprietors who admit wholesale advertisements of secret remedies, so much the better will it be. At that inquest the cause of death of two little girls, aged two and three years respectively, was enquired into. They were sisters, and had both died soon after taking, at the administration of their parents, doses of a preparation called "Liquozone," a free sample of which had been obtained by the father. Additional suspicion had been aroused as to the culpability of this preparation by the fact that both

the parents had taken some of it, and felt unwell afterwards. Liquozone is a patent medicine which has been largely advertised of late, with rather more than the usual allurements to purchasers, the British Liquozone Company offering free sample bottles to those who wish to try it. The advertisements state that £100,000 is being spent in providing a million of these sample bottles, and announcing the "offer," and it seems not unlikely that some such sum is actually being devoted to its sale, knowing as one does the capital that is often sunk in such enterprises. Liquozone is said to have been the subject of scientific and chemical research for twenty years, and to have been tested through physicians and hospitals for five. It is said not to be made by compounding drugs, nor with alcohol, but to derive its virtues from a gas—largely oxygen gas. Curiously enough, this gas is said not only to be a germicide of such potency that the proprietors will give £250 for a disease germ that it will not kill, but also to be "food for the nerves and blood." A gas that is a "food" in either the scientific or legal sense is unknown to us, and we therefore must continue to regard "Liquozone," on its own showing, as a drug. Yet in its advertisements we find it stated that "any drug that kills germs is a poison, and it cannot be taken internally." Therefore it would appear that Liquozone carries the refutation of its own claims on its face. The diseases amenable to the charms of Liquozone are given in columns, and vary from dandruff to dropsy, from bronchitis to piles, and from varicella to women's diseases. Sufferers, "in justice to themselves," are begged to try Liquozone. At the inquest, it came out that the principal ingredient of the preparation appeared to be sulphurous acid, which Sir Thomas Stevenson stated was only one-nineteenth of the strength of the British Pharmacopœial preparation. He also agreed that the pamphlet of the Liquozone Company could be described without much exaggeration as "nothing but lies." As to the actual cause of death, there was some conflict of opinion, as the *post-mortem* evidence was not very definite, but the jury eventually found that the children died of exhaustion, following vomiting and diarrhoea set up by taking Liquozone, and added that "some representation should be made to the proper authorities to have better supervision of patent medicines." Sulphurous acid, as Sir Thomas Stevenson remarked, is not much given at the present day; it is not pleasant to take, and many other drugs can be given that produce similar therapeutical effects without its corresponding disadvantages. It is not, however, a drug that is looked upon as dangerous in itself, and if it produces serious symptoms in small doses the suspicion arises that it may contain sulphuric acid as an impurity. Whether this was so or not in the case under notice, we are unable to say from the report before us; but the finding of the jury in their rider constitutes a sufficiently grave indictment of the patent medicine trade as at present conducted.

Notes on Current Topics.

The Chicago Drainage Canal.

OUR readers will remember that a few years ago the city of Chicago spent some twelve millions sterling in constructing a huge drainage canal to conduct the sewage of the city to the Des Plaines River, and thence to the waters of the Mississippi. Previous to that time sewage had been discharged direct into Lake Michigan, causing pollution of the Chicago drinking water. The intention in building the canal was that a constant flow of lake water should be maintained so as to sweep all sewage into the waters of the Mississippi. In this plan Chicago showed complete disregard for the interests of the many cities lower down that stream, all of which drew their water from it. As a result there is at the present time a gigantic lawsuit pending between St. Louis and Chicago, the former city claiming damages for the pollution of its water-supply. The method was obviously wasteful in the highest degree, but one would have thought that sufficient care would have been taken that as far as Chicago itself would be concerned it would be efficient. Unfortunately this is not the case, for after some unusually heavy rain this spring, the canal, instead of flowing in the direction expected, altered its current and for some days discharged into Lake Michigan. The result is that the water supply of the city has been seriously contaminated, as an enormous amount of solid matter must have been deposited on the lake bottom close to the supply intakes. We understand that it is found impossible to prevent a recurrence of this event, and that the use of the canal for its original purpose will have to be abandoned. It is said, however, that it may be possible to convert it into a navigable waterway between the Lakes and the Mississippi, thereby to some extent recouping the city for its enormous outlay.

Gradual Electrocutation.

A PAINFUL case, but one of considerable medico-legal importance, was the subject of an inquest at Lambeth on June 20th. An electrical engineer was putting in some extra wires in the basement of a South London house, where an installation of electric light had lately been inserted, and did not return to his fellow-workman at the time when he was expected. The latter went down to remind him that he was late, and saw the unfortunate man drop dead before his eyes. The engineer, when first observed, was found to be holding one of the wires between a pair of pliers, and there is no doubt that he must have been doing so for some time previously. Through neglect of the usual precautions, the current from the main had not been turned off during the supplementary operations, and part of a live wire was seized with the pliers. The ground on which the engineer stood was damp, and instead of the current running to earth it must have continued to pass into his body. A condition of tetanus appears to have been set up, so that the unfor-

fortunate victim was, although alive and aware of his danger, unable to release his hold. The current was one of average voltage, namely 220, which in the usual way would not have brought about a fatal result, and would not in this case had it not been for its continued action for some space of time. A Home Office inspector who gave evidence said that it had been ascertained by experiment that 96 was the maximum voltage up to which it was possible to go with certainty of being able to release the grip, but another witness from his own experience put it at a much higher figure. The danger is one that must continually be present in electric-lighting work, and it is difficult to conceive of a more painful and lingering death than one caused by such means.

Consumption and Hair.

THERE has arisen a prophet in New England who has made public the cause and cure of consumption of the lungs. The cause is the clipping of the locks on the head of man, and the cure the letting them grow. Nothing could be simpler, and nothing could be, according to the prophet in question, Mr. Edward Beckham, by name, more logically established. Having himself contracted tubercle of the lungs, he entered a hospital for consumption in Philadelphia, and while there he noticed a failure of the hair crop in his fellow patients. The riddle was solved. He thereupon let his hair and beard grow, adopted an open air life, cured his disease, and, with true altruism, proceeded to preach the truth to others. Mr. Beckham's argument being however so far of an impeachably empirical nature, it was necessary to establish its rational ground. To him this presented no difficulty. "Hair," he says "supplies the ether which is the nutriment and energiser of the entire brain and nervous system. Man is simply an inverted plant. Hair is to man what roots are to a plant." Could anything more be required? Only a frivolous caviller would suggest that if the hair is producing ether it might be better to preserve it from atmospheric influence, as ethers are likely to be weakened, by aerial dilution. By such reasoning it would be easy to prove that Mr. Beckham should encase himself—or at least his hair—in case of steel against the attacks of an insidious atmosphere.

Country Cottages.

As has been insisted on before in these columns, one of the root-problems of public health is to solve the problem of cheap rural housing. Urban housing questions are complicated enough, but with energetic municipalities and cheap traction, a better era seems to be dawning. On the other hand, so long as the drift of the population is all toward the big towns, so long will urbanisation, with its toll of increased suffering and decreased longevity and health, continue to set its mark on the rising generations. Inexorable economic laws have robbed agricultural districts of much of

their prosperity and wealth, and if the labourer is to live in the land at all he must continue to be attracted by superior conditions of comfort to those obtaining in towns; moreover, these conditions must be available to his scanty earnings. Foremost among the labourer's requirements is a decent cottage, and to erect a decent cottage at a figure that will be remunerative is the puzzle of the landowners. Mr. St. Loe Strachey is organising at Letchworth an exhibition of cottages built of different materials and in different styles by various architects and builders, who are allowed a free hand to produce the best result at the most moderate price. Materials of all kinds may be used, and the results will be adjudicated upon by competent judges. It is desirable in every way that any cheap cottage that may be approved will not be banned by the building bye-laws of any district in which an owner wishes to erect one. Important as bye-laws are, and important as sanitary requirements are, there must be elasticity in their application, and it will be a vast pity if the solution of the great problem of rural housing is retarded for want of a little sweet reasonableness.

Treatment of Status Epilepticus.

SOME valuable hints on the treatment of status epilepticus are contained in a paper by Dr. Arthur Morton in the *Boston Medical and Surgical Journal* of June 15th. Dr. Morton is assistant physician to the Massachusetts Hospital for Epileptics, and he has the need for some effective means of dealing with this dangerous condition frequently before his eyes. After long-continued experiments he has found the subcutaneous injection of bromide, especially sodium bromide, not only when an attack is threatening, but also when the status is established, an important resource. He deprecates the use of stronger solutions than that of thirty grains to the ounce, as irritation is apt to be set up if the solution is too powerful, and this irritation may lead on to abscess-formation. The best site for the injection is just below the angle of the scapula, and the dose may be carried up to a hundred and eighty grains, although generally sixty or a hundred grains are found sufficient. The nurses at the Massachusetts Hospital have directions that when certain patients, who are subject to have fits in series, are taken with two convulsions following each other, that twelve grains of sodium bromide in solution are to be injected at once. If this be not successful, the dose is repeated after each convulsion, till forty-eight grains have been given, when, if status continues, the physician is sent for and thirty to a hundred and twenty grains are given by means of an antitoxin syringe. Dr. Morton has also found lumbar puncture successful in four cases out of seven, after bromide injections had failed. In one of these, patients who had had twenty-five convulsions, after the withdrawal of 20 cc. of cerebro-spinal fluid, thirty grains of sodium bromide in solution were thrown into the subdural

space, with happy results. Status epilepticus is not frequently met with in the usual round of practice, but it is so dangerous a condition that the experience of Dr. Morton is well worth attention.

The Organism of Scarlatina.

SOME year or two ago Mallory attracted considerable attention by his description of certain protozoa or protozoon-like bodies discovered by him in the skin of patients dead of scarlet fever. The bodies were from two to six microns in diameter and while some were mere oval or lobulated masses others presented a definite rosette-like appearance. This latter form suggested a similarity to the organism of malaria, and as the bodies had not been observed in any other condition than scarlatina Mallory assumes that they were present as the cause of that disease. Some little time later very similar results were arrived at by Duval, who, however discovered the bodies in blisters on scarlatina patients during life. Many intermediate forms were also demonstrated by him, suggesting the cycle of development of a protozoon. So far observation was quite in favour of regarding the bodies observed as the causal organisms of scarlet fever, although in the absence of artificial cultivation a much wider field of experiment would have been necessary. Quite recently however, observations made by Field seem to nullify those of Mallory and Duval, for while he agrees with them in finding the bodies described in the skin and blisters of scarlatina, he has also found them in measles, and he has entirely failed to find them in the skin in the stage of rash of scarlatina. Moreover, it occurred to him that the bodies observed might be leucocytes in course of degeneration, and this hypothesis was borne out by further investigation. He succeeded in fact, by suspending leucocytes in serum, in producing rosette-bodies, and other forms indistinguishable from those observed by himself and Mallory and Duval in scarlatina. While the question can hardly be regarded as quite settled, Field's observations have given a decided set-back to the protozoon theory of scarlatina.

Vaccination Proficiency.

AN order issued by the Local Government Board to the various Boards of Guardians on June 12th removes one source of needless irritation and trouble from the path of medical men who may be candidates for appointments as public vaccinators. Hitherto it has been necessary, as a condition precedent to appointment, that such a candidate should produce a certificate of proficiency in vaccination, granted after instruction and examination, unless the body from whom he received his diploma had already required such a certificate as part of his qualification to practise. This provision has meant that many men who had been in practice for years and had vaccinated hundreds of their own patients could not become public vaccinators till they had under-

gone an irritating course of "instruction" and examination in the simplest surgical operation that falls to the lot of medical practitioners. Moreover, to men not possessing such a certificate, its absence was a severe handicap in applying for the post of public vaccinator. The Local Government Board has now been pleased to relent, and allow such a certificate to be granted after examination only in the case of men who have been in practice, and they will not now have to undergo the farce of "instruction" in a little art of which they are probably past-masters. But the examination is still necessary, and a list of medical men who are competent to grant the certificates is given with great solemnity. For our own part we should have thought that a man who was not fit to perform a primary vaccination on his own account, was not fit to undertake any other surgical procedure.

Knighthood for Dr. William Smyly.

IN the list of birthday honours published a few days ago is found the name of Dr. William J. Smyly, of Dublin, the present President of the Royal College of Physicians in Ireland. It may be taken that the knighthood conferred on Dr. Smyly is not merely a compliment to the College of which he is head, but is a mark of distinction to himself personally, as one of the leading exponents of the Dublin School of Midwifery. It is not often that the College of Physicians selects an Obstetric Physician as President, and when the Fellows elected Dr. Smyly as second obstetrician in succession—his immediate predecessor being Sir Arthur Macan—they had a due sense of the lustre shed on Irish medicine by the Dublin School of Midwifery. Dr. Smyly is a native of Dublin, being a younger brother of the late Sir Philip Smyly, and is about fifty-five years of age. He graduated with a silver medal in natural science in Trinity College in 1871, and afterwards studied in Vienna. He was Master of the Rotunda Hospital from 1889 to 1896, and during his term of office much was done to carry on the line of improvements begun by his predecessor, Sir Arthur Macan. In particular it was during his mastership that the Auxiliary for gynaecological diseases was built and opened. Dr. Smyly has been President of several of the gynaecological and obstetric societies, and has contributed valuable papers to the medical journals. On his retirement from the Rotunda he was appointed gynaecologist to the Adelaide Hospital. We join his many friends in hearty congratulations on his new distinction.

Health of the Army.

THE ponderous annual report on the health of the Army has just been issued, just eighteen months after the completion of the year to which it refers—namely, 1903. It contains but few fresh features, as though the figures under each head show slight variations—and these generally

favourable ones—the old object-lessons are still present. Of these latter, venereal disease is, as usual, sadly to the fore. In India, although the strength has been reduced by 31.9 per 1,000, the admission-rate for venereal disease stands at the appalling figure of 249.5 per 1,000. It is comforting to think that the "general, commanding, regimental, and medical officers are strenuously working in concert by every means in their power to reduce it," but it is difficult to see what practical steps are within their powers. With human nature what it is, and prostitution conducted under the conditions that obtain, it is likely that this lamentable proportion, over a quarter of the full strength of European Army, will be annually in hospital with the diseases which can most truly be classed as preventible, and which bring untold misery not only to the victims in after-life, but often to their wives and offspring. Nor is it reassuring to read that out of 69,553 recruits that were inspected, no less than 22,382 were rejected as physically unfit. This means that practically a third of the presumably healthy young men prepared to serve their country are not of sufficient physique and stamina to do so, and the return for the year under notice shows a proportion of rejections higher by 14.61 per 1,000 than the previous one. Perhaps the most encouraging feature of the report is the strong way in which the Director-General speaks of the possibility of reducing the enteric fever returns. If Surgeon-General Keogh can induce his military colleagues to take this matter seriously in hand, he will have deserved well of the nation.

Death from Liquozone.

THE danger of many widely advertised proprietary preparations, although well-known to the medical profession, has not hitherto led to adequate legislative measures to protect the community. An apt illustration of the terrible risks incurred by self-medication with powerful drugs has recently been furnished in Dr. Wynn Westcott's Coroner's Court in Stoke Newington. Two children were dosed for several days with a patent medicine sold under the name of Liquozone, when they died. Dr. F. J. Smith, the well-known medico-legal authority, had no hesitation in ascribing death in both cases to Liquozone, which contained sulphurous acid. Sir Thomas Stevenson supplied the further explanation that small doses might do no harm, whereas continued dosing would have an irritant action. This explains the assertion of the proprietors of Liquozone that millions of bottles have been sold without any complaint having arisen. That fact, however, does not justify the sale of so potent a drug, or for that matter of any drug whatever for the cure of disease by non-medical persons. In this case the jury found that Liquozone killed the two children, and from that view we find it impossible to differ. An extraordinary feature of the case was that two eminent medical men—namely, Professor H. T. Pepper and Dr. Luff,

came forward apparently to give evidence in favour of the company. Mr. Pepper stated he could find no traces of an irritant poison; while Dr. Luff went so far as to say, if we may accept the newspaper reports, that in his opinion death was due to food poisoning, and in no way to be attributed to Liquezone. This difference of medical opinion is derogatory alike to the dignity of the profession and to the position of modern medical science.

Professional Philanthropy.

THE Chairman of the London Hospital, the Hon. Sydney Holland, has the courage of his opinions. On various occasions we have differed from his views, especially on the matter of the pay system in hospitals. His latest outspoken criticism is a scathing exposure in the *British Journal of Nursing* of the methods adopted by the *Hospital* journal to secure advertisements from medical charities. He quotes a letter from the canvassers of the *Hospital* saying that the sole design of the recent special Sunday supplement was to serve the voluntary institutions, and that consequently the charges made for appeals were nominal. Mr. Holland appends scales of rates charged to hospitals for advertisements in special issues of the *Hospital* and compares them with charges made to tradesmen. A whole page charge for a hospital is £7 7s., against £5 to a tradesman, or £4 if the latter applies through an agent. If we may accept these facts, they show conclusively that philanthropy does not extend to the business conduct of philanthropic journals. The plain truth of the whole matter is that the enormous income and expenditure of the medical charities furnish annually a huge interest in the way of salaries, posts, contracts, investments, and paid legal services, not to mention other patronage. Fortunes are made and titles secured by a great host of social and commercial parasites of our great voluntary hospital system. When will Mr. Holland turn his attention to the economic relations of the general practitioner to the hospitals?

Mr. Coroner Troutbeck on Rash Medical Testimony.

MR. CORONER TROUTBECK continues to urge war to the knife against the medical men of his district. His attitude is inconsistent, for on the one hand he trusts implicitly to the medical witness of his election, a self-constituted pathological "expert," while on the other he rejects the medical men of a vast London quarter. Last week this sapient Coroner held an inquest on the body of a child of 19 months, who died soon after an operation for adenoids. A *post-mortem* examination showed the actual cause of death to have been suffocation owing to the child having swallowed some milk into the windpipe. Dr. Freyberger made that momentous discovery, but surely it did not require an expert at a two-guinea fee to disclose what would have been evident to the

veriest tyro in medicine. The Coroner, fortified by this testimony from his talented protégé, proceeded to attack an absent medical man on the strength of the hearsay testimony of his own court officer. He told the jury that while inquiries were being made a certain doctor made a statement which appeared to him to be particularly rash, to the effect that the child had died of blood poisoning following operation. It seems to us particularly rash for anyone acting in a semi-judicial capacity to make public and sinister attacks founded upon remote hearsay evidence. We are glad to believe the methods of most of his Majesty's Coroners are more dignified and more in accordance with the dictates of elementary justice.

Antitoxic Action of Tears.

THE immunity of the conjunctival sac to many diseases has suggested to various observers the possibility that the tears may possess some antiseptic action. Although the conjunctiva usually contains a considerable number of germs, it does not contain by any means so many as the mouth or nose. To some infections, such as gonorrhœa, it offers an easy foothold, while to others, such as diphtheria, there is evidently considerable resistance. Demaria, who has chosen the organism of diphtheria for a series of experiments with the lachrymal secretion, has come to the conclusion that the protective action of the tears is entirely mechanical. For instance, when tears were mixed with a culture of virulent bacilli, neither the activity nor the number of the bacilli was diminished. On the other hand, if tears were mixed with diphtheria toxin, and the mixture allowed to stand for some hours, it was found to be comparatively harmless. This result, however, was thought to be due to some chemical action, as no decrease of toxicity was noticed when the toxin and the tears were injected immediately after mixture. It is probable then that it is merely by washing the eye that tears give us protection against bacterial infection.

Eugenics.

THE study of the improvement of the human race by selected breeding has, in recent times, been dignified as a science under the title heading this paragraph. The glib argument is applied that as we improve the race of racehorses or greyhounds, for example, by selection of parents, we might produce similar effects by supervising human marriages. There are, however, several fallacies in this reasoning. The two cases are not, to quote Mr. Balfour's Latin, *in pari materia*. We are able to breed fast racehorses because we want fast racehorses, just as we could breed racing men if we so chose; but the difficulty is that we do not know what ideal of man we should aim at, as no one is able to tell what type is most suitable for survival. Is it the muscular man, the tall man, the short man, or the man of contemptible

physique but giant intellect? If any one of these were the type we wished to perpetuate, we might be able to take some steps toward the desired end, but there is no agreement as to the type. Moreover, even if there were a general consensus of opinion, it would not necessarily establish itself as correct. To judge of the most suitable type we should have to know the future environment, which is impossible. Commenting on this subject, out contemporary, *American Medicine*, remarks: "If primitive man could have thought on the subject at all, he would have scouted the idea that a weakling with a hairless body would ever be the best type for survival." In the natural tendency of each individual to mate with its opposite is to be found the great safeguard of the persistence of the human race, as it is by maintaining the normal, and not by promoting wide variations, that a species is perpetuated. Although, therefore, a cut-and-dry "eugenic" system is not likely to present any advantage over natural selection, this view is by no means an excuse for the propagation of the obviously unfit.

The Old and Tattered Prescription.

A RECENT fatality in which a waiter succumbed to heart disease serves to illustrate the danger that may arise from taking medicine made up year after year from an old prescription. The man in the street loves such a document, especially if to it be attached the name of a well-known physician or surgeon, and cherishes it as an heirloom little short of omnipotent in its healing virtue. That constitutions change with years matters to him not one jot; the mystic receipt, with its cabalistic inscription, still retains its potent original charm, and must be a priceless remedy for all time. There are two chief dangers attending the use of an out-of-date prescription, one affecting the original patient and the other his friends. The continual repetition of a medicine by the same individual is most unwise—for not only may it gradually lose its effect in certain cases, but it may prove positively harmful. Powerful drugs, such as morphia, mercury, or the nitrites, are given to produce distinct temporary effects, and to continue the administration of these remedies apart from medical supervision is to court an inquest, as the above case unhappily shows. Another common and no less disastrous abuse is the practice of handing a prescription to one's friends who are supposed to be suffering from similar complaints. "One man's medicine, another's poison" is a true alternative reading of a familiar proverb that the public would do well to ponder.

Epsom College Jubilee.

ON Saturday last, Epsom College celebrated its "Jubilee." Old boys and friends journeyed from far and near to gather on the cricket-field and in the buildings of the red-brick school on the edge of the Downs. A special service of thanksgiving was held in the College Chapel. Tea was served in the headmaster's garden. In the evening, Mr

Henry Morris, F.R.C.S., presided at a festival dinner, and among the guests and friends were the Earl of Rosebery, Sir Richard Douglas-Powell (President of the Royal College of Physicians), Sir C. Holman (Treasurer of the College), Dr. F. de Havilland Hall, Dr. Frederick Taylor, Dr. T. N. Kelynack, and Surgeon-General Branfoot. There was a large muster of old Epsomians. Mr. Morris, in proposing the toast of the evening, "Success to Epsom College," sketched the history of the College and its close relationship to the medical profession, and the Earl of Rosebery in reply spoke in the most eulogistic terms of the record which Epsom College in its fifty years' life had established.

PERSONAL.

ON Saturday last the King and Queen, accompanied by the Princess Victoria, drove to Millbank to inspect the new military hospital for the reception of invalids from the whole of the London garrison. Their Majesties made a minute inspection of the buildings, including the wards, in which there were 80 patients. The hospital, when complete, will accommodate 230 patients.

PRINCESS CHRISTIAN, on the 1st instant, presented the Mary Kingsley medal of the Liverpool School of Tropical Medicine to the following gentlemen:—Dr. Laveran, of the Pasteur Institute; Sir Patrick Manson, and Colonel Bruce.

THE tenth session of the International Statistical Institute will be held in London at the Imperial Institute, South Kensington, from July 31st to August 5th next. The Honorary President of the Society, H.R.H. the Prince of Wales, has consented to act as Honorary President of the Congress, and to preside at the opening meeting on Monday, July 31st, at 11 a.m.

HER Royal Highness Princess Christian attended a meeting last week at Chelsea House at which an appeal was made for a sum of £50,000 to build the first of the sanatoria which it is intended to establish in Great Britain for the open-air treatment of members of the working classes suffering from tuberculosis.

DR. MCCALL ANDERSON, the recipient of a knighthood on his Majesty's birthday list last week, is, of course the well-known Regius Professor of Medicine in the University of Glasgow, and representative of the University on the General Medical Council.

DR. THOS. F. CHAVASSE, who was honoured with a knighthood on the same occasion, is senior surgeon to the Birmingham General Hospital, and Consulting Surgeon to several other charities, as well as an author of several well-known medical works.

DR. W. J. SMYLY, another member of the profession selected for titular honour, is the popular President of the Royal College of Physicians, Ireland, and a former President of the Royal Academy of Medicine and of the British Gynæcological Society.

AMONG the colonial honours conferred last week, Edmond Sinclair Stevenson, Esq., M.D., M.R.C.S.E., Member of the Medical Council of the Colony of the Cape of Good Hope, was knighted, and William Thomas Prout, Esq., M.B., Principal Medical Officer, Colony of Sierra Leone, also Surgeon-General William Launcelotte Gubbins, M.V.O., Principal Medical Officer Western Command, India, were made Companions of the Bath.

DR. RICHARD G. HEBB, for many years Pathologist and Lecturer on Pathology at Westminster Hospital, has recently been appointed full Physician of the Hospital.

SIR JOHN GORST delivered an address last week at the annual distribution of prizes to the students of the Medical School of St. Mary's Hospital, London.

MR. H. T. BUTLIN, F.R.C.S., distributed the prizes last week to the successful students of the London School of Medicine for Women.

THE name of Admiral Togo appears on the list of life governors of Tilbury Cottage Hospital. Some years ago several Japanese sailors, injured in an accident at Tilbury Docks, were taken to the hospital, and they were there visited by Admiral (then Captain) Togo, who was a naval attaché at the time.

PROFESSOR EMIL ZUCKERKANHDL, who holds the Chair of Anatomy formerly occupied by the famous Hyrtl, has again been elected Dean of the Medical Faculty in Vienna for 1905-6. He was called to this post of honour six years ago.

THE Council of Birmingham University has decided to invite Sir Archibald Geikie to deliver the Huxley Lecture in 1906.

DR. G. H. POOLEY, Medical Officer of the East Africa Protectorate and Uganda, has resigned his appointment.

A PRESENTATION was made to Dr. Ronald C. Macfie by the patients and staff of the Sidlaw Sanatorium on the occasion of his vacating the office of medical superintendent which he has held since the opening of the institution.

DR. J. D. SMALL, Medical Officer, Lagos, has been transferred to Southern Nigeria as Senior Medical Officer.

DR. A. D. MILNE, Assistant Principal Medical Officer of the East Africa Protectorate, has arrived in England on leave of absence.

DR. ROBERT MORTON, of Nenagh, has for some time been ill, and as a mark of the high esteem in which he is held by all who know him as a friend and a practitioner, he has been presented with a cheque for over £400, and an address. Dr. Morton is one of the most able practitioners in Ireland.

Special Correspondence.

[FROM OUR OWN CORRESPONDENTS.]

SCOTLAND.

MIDWIFERY CHAIR IN THE UNIVERSITY OF EDINBURGH.—The question of the division of this chair into two departments of obstetrics and gynaecology has, it is understood, been remitted to the University Court. Should they decide that such a course is feasible, either by the creation of a lectureship in gynaecology or otherwise, the necessary legal formalities may require more time than will elapse between now and the beginning of the University winter session, and therefore it is possible that Professor Simpson may be appealed to to continue in office for another six months, pending the reconstruction of his department. We believe that, having made the wrench involved in resigning his post, he is unwilling to do this, for obvious and natural reasons, but is prepared to sacrifice his personal inclinations if need be in order to facilitate the consummation of what he himself advocated in an introductory address to his class so far back as in 1882—viz., the creation of a separate professorship of gynaecology.

GLASGOW AND INFANTILE MORTALITY.—There has been established at Glasgow recently a new milk depot, which provides pure milk for children. As it is a fact that the proportion of deaths during infancy is much greater than at any other period, it is hoped that this new depot, where absolutely pure milk can be obtained, will be the means of diminishing the death-rate of children. The great thing that has hindered the work of the Health Committee of Glasgow in its endeavours to cope with this matter, has been the ignorance displayed by mothers in the choice of food for their children. The health authorities of Manchester and some other towns have been splendidly helped by bands of ladies, who go into the slums and teach mothers the proper food with which to feed their children. Some such plan is under consideration in Glasgow, and a start in the work may be looked for some time in the near future. The health sub-committee have before them a proposal to include among the duties of the female sanitary inspectors that of instilling into the minds of the poor the great improvement which would be effected in the health of their children, if milk obtained from this new milk depot were given to them.

VACCINATION AND SMALL-POX.—In his report for the year 1904, Dr. Wm. S. Cook, medical officer of health for Greenock, gave some interesting comparisons between the effects of small-pox on persons vaccinated and those unvaccinated. Amongst all those who were re-vaccinated during the recent epidemic in Greenock, there was not a single case of small-pox. Those persons who were in contact with the disease were all re-vaccinated, and not one took the disease; surely a splendid testimonial to the efficacy of vaccination. Of a thousand people in Greenock who had good marks of early vaccination, only 3.4 took smallpox, while of a thousand persons who had not been vaccinated, or who showed only faint marks of early vaccination, 19.8 were stricken by the disease—almost six times as many. In the case of those who took the disease, 13.9 per cent. of those vaccinated had a very severe attack, while 62 per cent. of persons with no marks had the disease in a severe form. There were only four deaths amongst those vaccinated, out of 215 cases, and two of these deaths were from complications; while there were twelve deaths out of fifty cases of small-pox in those unvaccinated. Dr. Cook finished up by saying that he had obtained good proof from the recent epidemic that, even though the effect of vaccination as a protective agency against small-pox diminished as a person drew towards middle life—if not re-vaccinated—a vaccinated person would not take the disease in a severe form, and there was very little danger of an attack proving fatal.

KNIGHTHOOD TO PROFESSOR T. MCCALL ANDERSON.—We offer congratulations to Dr. T. McCall Anderson on the bestowal on him of the honour of knighthood on the occasion of the King's birthday. He is Professor of the Practice of Medicine in Glasgow University, a post he obtained in 1900 on the resignation of Sir William T. Gairdner, who is now enjoying well-earned retirement in Edinburgh. Glasgow University has now on its staff three medical professors possessing the title of knighthood; they are Sir Wm. MacEwan, the distinguished Professor of Surgery; Sir Hector Cameron, Professor of Clinical Surgery; and now Sir T. McCall Anderson.

BELFAST.

THE SEWAGE DISPOSAL PROBLEM.—The recent spell of hot weather has brought the sewage question prominently before the Belfast public, as the stench from the shores of the lough has been quite overpowering on some days. Since the city sewage has been discharged directly into the lough by a covered channel which takes it about a mile below the city there has been a great increase in the growth of the common green seaweed (*Ulva Latissima*) on the slob-lands between high and low water-marks. This weed has been shown by Professor Letts, of Queen's College, who has

investigated the whole subject, to contain sulphur, and when it decays on the shore it gives off sulphuretted hydrogen in abundance; hence the "foreshore nuisance." The civic authorities have been experimenting, under the guidance of Professor Letts, with a view to discovering some method of treating the sewage that would render it a less suitable medium for the growth of this weed, and with this end in view have laid out bacteria beds covering about four acres. These are to be largely extended, and the inhabitants of the low part of the city close to where these beds are situated are up in arms, petitioning the Local Government Board against them. It appears from the accounts that are given by these protesting citizens that the smell from the bacteria beds is quite as bad as, if not worse than, that from the *Uva Latissima*. Without dogmatising on the methods employed, one may safely say that it is clear that the satisfactory method of dealing with the sewage of Belfast has yet to be found.

OVERCROWDING OF BELFAST WORKHOUSE.—The guardians have prepared a long report on this subject, in reply to the one sent in by the Local Government Board inspector, and recently noticed in this column, which practically amounted to a charge of overcrowding and insufficient accommodation in every department. The reply is much too long to be summarised, but the general drift might be indicated by the immortal sentence: "Don't shoot, colonel; I'll come down."

Correspondence.

THE USE OF PESSARIES UNDER DIFFICULTIES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having already written more than once in defence of pessaries. I was pleased to read in your last issue Dr. Burton's remarks, with many of which I quite agree. I cannot, however, subscribe to the statement, "The patient can be taught to take the pessary out, clean it, and re-insert it herself." Fancy a patient with retroversion or retroflexion being first able to replace the uterus, and then the pessary in the position it had been placed by the practitioner, perhaps days before! Dr. Burton says, "I have had numbers of patients who have taken them out every night and put them back in the morning before rising from bed." It would be interesting to know what the pessary was worn for? more especially if the patient is "enjoined to lie in the horizontal position" (I presume on the back, unless specially directed not to), which Dr. Burton says nothing about. If all patients wearing pessaries could "take them out" and replace to their own comfort, the visits to the practitioner (at least, in private practice) would become fewer than ever.

The sweeping statement that "no man will be successful in these cases without first putting his patient to bed," I deny. I have often succeeded in fitting a pessary (first visit) by making the patient assume the knee-chest position for five minutes or so before introducing the support (with corset and underclothing loose). Emmet says very forcibly—page 316 of his valuable work: "It is scarcely probable that those who object to pessaries will be likely to attribute their failures to some defect within themselves." Yet they may rest assured that such has invariably been the case. It is well to remember that a *healthy uterus cannot become retroflexed or prolapsed*, hence the importance of treating that organ while at the same time gaining the great advantage of the support in addition (as one would use a crutch during lameness). I quite agree with the statement of Emmet, which will go far to explain why the vaginal pessary is decried and become unpopular: "The practitioner, to become an expert in fitting a pessary that can do no harm, must have a decided mechanical talent."

I am, sir, yours truly,

London, W.

ALEXANDER DUKE.

Obituary.

JAMES MACNABB CUNINGHAM, M.D. ED., LL.D., C.S.I.

THE death took place last week, at Buckingham Palace Mansions of Surgeon-General James Macnabb Cunningham, C.S.I., M.D., LL.D., at the age of 76, who filled for many years the highest medical and sanitary positions in India, and who had been on the list of honorary surgeons to the Sovereign since 1888. Dr. Cunningham joined the Bengal Medical Service 54 years ago, and, after holding various district appointments, became Secretary to the Sanitary Commissioner and Professor of Hygiene in the Calcutta Medical College in 1869. Three years later he was appointed Sanitary Commissioner of Bengal, and in 1875 received charge of the Sanitary Department for the whole of India. When he retired, in 1885, he was awarded a Companionship of the Star of India, and three years later he became honorary surgeon to Queen Victoria.

GEORGE FREDERICK WALES, L.R.C.P. & S. ED.

WE regret to record the death of Dr. George Frederick Wales, one of the founders of the White Star Line and sixty years a qualified practitioner, at Holywood, near Belfast, at an advanced age. In 1880 he graduated L.R.C.P. & S. Edin., and was a voluminous writer on medical subjects, and a former president of the Ulster Medical Society. Three sons have adopted their father's profession, whilst a fourth holds a prominent position in the Chinese Customs. The deceased and the late Sir Edward Harland were intimate friends and not a little of the success of Messrs. Harland and Wolff, the great Belfast ship-builders, may be ascribed to his sage advice.

PROFESSOR JOHN V. MIKULICZ, OF BRESLAU.

OUR Vienna correspondent writes:—Another of the links between past and modern surgery has been broken by the death of Mikulicz, Professor of Surgery at Breslau, the famous Lister of the Continent, a pupil of Billroth, and an energetic supporter of the antiseptic treatment. The Mikulicz-tampon is a popular dressing in both Austria and Germany. Born in 1850 and educated at Vienna he has passed through all the phases necessary to qualify for the lofty position in which he has distinguished himself. He was quiet and retiring in manner and modest in conversation. His operations are legion, though his life has been a short one—fifty-five years. Among his principal operations may be mentioned the thyroid, brain, and stomach. As an author he is prolific and recently commenced a journal with Naunyn, entitled "Beiträge aus den Grenzgebieten der Inneren Medizin und Chirurgie."

Literature.

THE PRINCIPLES AND PRACTICE OF ASEPSIS, (a)

In this small manual the author, Mr. Vallack, describes in simple language a practical system of aseptic surgery. He treats the subject by giving the *rationale* of each detail in the procedure, and by citing the principles, and quoting experiments bearing on this method of surgical technique. The author may be congratulated in bringing out very forcibly many points, the full importance of which are often underrated in general surgical practice.

Mr. Vallack advocates the use of sterilised rubber gloves in septic operations and dressings. In this he agrees with the leading exponents of asepsis, since it has been found, as the author clearly points out, that it is practically impossible to sterilise the hands after contact with septic material. In this connection it is surprising to find that he does not insist upon their use in all cases by the operating surgeon. He

(a) "The Principles and Practice of Asepsis." By Arthur Styles Vallack, M.B. and M.Ch. (Sydney), L.M. (Rotunda), Surgeon to the Berrima District Hospital, New South Wales. Pp. x. and 95. London: Baillière, Tindall and Cox. 1905. Price 3s. 6d. net.

bases his objection on, the loss of tactile sense. This objection, as a matter of fact, disappears with practice.

In reference to the sterilisation of ligatures, the author points out the fallacy of assuming that catgut, &c., is sterile, when cultivation experiments give a negative result. In support of this he quotes Klemm's experiments, in which, with the same materials as used in the cultivation experiments, a specific infection was produced by inoculation.

On the whole, it would strike the reader that the author's aseptic technique is not as thorough or comprehensive as that described and practised by many surgeons. For instance, the limited sterilised area in an operation, as described on page 69, involves considerable care and anxiety on the part of the surgeon, while stitching napkins to the edges of the skin round the wound might be considered needlessly severe on the patient. If the sterilised field were larger, both these difficulties would be obviated.

CLINICAL STUDIES IN SYPHILIS. (a)

IN spite of its title, this interesting little work contains a large proportion of theory, since it is based on what the author calls the microbe-toxin theory, which, although not proved, is stated by Mr. Ward to be very generally accepted. It must be taken into consideration that Mr. Ward's theories, as theories, are put forward in a very ingenious way, especially with regard to the supposed syphilitic microbe generating the syphilitic toxin, the former remaining fixed, whilst the latter is diffused into the circulation, Colles's law being thus explained. In his description of the initial lesion, we think the author lays too much stress on the question of induration, and also that he gives a somewhat erroneous impression in speaking of the primary sore in its second stage as being a . . . worm-eaten ulcer; we think also that Mr. Ward generalises too much in saying that during the secondary latent period "the primary sore tends to grow larger, more indurated, and more callous," as in the majority of cases, according to general experience, the primary sore is a most insignificant lesion, healing readily and giving no trouble, as, for instance, in women, in whom it is even rare to see more than slight traces of the primary lesion, so little inconvenience has it caused. The portion of this work devoted to treatment is well worthy of perusal by any medical man as the outcome of practical experience.

CLEFT PALATE AND HARELIP. (a)

THE chief object of Mr. Edmund Owen's interesting little monograph is evidently, as he himself says, to bring into more general notice the excellent work which has been accomplished in the treatment of cleft palate by Dr. Truman Brophy, the president of the Chicago College of Dental Surgery. Dr. Brophy's method in operating on the cleft palate in infants consists, after paring the edges of the cleft and passing silver sutures through the substance of the maxillæ, in squeezing the maxillæ together, this being facilitated by incising the mucous membrane over each molar process and dividing the maxillæ sufficiently to enable the palatine processes to be thrust into the middle line. Although Dr. Owen says in his preface that he hopes young surgeons may find help in the pages of this little book in overcoming the difficulties of operations on cleft palate, the explanation of the operation by Dr. Brophy's method would not we think, be of as much service to the neophyte as to the surgeon skilled in operations on the palate, but, on the other hand, the description of the operation undertaken after infancy is very lucid, and the chapters on the preparation of the patient and on the care of the child after operation are very practical and instructive. The chapter on the operation for harelip is very interesting. In fact, the whole book teems with hints that should be of great value to every practical surgeon.

(a) "Cleft Palate and Harelip." (Medical Monograph Series.) By Edmund Owen, M.B., F.R.C.S. Pp. 103. London: Bailliere, Tindall and Cox. Price 2s. 6d.

DELAFIELD AND PRUDDEN'S PATHOLOGICAL ANATOMY. (a)

THE present edition of this well-known pathology has been so thoroughly revised and brought up to date by the addition of new matter and new illustrations that it practically constitutes a new book. The principal changes may be said to be, first and chief, the increased attention paid to "the relationships of pathology to the allied phases of biological science," then the exclusion "of those phases of clinical diagnosis and practical bacteriology" which are usually dealt with in special treatises, the re-writing of the sections on immunity, on the blood, and on the nervous system, and the introduction of a more complete bibliography. Changes have been also made in the authorship of the work, as Dr. Delafield has retired, and Professors Ewing, Wood, and Bailey have assisted in the re-writing of several sections. A large number of illustrations have been added.

The book is divided into three parts, the first dealing with postmortem and other forms of examination, the second with general pathology, and the third with special pathology. A longer chapter than is usual in works of this kind is devoted to the pathology of the female reproductive organs, and we suppose that more space could not be spared. If, in a subsequent edition, it was found possible to deal more fully with the complex subject of genital and ovarian pathology, it would add to the value of the book, for it is a sad fact that there is no really first-class work on the subject in the English language. We note that the author takes the view, in a very brief note, that so-called "deciduoma malignum" is most closely allied to the sarcomata. We think that his views in this respect will probably be modified by more recent literature than that he quotes, and that in his next edition he will agree that this curious tumour is derived from the epithelial coverings of the villi, and is best termed "chorionepithelioma."

For the work as a whole we have nothing but praise, and we regard it as an ideal text-book for the student or medical practitioner.

Laboratory Notes.

HUDSON'S EUMENTHOL JUJUBES.

THIS preparation comes to us with a reputation already well-established in Queensland (manufactured by G. Hudson, chemist, Ipswich, Australia). The use of sweetmeats as a vehicle for the administration of various drugs to the mucous membranes of the mouth and pharynx constitutes a well-recognised artifice of therapeutics. In this particular instance it appears well suited to its purpose. Menthol, as every one knows, is a powerful antiseptic remedy and bactericide, but it is hardly fitted for use as a gargle or spray to the throat. In the eumenthol jujubes we are presented with a menthol combination at once attractive and efficient, and as reasonably pleasant as any menthol preparation can be rendered for application to the sensitive nerves of taste. These jujubes should be of special service to lecturers, public singers, and speakers, and indeed to all who are called upon to use their voices frequently for prolonged periods.

CYLLIN.

THE introduction of Cyllin by the Jeyes' Sanitary Compounds Company marks a departure that bids fair to be of some importance in the future of practical disinfection. The preparation in question is a standardised disinfectant, so that not only its composition is constant, but its disinfectant efficiency guaranteed

(a) "A Handbook of Pathological Anatomy and Histology, with an introductory section on Postmortem Examinations, and the Method of Preserving and Examining Dead Tissues." By Francis Delafield, Emeritus Professor of the Practice of Medicine, College of Physicians and Surgeons, Columbia University, and T. Mitchell Prudden, M.D., Professor of Pathology and Director of the Department of Pathology, College of Physicians and Surgeons, Columbia University. Seventh Edition, with 13 full-page plates, and 545 illustrations in the text in black and colours. London: Bailliere, Tindall and Cox. 1905. Price 21s. net.

in accordance with a declared standard. In this way it is stated that cyllin is permanently homogeneous, and that it has a disinfectant efficiency eleven times as great as that of pure carbolic acid when tested against a vigorous culture of the *Bacillus typhosus*. It is clear that the question of price must be considered in relation to efficiency; thus, supposing a disinfectant to cost one shilling a gallon, and cyllin four shillings a gallon, but at the same time eleven times as much of the former is needed as of the latter to do a given amount of work, then it is clear that cyllin would be far cheaper in the long run. The principle of standardisation, however, happily enables us to avoid invidious comparisons. Cyllin is clearly a powerful and efficient disinfectant. It is far less toxic than carbolic acid when taken internally, and is likely to be useful in many internal complaints, and, as far as we can see, this preparation has before it a great field of usefulness.

Medical News.

Medical Fees Under the Midwives Act.

It has long been felt that some provision should have been made in the Midwives Act for the payment of a medical man who is called in by a midwife. The Cardiff Medical Society and the Cardiff Division of the British Medical Association have both expressed the opinion that the supervising authority should pay a fee to the practitioner called in upon such occasions. In Cardiff the supervising authority is the health committee of the Corporation and the medical officer of health (Dr. E. Walford) is intrusted with the administration of the Act. After conferring with the medical men in the town, the authority has decided to recommend to the Corporation that a fee of one guinea should be paid to a medical practitioner called in by a midwife if he is unable to obtain payment from the patient or from the Board of Guardians. The payment is only to be made, however, in cases of flooding, convulsions, and rupture of the uterus.

Bacteriological Department of the University of Durham.

DURING the last twelve months 1,474 specimens have been examined in the bacteriological department of the University of Durham College of Medicine, Newcastle-upon-Tyne, showing an increase of 352 over the previous year. The great majority of the specimens were examined for the various County Councils and public institutions in the neighbourhood. Out of 774 specimens of sputum examined for tubercle bacilli, 39 per cent. were found to be positive. Out of 421 cases of suspected diphtheria 38 per cent. were found to be positive, whilst from 149 specimens of blood from suspected enteric 47 per cent. were positive. Forty-eight samples of water were examined quantitatively for bacteria, and six samples of milk for *B. typhosus*. Urine was examined in twenty-five cases for *B. tuberculosis*, with five positive results. Ten specimens of blood were examined for anthrax, with seven positive results. One sample was examined for glanders with a positive result, and one sample of brawn was examined for *B. enteritidis*, with a positive result.

St. Thomas's Hospital Medical School.—Prize List.

THE annual distribution of prizes to the successful students of this Medical School took place on Wednesday last, when His Grace the Lord Archbishop of Canterbury kindly undertook the duties, and delivered an address. Prize for the Summer Session, 1904.—First year's student, J. A. Clark, College Prize, £15. The principal prizes for the Winter Session, 1904-5, fell as follows:—E. W. Witney, Entrance Science Scholarship, £150.; University Scholarships, £50. C. E. Whitehead. Second year's student: The Wm. Tite Scholarship, £25. W. B. Johnson. Third year's students: The Musgrove Scholarship, £35. R. W. Rix; College Prizes: £20. J. A. Clark; £10. H. A. H. Robson.

Medallists in Practical Medicine: G. J. Langley, The Mead Medal; H. R. Dean, The Wainwright Prize; G. J. Langley, The Seymour Graves Toller Prize; C. L. Morgan, qualified for Mead Medal. Surgery and Surgical Anatomy.—L. E. C. Norbury, The Cheselden Medal; H. T. Gray. A. W. Hooker, and J. H. Drew qualified for Cheselden Medal. Pathology and Morbid Anatomy.—A. G. Gibson, The Bristowe Medal. Obstetric Medicine.—J. M. Wyatt, the Sutton Sams Memorial Prize. For General Proficiency and Good Conduct.—L. E. C. Norbury, The Treasurer's Gold Medal.

Mount Vernon Hospital for Consumption.

YESTERDAY, Tuesday, July 4th, was the occasion for the gathering of a large party of friends of the Mount Vernon Hospital for Consumption at Northwood, when Princess Christian visited the new country branch and was present at the Garden Party held in the extensive grounds. This most complete sanatorium which has cost over £100,000 is the gift of one who desires to remain anonymous. Although only fourteen miles from London it is situated in delightful country, is readily accessible, and in every way admirably adapted to its purpose. The Committee are appealing for £100,000 to secure means for maintenance.

Death Under Chloroform.

An inquest was held at Workington last week regarding the death of Florence Woodall, æt. 31, wife of the Rev. E. J. Woodall, Baptist minister, who died under chloroform whilst undergoing a slight operation in the morning. Dr. Eadie performed the operation and Dr. M'Kerrow had charge of the chloroform. The medical evidence showed that every precaution was taken, and the jury found that death was due to accidental chloroform poisoning.

King's College Hospital.

THE trustees of the late Miss Marianne Frances Hasker, formerly of St. Leonards-on-Sea, have promised a donation of £20,000 (being part of the residue of her estate) towards the fund for the removal of King's College Hospital to South London. The only conditions imposed are that when the new hospital is built one of the blocks for female patients shall be named after the deceased, and that a brass mural tablet shall be erected thereon recording the benefaction.

Pathological Material Sent by Post.

WE have received the following from the Postmaster-General:—The attention of the Postmaster-General has been drawn to the fact that pathological specimens are frequently sent by post by members of the medical profession and other persons in packets which have not been registered as required by the Post Office regulations. The Postmaster-General desires to give notice that the transmission of such specimens is sanctioned only on the condition that they are handed in at a post-office for transmission by registered letter post, and that they are packed in accordance with the regulations published in the Post Office Guide. These regulations, which are necessary for the protection of the Post Office servants and of the public, provide that any deleterious liquid or substance sent by post must be enclosed in a receptacle, hermetically sealed, which receptacle must itself be placed in a strong wooden, leathern, or metal case, in such a way that it cannot shift about, and with a sufficient quantity of some absorbent material (such as sawdust or cotton-wool) so packed about the receptacle as absolutely to prevent any possible leakage from the packet in the event of damage to the receptacle. The packet must also be marked "Fragile, with care." Any person who sends by post a deleterious liquid or substance for medical examination or analysis otherwise than as provided by these regulations is liable to prosecution, even if he be a patient sending something to his medical adviser for his opinion or a medical practitioner sending something to a laboratory or elsewhere.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

MISS G. (M.D.Lond.).—The Governor of Algeria is preparing to establish lady doctors, with rooms, salary, &c., for the benefit of the female Mussulman population, who may not see male doctors. He proposes to put others in charge of infirmaries for natives.

STATISTICIAN.—The rate of suicide per 1,000,000 is on the increase. In 1861 it was 66; in 1881, 77; in 1891, 85; in 1901, 96; in 1903, 105. Alcohol is the most common predisposing cause.

A SKIRTLESS WASTE.

A microbe sat in the busy street;
A wretched wee wight was he;
And the tears in floods from his woeful eyes
Poured silent and frequent.
"Alas and alack! I am doomed!" he cried,
In a voice that was filled with pain,
"On the trailing skirt I may ride no more—
And my soul is the shrine of pain!"
"My heart turns back to the good old days
When over the slushy street
The soggy skirt went dragging by,
In the wake of the twinkling feet;
Oh, good old days, you are gone for aye!
And I sobbingly shriek and sigh;
For the skirt that once dragged in the filth and mud
Now travels three inches high!"

DR. F. (Donbristle).—Prof. Osler's little work on Immorality, which was delivered as an address to his students, has been followed by an article in the "North American Review" for this month on "Science and Immorality," by J. Sanderson Christison.

MR. C. H. S.—The insertion of your letter would open up a discussion on religious subjects for which our columns are unsuitable, and which it has always been our rule to avoid.

DR. D. J. JONES.—We hope to have space in our next for your paper on "Food and Feeding in Alcoholism."

DR. G. M. S.—We understand there is a new edition in the press, but are unable to confirm or negative what you have heard. We can hardly imagine the author of a standard work of such authority to contemplate so complete a metamorphosis.

A QUESTION OF TEMPERATURE.

AN old dandy was taken ill, and called in a physician of his own race. After a time, as there was no sign of improvement, he asked for a white doctor. Soon after arriving, Dr. — felt the old man's pulse, and then examined his tongue. "Did your other doctor take your temperature?" he asked. "I don't know, boss," replied the sick negro. "I hain't missed anything but my watch as yet."—*Exchange.*

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JULY 5th.

OBSTETRICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8 p.m. Specimens will be shown by Dr. Boxall, Dr. Fairbairn, Mr. Targett, Dr. Heller, Dr. Macnaughton-Jones, and Mrs. Boyd. Short Communications.—Mrs. Scharrlieb: A Case of Uterine Tumour with (?) Sarcoma or Endothelioma.—Mr. Targett and Mr. Hicks: Malignant Embryoma of Ovary.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chelms Street, W.C.).—4 p.m. Mr. P. J. Freyer: Clinique. (Surgical.) 5.15 p.m. Dr. J. Fawcett: Cancer of the Stomach.

THURSDAY, JULY 6th.

NORTH-EAST LONDON CLINICAL SOCIETY (Tottenham Hospital, N.).—4 p.m. Annual General Meeting.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chelms Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m. Dr. D. Somerville: Errors of Digestion in Relation to Disease.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (7 Fitzroy Square, W.).—5 p.m. Lecture: Mr. J. Berry: Foreign Bodies in the Air-passages. (Post-Graduate Course.)

FRIDAY, JULY 7th.

"OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11 Chandos Street, Cavendish Square, W.).—8 p.m. Card Specimens. 8.30 p.m. Papers:—Mr. C. Worth: Hereditary Influence in Myopia.—Mr. M. S. Mayou: Tubercle of the Iris.—Mr. S. Snell: (1) Sympathetic Ophthalmia (severe), Recovery of Perfect Sight in Exciting and Sympathizing Eyes; (2) Cases of Sympathetic Ophthalmia arising after Enucleation; (3) A Further Instance of Glioma in more than One Member of the same Family.—Mr. Cruise: Microphthalmos.—Mr. Nettleship: (1) Note on the Prognosis in Chronic Sclerophthalmos (Mooren's Ulcer) of the Cornea; (2) Sequel to a Case of Oxycephaly or "Tower-Skull," published in 1887, by E. Nettleship. Annual General Meeting.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chelms Street, W.C.).—4 p.m. Mr. S. Stephenson: Clinique. (Eye.)

THURSDAY, JULY 13th.

BRITISH GYNÆCOLOGICAL SOCIETY (20 Hanover Square, W.).—8 p.m. (Dr. Charles Maunsell: (1) A Case of Endothelioma Uteri,

illustrated by drawings and microphotographs. (2) An Improved Method of Ventrofixation of the Uterus, illustrated. Dr. H. Macnaughton-Jones: (1) Note on Cyllin as a Post-operative Antiseptic. (2) Note on a Case of Post-operative Parotitis. (3) Note on a Case of Urethral Cyst.

Vacancies.

City and County Borough of Chester.—Medical Officer of Health. Salary £500 per annum. Applications to J. H. Dickson, Town Clerk, Chester.

Monmouthshire Asylum, Abergavenny.—Senior Assistant Medical Officer. Salary £250 per annum, with board, furnished apartments, attendance, and washing. Applications to the Medical Superintendent.

North Riding of Yorkshire Lunatic Asylum, Clifton, York.—Medical Superintendent. Salary £800 per annum, with furnished house and allowances. Applications to Robert Holtby, 5 New Street, York.

Gateshead Dispensary.—Assistant Medical Officer.—Salary £180 per annum. Applications to W. Swinburne, Hon. Sec., the Town Hall, Gateshead.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Medical Officer of the Casualty Department. Salary £100 per annum. Luncheon at the Hospital. Applications to W. M. Wilcox, Secretary.

Parish of St. Giles', Camberwell.—Assistant Medical Officer at the Infirmary, Brunswick Square, Camberwell. Salary £110 per annum, with apartments, board and washing. Applications to the Medical Superintendent at the Infirmary.

University of Leeds.—Faculty of Medicine.—Demonstrator of Bacteriology. Salary £150 per annum. Applications to the Registrar of the University.

Royal Victoria Hospital, Bournemouth.—A House Surgeon. Salary £100 per annum, with board and lodging. Applications to J. Wycliffe-Goodwin, Secretary.

Metropolitan Asylums Board, Leavesden Asylum, near Watford, Herts.—Male Third Assistant Medical Officer. Salary £150 per annum, with rations, lodging, attendance, and washing. Applications at the office of the Board, Embankment, London, E.C.

Appointments.

BATTEN, 'FREDERICK E., F.R.C.P.Lond., Physician to the Hospital for Sick Children, Great Ormond Street.

CHARLES, JOHN ROGER, M.A., M.D., B.C. Cantab., M.R.C.P.Lond., M.R.C.S. Eng., Honorary Assistant Physician to the Bristol Royal Infirmary.

DOBSON, J. F., M.S.Lond., F.R.C.S. Eng., Honorary Assistant Surgeon to the General Infirmary at Leeds.

MAGILVRAY, W. JACKSON HOOKER, L.R.C.P. and L.R.C.S. Edin., &c., Medical Officer to the General Friendly Society, for Higher Broughton, Manchester and District.

MOORE, L. A., L.R.C.P.Lond., M.R.C.S., Dental Anæsthetist at the Bristol Royal Infirmary.

Births.

CAMPS.—On June 28th, at Udney Park, Teddington, Middlesex, the wife of Percy W. L. Camps, M.B., B.S., F.R.C.S., of a son.

LEAFING.—On June 2nd, at 23 Rushtall Avenue, Bedford Park, London, the wife of R. Craske Leafing, M.B., B.S., M.R.C.S., of a son.

Marriages.

EVERS—LONG.—On June 21st, at St. James's, Clapton, Guy Vincent, fourth son of Alfred Evers, White Hall, Stourbridge, to Kathleen Elizabeth, daughter of the late Mark Long, M.D., of Ludlow, Salop, and Mrs. Long, of Cromer Norfolk.

INMAN—TURNER.—On July 1st, at St. James-the-Lees, Nutley, William Inman, M.B., to Lena Turner, eldest daughter of Albert Turner, The Limes, Nutley, Sussex.

PARSONS—SMITH.—On July 3rd, at St. Luke's Church, Allan Chilton Parsons, of the West African Medical Service, eldest son of the late F. J. Parsons, M.R.C.C., of Portland, Dorset, to Agnes Myr-freda Hart Smith, youngest daughter of the Rev. W. Hart Smith, of Launceston, Cornwall.

POWER—STEWART.—On June 28th, at Poona, Captain William Martin Power, R.A.M.C., only son of Mrs. Power, of Dublin, to Margaret Emily Campbell Stewart, second daughter of the late Major A. F. Stewart, 36th and 23rd Regiments.

Deaths.

ABERCROMBIE.—On June 27th, at Sherwood, Colinton, Midlothian, Miss Agnes Abercrombie, in her 86th year, last surviving daughter of the late John Abercrombie, M.D. (Edin. and Oxon.), F.R.O.P., first Physician in Scotland to King William IV. and to Queen Victoria.

EVANS.—On June 6th, at Lucknow, of heat apoplexy, Staff Sergeant Ernest Haines Evans, aged 28, third son of Herbert N. Evans, M.B., of Seaford, late of Hampstead.

ASSISTANCY WANTED with a view to ultimate partnership or sole charge by a practitioner doubly qualified, aged 31, who has filled the offices of Resident Physician and Surgeon to one of the largest infirmaries, and has done a good deal of surgical work. London or Provinces immaterial.—Address, Edin., London Office of this Journal.

ABSTRACT OF THE Cavendish Lectures :

ON

DISEASE OF THE HEART. (a)

By JAMES F. GOODHART, M.D., LL.D., F.R.C.P.,
Consulting Physician to Guy's Hospital and to the Evelina
Hospital for Children.

THOSE murmurs with which I shall first concern myself are all systolic. Many are basal, and of these, some are over the aortic valves, but more over the pulmonary, extending over the right ventricle, and towards the apex. Some are loudest in the mitral area, and when so they have a tendency, like the basal murmurs, to diffuse themselves, in this case upwards, round the nipple, to join the basal one, and the two often existing together, the one merges into the other and it is difficult indeed to say if there be one murmur or two. Very often, however, there is a purely apical murmur, which is heard in a series of separate whiffs, or is intensified in whiffs. And these are clearly associated with inspiration. Two or three come in each inspiration, as it rises to its acme, and then cease again, and these may be quite well heard round at the angle of the scapula. They are most marked when the patient is nervous under examination, and the heart more or less quickened. The murmur most probably *disappears* as the heart quiets down, and in all cases it is then much diminished. Under similar circumstances there often occur impurities of sound rather than definite murmurs; the first sound loses its cleanness, and is converted into a murmurous, or humming, or groaning, or grunting prolongation, this being confined almost exclusively to the position of the impulse.

Lastly—and perhaps most common of all—there is another murmur, or the same murmur under a different aspect, again systolic and apical, and curving round it upwards towards the base, and which has this peculiarity, that it is only brought out by making the patient lie down. The heart-sounds, when examined with the patient standing or even sitting, are absolutely healthy, but put the patient on a couch, and a more or less well-marked, often quite loud systolic souffle, like that of mitral regurgitation, is developed round the apex. If a somewhat prolonged observation is made it will be found that the murmur varies considerably in intensity at different beats, and tends on the whole to disappear, after the position assumed has been maintained for some few seconds, or perhaps as much as a minute or two. Much more rarely I have heard a bruit develop when the patient rises, though there has been none when the body was recumbent. Foxwell speaks of this murmur as "the pulmonary murmur," and considers its position to be over the second and third left intercostal spaces. He alludes fully to this characteristic feature of production in the recumbent posture, and explains it by stretching of the pulmonary artery under condi-

tions of debility, and he has even known it to develop after the occurrence of heart strain.

If you make a practice of examining the heart of everyone that you see for the first time—no matter what the complaint—both standing up and lying down, I am quite sure the frequency with which you will find this systolic murmur, or these systolic murmurs, will surprise you; they are as common as movable kidneys.

These are the chief varieties of what are called "functional" murmurs. What, however, is, I think, not even yet so well known as it ought to be, or allowed for in daily practice, is the *frequency* with which they occur even in healthy subjects, unless mere temporary nervous excitement be judged to be ill-health, and this *variability* in form both between one case and another, and in the one case also, between one moment and another.

Functional murmurs have ever been supposed to convey the indication that, at any rate, there is something wrong, and mostly a blood change to be removed by an administration of iron. A proportion of them are produced in the mitral orifice; that any one of them may occur in man, woman, boy, or girl, examined it may be casually, and in whom there need be no sign of any disease, or even of disturbance of the action of the heart.

Now it seems fair to argue that being so often discovered haphazard, and associated, as they often are, with no symptoms, and being often called into being by a simple change of position of the body, they cannot be, at any rate in many cases, of first-rate importance, and I would venture to change the name of many of them from the old one of "functional" to that of "postural" murmurs.

Yet such cases are often rejected at life offices; they are refused for the public services; they come from all quarters committed to the existence of organic heart disease. So common, indeed, are such cases that it is impossible to give even a summary of them, but I will single out a few that have specially interested me or have come across my path while I have been preparing this lecture.

A common case is such as this: A tall, overgrown, nervous youth with a pulse of 104 under examination. The dulness is decidedly ample over the left side of the chest inside the nipple, and there is a diffused forcible impulse spread all over the second, third, fourth, and fifth spaces, between the sternum and the left nipple. On auscultation there is a loud systolic murmur over the pulmonary valves, a thick second sound, and at the apex a loud systolic murmur that comes in whiffs as the inspiration rises and disappears absolutely as it wanes. What could sound worse than this description, and the case can easily look grave to the examiner, but the signs need all to be seen with the individual as a background, and then they are clearly of much less importance. Deduct the nervous excitement and the long narrow chest that cramps the lungs and brings the boy's heart unusually to the fore, and then the character of the

(a) Delivered before the West London Medico-Chir. Society, Friday, June 23rd, 1905.

murmur points to the reasonable probability that the heart is a sound one.

Another case that interested me much at the time was that of a young man, æt. 22, who, having passed into the Woods and Forests three years before, was rejected at a final medical examination because he had disease of the heart. He was sent to me by Mr. Giffard, of Egham, because he could not find anything wrong. I examined his heart in all positions, and am sure it was absolutely healthy. I was so convinced that the man must have been nervous under examination and that a mistake had been made, that I wrote to the Under-Secretary of State, and he very kindly acceded at once to my request for a re-examination, but the Board adhered to its original opinion, and the candidate was again rejected on the ground that he had a valvular murmur that rendered him unfit for service in India. He had never had any trouble with his heart before, nor has he had any since, for I heard of him not long ago, and I am quite sure there was never anything more than the temporary murmur due to neuro-muscular excitement, and I hold that a young man's prospects were unnecessarily placed in jeopardy by reason of ignorance of the character of this murmur.

Once more, I saw last June a man in the Army, æt. 21. He had been sent home from India with this on his sheet:—He was about to be placed under an anæsthetic for abscess in his foot, and an examination of the heart showed the apex beat in the normal position, but also in the epigastrium, and over the right ventricle. First sound accentuated and accompanied by a blowing systolic murmur over the tricuspid area. The remark appended is that the local signs are in favour of an organic lesion, but the improvement of the man's general health pointed to a functional murmur.

I saw him with his then medical man a month or so after he arrived home, and his symptoms were chiefly a rapid nervous action. I cannot now say if there was any murmur, but I considered it essentially a nervous heart, and that there was no occasion to be anxious about his future. We lost sight of him, and he eventually went out to India again after six months' leave, and as soon as he started work and long and heavy marches he broke down again from, as he told me when I pressed him for definite symptoms, sheer exhaustion, and he was sent home "suffering from valvular disease, the effect of climate and duty." The physical signs, as recorded on his health sheet, being taken to indicate "organic mitral regurgitation with tricuspid insufficiency." But what do I find? When standing there is absolutely no abnormality of any kind. When recumbent, the heart's action becomes cantering, and there is an impurity of sounds both at the apex and base. The real explanation of the case is that he has never as yet had the stamina required for the Army, and under the stress of climate and duty he becomes played out, not in the heart more than any other muscle, and as soon as he is off duty he recovers himself as he did on the former occasion.

Many a difficulty is there with these cases, and I cannot too strongly urge the necessity of taking a more liberal view of the power of disappearance of even well-marked cardiac murmurs. There is no need to neglect them, or even to make unduly light of them. We do not know, and must wait and see. Such cases need watching and examining from time to time. It is easy to do this without committing one's self to any irrevocable diagnosis or prognosis until time has shown the way. And perhaps this applies with more especial force to childhood than to adult life. Pyrexial disturbances of all sorts are of the commonest of maladies up to ten or twelve years, and there is nothing more common during these attacks than for the first sound of the heart to develop a systolic murmur, in association with the excitement of the muscular action that is one of the common phenomena of fever. Clearly the heart in such cases requires to be kept under careful observation, lest anything escape us of permanent import to the integrity of the organ, but

there is no need to excite the apprehensions of the parents. It is a feature of the febrile reaction of childhood, and for the most part these bruits quite disappear as the fever subsides, and the child recovers its tone. In so important a matter as the question of the existence of endocarditis or valvular disease, no one should precipitately commit himself to an opinion from which it will be difficult to extricate either himself or his patient. Let me illustrate this by a case. A child has had an attack of fever of sorts. A systolic murmur has developed, and the heart is said to be affected, and the future sketched out in somewhat sombre light. The fat is all in the fire from the mention of heart's disease, and the necessity for prolonged rest. But the child was not ill; its temperature was not yet stable, and although admittedly there was a systolic murmur audible from time to time, and I think some little displacement of the impulse, I took a much more sanguine view, based upon the grounds I have already given, that the murmur was a variable one, being frequently entirely absent, and that it was also distinctly a postural one. But it was obvious that my opinion was neither expected nor acquiesced in, and I should not be surprised if that child were still undergoing that most harmful process of being shielded from his environment in every possible way because he labours under the suspicion of having disease of the heart.

Within limits rather jealously watched, I should regard dulness as a safer sign of disease than the position of the impulse. Everyone knows that great increase in the size of the heart may be present without any increase of the dulness, and on the other hand, and it is with this that I am more concerned, there may be apparent increase of dulness without any increase of the size of the heart or of its cavities. Increase of the natural præcordial dulness often means no more than an altered relation of the heart to the chest wall or surface; a change in the pulmonary circulation or inflation, and not in the heart itself. For example, in the narrow-chested people of all ages and either sex, although women and children are its best illustrants, the dulness is often large from the simple fact that the lungs are small and not fully inflated, and therefore the heart is much more extensively in contact with the chest wall in front, and under this condition in a nervous subject, to hark back to the former section, it is wonderful how masterful the beat seems to be, and there is indeed excuse for thinking the organ diseased, although it is in truth quite healthy. But then as regards dulness, I would have these remarks apply chiefly to dulness at the base, and over the right side, and very cautiously indeed, if at all, to the region of the apex. I therefore find it impossible to agree with the conclusions of those who, when they detect small differences in this area after baths and other forms of treatment, ascribe it to a reduction in the size of the heart. It seems to me that the *Nauheim* treatment in appropriate cases—not all and sundry—has indeed the warranty of *results*, but not that of any convincing topographical argument, such as its advocates claim for it.

I come next to a number of cardiac disturbances, which group themselves together under irregularities of action, and as an introduction to the subject I can hardly do better than recall to your minds all the vagaries of the action of the muscular fibre of the heart, that you may hear in any one afternoon, in the out-patient room under the excitement of examination. The noises, the plunges, the thuds, the sudden momentary stops that come; and have you not often wished, as I have done, when, as sometimes happens, the case staggers experience, and when, as I maintain, it is a more vital matter to be able to say positively that there is *no* disease, than to say there *is*, for the happiness of a life is far more linked to the verdict, "You are *healthy*," than to that other, "You are not quite sound, and you must take care of yourself," for the one means a full life, and the other a maimed one? Have you never wished, I say, that some mechanical genius would invent such a cardiophone as

would enable one to examine that heart as its subject slept, untrammelled by his nerves?

Any of these conditions may be evidence of serious organic disease and a breakdown in the near future, but in themselves they may be simple functional disturbances, and of no great moment. Taken as they come, I think it is not untrue to say that they may be regarded as trivial, or at any rate hopefully, until you have proved them to be otherwise. This applies to some more than to others. Bradycardia and pain are certainly the most ominous, but either may be temporary only. Tachycardia in like manner is often a mere nerve excitement, and of no importance, though under certain circumstances it is a most dangerous disease.

Let me say a few words about each of these separately, and perhaps as most common comes first an irregular or intermitting heart. I know not which is the more common or the less important. A heart that beats irregularly in time is very common as a transient thing. I cannot but think that many own immediately an abdominal origin; that they are caused through some waning influence on the part of the great ganglia of the abdominal nervous system.

And perhaps this will throw some small ray of light upon one or two other maladies which, although we must call them disease, it is questionable whether *qua* heart they are really so. Two are common, two are of pathetic interest, so swift, so tragic may be their ending. I will take them in their order—Graves' disease, angina pectoris, some forms of sudden death. The first-named comes properly next, as in effect it is exactly the same disease as has just been described. It differs in no other way than that it is much more likely to be intractable, and even permanent in some. No better illustration of the need for keeping separate disease and unnatural function could be given, for it will exist for years without producing evidence of disease, and it therefore affords the best possible example of the never-say-die principle that is inherent in the heart, and of the power of that organ to cope, and cope successfully, with very adverse circumstances.

Angina pectoris is not as happy in this respect, but it also has in some respects a similar history. It is well known that when anyone dies of this malady the coronary arteries are almost invariably found diseased, and although it has been a much vexed question, the disease found has come to be considered as its cause. And I think Osler at any rate has stated that in *most* cases carefully examined during life some evidence of disease about the aorta will be found to exist. I demur to both opinions.

Angina pectoris is common among us, if we are on the look-out for the milder forms of it, but then it is not for me a sudden dreadful chest pang that comes and kills within, perhaps, a few hours. That is a rare variety. It is much more a paroxysmal twinge in the epigastrium or chest, that almost invariably takes a man in walking, and apparently because he walks, and because he walks uphill, and moreover it is quite astonishing at how small an incline the anginal patient will shy. He stops and looks into a shop, and within a few seconds the pain will have vanished, and its departure is nearly always associated with the eructation of wind. So much so is this the case that it is often mistaken for a simple indigestion, which is all the more plausible in that it is a common visitant when the walk is taken soon after a meal. It is constantly finding out the city man after his breakfast. It is also a malady that comes and goes, sometimes goes altogether, but is also more usually one of the most intractable of the neuralgiæ with which we are called upon to deal, and too often it has come to stay, with intermissions. And here is the point: I have known it in two cases to last twenty years, so long, indeed that it seems impossible, at least unlikely, that the disease that was found at the last was indeed present at first. I have certainly examined these

mild cases by the score without finding any trace of disease of the heart, and all my later experience confirms me in saying what I said years ago in this respect, that the pain is best explained by regarding it as a neuralgia, or storm, that emanates from the great abdominal brain, although I was inclined at one time to regard it as a cramp of the heart.

It might perhaps be thought that the very generally accepted association of vascular tension with angina is adverse to this opinion, and so I think it might be. But I have never yet accepted this view of angina pectoris for more than a small proportion of cases. I say—assured in my own mind that I am right, although it is contrary to the opinion of the most experienced men—that as a rule there is no increase of tension; I have had my finger on the pulse all through a spasm of angina many a time. Angina is, if anything, a disease of low tension, as is to be expected of a crushing pain that emanates from the pit of the stomach.

Now I wonder whether you have followed my drift, for I must confess, as I retrace my own thoughts, that innocence and guilt seem to have been somewhat incongruously mixed; I must often have seemed to have been straining at a gnat and swallowing a camel. Nevertheless, this endeavour to bring within *proper limits*, and only this, the significance of some of the common forms of departure from the normal function of the heart, is directed to the diagnosis, treatment, and prevention of real disease. Discussing a questionable case of heart disease the other day, it was said to me, "There is no disease; the heart is only a little dilated and fatty." But what more disease can you ask? It points well my moral, which is this: that all these ailments that I have mentioned, oft-times trivial, oft-times transient, are too often but pegs upon which to hang a diagnosis of dilatation of the heart, and in the present day we make much too free use of this diagnosis. I regard dilatation as one of the worst of all the heart's diseases, and to play with such a term is to play with a torpedo. Surely dilatation, save in exceptional circumstances, should be reserved for a disease that is associated with some series of definite symptoms, not made dependent, as over and over again it has been, upon the mere fact that the impulse can be felt to beat in the nipple line, or even, perhaps, a little beyond it; or upon the presence of a transient murmur.

I must not go so far as to say that dilatation cannot exist without symptoms, for in the obscurity that surrounds sudden death it may be that it can; still, it must surely be an exceptional occurrence, and I think one ought to expect that, ever in slight degrees, some of the signs of a failing circulation should exist, and among these I emphatically do *not* include either giddiness or fainting. Disease of the heart seldom, if ever, causes either. I have often said this before, but it is a point that still needs insisting upon.

But there are other terms in general use that I like little better than this one of dilatation, because they have come to mean too much. One of them is "heart strain."

Years ago there was a discussion at one of the Societies upon aneurysm of the aortic arch, and I having made the remark that it was practically an incurable disease, as judged from the evidence of the *post-mortem* room and the museums—and so it is—Sir William Broadbent promptly and felicitously retorted that the *post-mortem* room was not the place to look for cures! I was quick to see then that what seemed an obvious truism did but dissemble the truth, but to-day, and here I am older and I now see that other face, with fuller meaning, which then perhaps I sighted. And so I have availed myself of the honour you have done me to discourse to-night in other terms upon the buoyancy of life, and to preach that it is not well to seek too much for the dead among the living.

ARTERIAL TENSION IN DISEASE.

By Drs. BOSCH AND VEDEL,
Of the Faculty of Medicine of Montpellier.

[SPECIALLY REPORTED FOR THE MEDICAL PRESS
AND CIRCULAR.]

THE study of arterial tension in disease comports two principal divisions—*viz.*, symptoms associated with hypertension and symptoms associated with hypotension. The first thing to do in regard to the first category is to establish a minimum figure beyond which the tension may be considered as excessive, although it is impossible to lay down a hard and fast line, seeing that the average pressure in the radial artery is extremely variable, according to the age of the subject and what we may term the congenital cardiovascular resistance. Extensive observation justifies us in stating that hypertension exists whenever the sphygmomanometer applied to the radial artery gives a figure higher than 18 cm. of mercury in the adult, and 20 or 21 in the aged.

Symptoms associated with hypertension are frequent in proportion to the very large number of conditions capable of raising arterial tension. The three factors concerned in regulating normal tension—that is to say, an increase in the blood mass, stronger cardiac action and modifications of calibre of the arterioles—may exert their influence, but changes in the peripheral circulation play the foremost part in the production of hypertension, whether the cause act directly on the vessels or induce such change *via* the nervous system. Symptoms associated with hypertension may be due to mechanical, reflex, or toxic causes. Hypertension due to mechanical causes exists only in rare instances, and is of its nature ephemeral. If the increase be moderate in degree, restoration to normal soon takes place, while if it be due to structural changes in the heart or vessels it soon gives place to hypotension in consequence of fatigue of the myocardium. These remarks also apply to hypertension of reflex origin, and more particularly to hypertension of cerebral origin, such, for example, as powerful emotion. It must, however be borne in mind that severe repeated nervous excitement may, in the long run, give rise to general disturbances of nutrition capable of determining permanent auto-intoxications with vascular sclerosis. In such case there is permanent hypertension of complex origin.

Toxic causes may be divided into *endogenous* and *exogenous*. Auto-intoxications associated with hypertension are due to enhanced toxicity of the products of metabolism followed by retention consequent upon reduced activity of the eliminatory or glandular structures. This modification of cellular activity constitutes the bradytrophic diathesis which, though usually hereditary, may be induced in its integrity under the influence of a sedentary life, constipation, overwork, or as a result of intoxication of gastric origin. These facts explain the existence of dyspepsia with hypertension. Pathological modifications of glands with an internal secretion, modifications which may be solely dependent upon phases of organic evolution (puberty or the menopause) may be productive of the same result by slowing the oxidation processes. These causes will act with the greater force in presence of a well-marked, pre-existing bradytrophic heredity with hypertension and arterio-sclerosis.

It is necessary to insist upon the fact that poisons of exogenous origin act in much the same way as those of endogenous origin. Thus, apart from the vascular spasm produced by the direct action of lead, chronic plumbism culminates in such an extreme degree of slowed nutrition that the manifestations resemble those of gout with its uræmia, periarticular reactions and generalised arterio-sclerosis associated with marked hypertension.

Whatever be the nature of the toxic agent, endogenous or exogenous, the morbid processes may culminate in symptoms of acute intoxication of the same

type (uræmia, eclampsia and plumbic headache), so that there is no necessity to invoke any one factor, such as hypertension, to explain the similarity of symptoms, the similarity of action of the toxic causes being itself sufficient to account therefor.

Poisons of microbial origin, exerting, as they do, an acuter and directly degenerative and destructive action, give rise more particularly to phenomena of hypotension. This, however, may be preceded by a period of hypertension, and, on the other hand, certain toxins (staphylococcus aureus, pyocyaneus and mallein) appear to possess pronounced hypertension-producing properties. Whether hypo- or hyper-tensive, microbial poisons—that of scarlet fever especially—determine inflammatory phenomena which persist long after the original cause has disappeared and culminate in generalised arterio-sclerosis specially localised in the heart, kidneys, or brain.

Dissatisfied with the intoxication theory, Dr. Vaquez has raised the question whether, instead of invoking the influence of products of tissue metabolism in general, it would not be better to incriminate one particular hypertensive substance. In view of the well-known influence of suprarenal extract on arterial tension on the one hand, and of the frequency of lesions of the adrenals in infections and intoxications on the other, he has arrived at the conclusion that symptoms associated with hypertension, especially trophic nephritis, may be due to excessive functional activity of the suprarenal glands, just as in the morbid condition described by Sergent and Bernard under the name of *hyperperinephritis*. Personally, though we are not concerned to deny that lesions of the suprarenal glands may have a share in the production of symptoms associated with marked hypertension, we prefer to regard these lesions less as a direct cause of the hypertension than as a defensive reaction against hypertensive poisons.

The evolution of the lesions associated with symptoms of hypertension runs through three phases. The first stage is one of spasm, the functional phase, which may be prolonged, but in the course of which supervenes a purely histological perivascular inflammatory process. This phase corresponds to that described by Huchard as the presclerotic stage, but which would be more accurately designated as the præfibrotic stage. The second stage is that of generalised fibrosis of the small vessels which determines progressive miopragia of the organs; it is the phase of fibro-capillaritis, revealed at the autopsy and capable of detection by careful clinical examination. The last phase is characterised by extension of the fibrotic process to the large vessels—*i.e.*, generalised arterio-sclerosis, followed, sooner or later, by atheroma.

We must also mention the states of partial hypertension which are due, for the most part, to arteritis, but which we cannot deal with exhaustively in the absence of the necessary data. In respect of the symptomatology, we must ask ourselves whether hypertension is *per se* capable of directly determining grave local and general disturbances, such as homonymous hemianopsia, transitory aphasia, amaurosis, headache, glaucoma, and the convulsive crises of uræmia and eclampsia. Dr. Vaquez calls attention to the fact that amaurosis, homonymous hemianopsia, and transitory aphasia present one feature in common—*viz.*, that they coincide with the hypertension and disappear when this subsides. But the exaggeration of the hypertension, together with the symptoms just referred to, may possibly both be explained by a passing intensification of the toxic cause upon which the entire syndrome is dependent. All the active causes in these cases are vaso-constrictive and give rise to spasms observable by the aid of the ophthalmoscope, so that these symptoms and the hypertension are both dependent upon the same mechanism, although the two do not stand to each other in the relationship of cause and effect.

The same reasons hinder our admitting the hypertensive nature of the paroxysmal convulsions of uræmia, eclampsia, plumbism, &c. Moreover, if the purely

mechanical theory of uræmic convulsions and eclampsia could be substantiated, it would be difficult to explain the rapid action of bleeding in bringing about the subsidence of the convulsions. The removal of, say, fifteen fluid ounces of blood has little effect on arterial tension, but along with the blood is eliminated a sufficiently large quantity of poison to calm, at any rate, the cortical irritation.

It may be asked whether, in case of generalised arterio-sclerosis with renal lesions, the crises of hypertension may not be determined by the retention of a substance not itself toxic, but exerting a hypertensive action. According to certain authors, the retention of chloride of sodium in the organism is capable of determining this result. Personally, we are unable to concede that such is the case, and we feel justified in maintaining that the hypertension is not due to variations in the elimination of chloride of sodium, but that we are dealing with substances subject to the same laws of retention and elimination as the salt in question.

In view of the very large number of primary and secondary cases of hypertension it is obvious that therapeutic indications must necessarily be complex, and that prophylaxis and general hygiene must be accorded a conspicuous position in the treatment. The recognition of the primordial cause of the hypertension is indispensable, especially in cases of recent intoxication, in which its early removal may suffice to bring about permanent recovery. In cases in which the immediate removal of the cause is not practicable, and in those in which the organism has become deeply impregnated therewith, our only hope lies in organotherapy which exerts an unquestionable antitoxic action. With regard to infectious diseases, which are usually associated with hypertension when fully developed, the treatment must be continued after apparent recovery in order to prevent, or to bring about, the immediate subsidence of sclerotic processes leading to hypertension. The treatment must be particularly energetic in diseases which, like scarlet fever, are powerfully hypertensive and sclerosing from their onset.

The alimentary regimen indisputably occupies a foremost place in the therapeutics of hypertension. Not only must gastronomic excesses be forbidden, but we must also avoid all causes capable of increasing the spasm or of provoking or aggravating the sclerosis. In cases of renal insufficiency milk diet should be ordered. As a general rule an exclusively milk diet, indicated more particularly in pronounced hypertension with marked lesions of the heart and kidneys, is well borne, provided it be alternated with a lacto-vegetarian diet or an achloric meat diet. Constipation must be overcome by repeated purgation and, in addition, we must prescribe saline aperients, which constitute an active eliminatory medication in the same manner as sudorifics and diuretics.

When the spasmodic phenomena are complicated by sclerosis of the arterioles we must avoid all causes capable of provoking attacks of hypertension which may threaten the integrity of the fragile arterioles (emotions, physical strain, coitus, &c.). It is also important to bear in mind that drastic purgatives, such as jalap, should under these conditions be given cautiously, the patient keeping his bed for two or three hours after ingestion in order to avert any reflex of gastric origin or syncope due to cerebral anæmia.

In the treatment of permanent hypertension, anti-spasmodic and hypotensive treatment can at best only yield palliative results. It is indispensable to aim at the resolution of the sclerotic lesions, and with this object in view we may prescribe iodide of sodium *in small doses* (2 to 10 grains in the twenty-four hours), suspending the treatment from time to time and giving, in the intervals alkalies, intestinal disinfectants, and sulphate of soda, for the purpose of promoting the elimination of the iodide.

When the morbid process has reached the stage of arterio-sclerosis and atheroma, resolute treatment, though useless in respect of the organic lesions, may still be of service in arresting, or promoting recovery from, the sclerotic lesions still going on in the small

vessels of the new formation. But the most important thing under these conditions is to guard against the fragility of the arterioles and to avert hæmorrhage consequent upon rupture by obviating attacks of hypertension.

Before entering upon the discussion of syndromes with *hypotension*, it may be well to define exactly what we mean by this term. A pressure of 12 or 13 centimetres of mercury represents actual hypotension; from 10 to 11 marked hypotension; 8 to 9 well-marked hypotension, and 6 to 7 an extreme degree of hypotension. In pathological states the hypotension may be dependent upon a great variety of factors which may be classified as mechanical, nervous and toxic-infective. Among the mechanical causes we may mention copious or repeated hæmorrhage, exaggerated loss of liquid *per vias naturales* (copious diarrhoea, obstinate vomiting, profuse sweating, marked polyuria), pleural, and especially pericardial, effusions which hinder the pulmonary circulation, &c.

In regard to the action of the nervous system in the production of hypotension, a prominent part must be assigned to vaso-motor disturbances of nervous origin. In point of fact, among the nervous causes of hypotension, cerebral affections occupy a foremost place. Of all the causes of hypotension, the most important from the practitioner's point of view are those associated with toxic influences, the term intoxication being interpreted in its widest sense so as to include chemical, organic, autochthonous, and microbial poisons. Although a few rare microbial toxins may, under certain circumstances, raise arterial tension, the majority, on the contrary, lower the pressure, acting, though with more or less marked predilection, both on the cardiac muscle fibre, on the small vessels, and on the nervous system. The present state of our knowledge of hypotension in toxic-infective maladies is such that we must refrain from formulating precise conclusions in respect of prognosis and therapeutics. It follows that the hypotension usually observed in the course of typhoid fever must not be considered separately, but must be viewed in conjunction with other sources of information, more particularly the examination of the heart and the pulse. The fact remains that in many cases the practitioner will derive material assistance from observation of the radial tension even in regard to prognosis. Bearing in mind the usual tension curve in this disease—in which the hypotension is tolerably irregular (15 to 12) at the period of development, with a diminution coinciding with the deferescence (13 to 10) with irregular augmentations, we must be on our guard in presence of unduly pronounced oscillations which may foreshadow important complications. When, in the course of the disease, the more or less lowered tension suddenly rises to 17 or 18 cm., we are justified in apprehending intestinal hæmorrhage.

In variola the hypotension sets in early and attains its maximum at the stage of suppuration (Reynaud and Cotte). A hypotension of 11 cm. during the first day or two indicates a grave attack, and cases in which it falls to 9 or less almost invariably prove fatal. In influenza the degree of hypotension is in direct proportion to the gravity of the infection. Drs. Jourdin and Fischer, more particularly in respect of the pulmonary form of the disease, observed that convalescence was protracted in proportion to the duration of the period of hypotension after subsidence of the fever. Pneumonia is likewise accompanied by hypotension. In mild cases the pressure hardly ever falls below 14, and returns to normal towards the twentieth day. In graver attacks it may fall to 10, and does not return to normal until the thirtieth day. In fatal cases it falls from the onset to 9 and less (Francois and Reynaud). It is, however, desirable to take the other local and general phenomena into account before committing oneself to a grave prognosis, even in presence of very pronounced hypotension.

In respect of pleurisy the tension is reduced only when the effusion is considerable in amount. Persistence of the hypotension after thoracentesis points

to the probability of a recurrence. If the tension reached 18 or 20, kidney disease is to be apprehended. On the other hand, when it falls to from 14 to 11, the fact is suggestive of tuberculosis. In the last-named affection the hypotension assumes great importance, and may be observed before any other certain physical manifestation. This means that the existence of hypotension is capable of rendering great assistance in the differential diagnosis of tuberculosis and other morbid processes more or less resembling it, or of which it may simulate the appearances. We must not forget, however, that in some tuberculous subjects the tension remains normal; indeed there may be slight hypertension.

From the point of view of therapeutics, hydrotherapy appears to be the most efficacious of the general measures having for object to re-establish arterial tension. The cold bath appears to be the most active, but the gradually cooled bath and wet packing act in the same way, though less energetically. The warm bath has a marked action on arterial tension, and it has been methodically employed in the treatment of hypotensive infectious diseases in children. This measure is specially indicated whenever the state of the heart, hæmorrhage or extreme youth constitute a contra-indication to the use of the cold bath.

Although hypotension is usually merely a symptom, and its special treatment forms part of the general treatment of the disease, there is one particular medication that is generally conceded to fulfil the rational treatment of this condition, in that it combats at one and the same time all the factors that contribute to bring it about—*viz.*, copious saline injections. In regard to adrenalin, its influence on arterial tension is extremely ephemeral, and its action exposes the patient to a whole category of accidents, consequently it should only be employed with great caution.

SOME NOTES ON FOOD AND FEEDING IN ALCOHOLISM.

By D. J. JONES, M.B., C.M. EDIN.,
Deputy Coroner for South Brecknockshire.

AMONG the many problems which the physician is called upon to face from day to day, there is none more difficult and responsible than that presented by alcoholism, both in its acute and chronic forms. To deal with it at all effectually demands the readiest and ripest resources of his professional knowledge and experience. Not only must he understand alike the weakness and the strength of human nature, and possess a working acquaintance with all known drugs, but he must also take into consideration every detail of his patient's environment. Thus alone can he bring back to temperance and health the victim of the craving for strong drink, a habit that causes a vast proportion of the misery and crime with which our modern life is unduly weighted. In his efforts to deal with the individual the physician will gradually learn how to attack the great problem of national intemperance. It is only by prolonged and painstaking labour that he may one day hope to stay the monster that devastates society with the plagues of crime, disease, insanity, suicide, and racial degeneration.

It is trite to say that temperance reformers often injure their cause by inadequate knowledge of the subject of alcoholism. Nevertheless, that is the simple truth. It needs little acquaintance with their literature to show that for the most part they lack necessary information upon many important aspects of the failing against which their crusade is directed. Their one and only

remedy for alcoholism is total abstinence. For many reasons that method, however desirable upon abstract grounds, cannot be applied to individuals on any great scale. They fail to recognise that they are dealing with persons whose will power has been undermined and that without attention to such surroundings as food, exercise, and amusement teetotalism alone is in many instances foredoomed to complete and speedy failure.

Nevertheless, it must be confessed, on the other hand, that medical science has not hitherto supplied any full and adequate classification of alcoholism. That step must logically precede sound conclusions as to the causes and effects, to say nothing of the treatment of the craving for stimulants that seems to be inborn in mankind of all races and all climates, and, so far as that goes, of all time.

Without attempting to go into details it may be stated broadly that the ill effects of alcohol upon the human body are due mostly to its action:

(1) As a direct nerve poison, in which capacity it impairs the moral and intellectual sense; (2) as a direct irritant of the liver, kidneys and other organs, which it gradually undermines and destroys; and (3) as an indirect cause of starvation of tissues.

The field thus mapped out is a large one, and it is proposed here to discuss the last-mentioned only, namely, the chronic malnutrition or starvation of body tissues due to alcoholic abuse. By "abuse" is meant not only the excessive drinking that ends in intoxication, but also the insidious form which has been happily described by an American author as "immoderate moderate drinking." In this case the victim never gets drunk, and would indignantly reject the suggestion that he was not absolutely temperate in his habits. Yet these "quiet" drinkers are those specially prone to disease of internal organs and to premature death. They are the bane of insurance societies, and fill our gaols, workhouses, and lunatic asylums. In almost all cases they are deaf to the appeals of the temperance reformers.

One symptom, common to all phases of alcoholism, is impaired appetite. This is due partly to the deranged stomach, and partly to the fact that alcohol is in many cases used as a substitute for food. Beyond a doubt the latter foolish practice enters largely into what is known as industrial or misery drinking, to overwork, bad air, insanitary workshops and dwelling-houses, and other defects of environment. To a less degree a similar substitution is involved in convivial or luxury drinking, when sherry and bitters or a whiskey "peg" takes the place of the sandwich and biscuit and the plain non-alcoholic drink which would be far better fitted to eke out the physiological income of the individual than mere alcohol. As everyone knows, the more a man drinks the less he eats. The man who has been in his cups overnight can eat no breakfast next morning, but he is generally ready to add fuel to fire and to substitute further alcohol in place of solid food. The "immoderate moderate" drinker and the chronic tippler eat little either at breakfast or at any other time. The solitary and rare exception is the man of originally strong constitution who lives an active open air life and who is able to eat well in spite of an excessive consumption of alcohol. Exceptions, however, here appear to prove the rule, for it seems impossible to avoid the conclusion that in all likelihood

the liberal amount of food is the saving clause in his exceptional case. It is the good average nutrition of his tissues that keeps him alive, just as it is the lack of nutrition, otherwise chronic starvation, that destroys his less hardily constituted fellow-drinkers.

Food furnishes the key to the situation. It is of little use to bring rest and calm to the excited brain unless due provision be made at the same time for the proper nutrition of the nerve tissues. It is not generally recognised that an overtaxed and over-stimulated brain needs not only rest, but also free and sustained nourishment. To quiet the brain by sedatives and narcotics will not bring relief to the disordered cells, which, as a matter of fact, stand in need of feeding far more than of physic. Hence the wise physician does not neglect the lore of the invalid kitchen. When faced with a patient whose tale of chronic malnutrition is told in pale face and thin body, who eats and sleeps badly, who, in short, is half starved, he straightway proceeds to ring the changes upon a long list of viands, and jellies, soups, meat extracts, pre-digested foodstuffs, dainty concoctions of cream, sugar, cereals and fruit, oysters, delicate fish, marrow, sweetbreads, and what not, are pressed into his skilful service.

Modern science, let us hasten to say, has recently strengthened the physician's hand a hundredfold by the introduction of a new food, to wit, sanatogen, which has simply revolutionised the whole art of invalid feeding. The wonders brought about by this new preparation are no less manifold than amazing. They have been testified to by leading physicians whose names are as household words in many countries of the world. The substance is simplicity itself; it is of a floury nature, and is beaten up and taken with milk or cocoa in teaspoonful doses, or may be added to any kind of broth or bouillon or soup or beef-tea, or even to custard or arrowroot or gruel. It is readily absorbed by the stomach and has an immediate and remarkable effect, shown by a steady increase of body weight and of muscular strength and energy. Patients who have grown thin as the result of chronic maladies put on flesh at the rate of one or two pounds per week, or even more in some instances. At the same time the colour is brought back to the patient's cheeks. That this last-mentioned result is due to a specific increase of red blood corpuscles has been shown by repeated and skilled examination of the blood of persons going through a course of feeding by sanatogen.

Equally good results are met with by the administration of this new remedy in acute diseases attended by wasting and prostration. It stays the appetite in a way attainable by no other means in the hunger that usually marks the recovery stage of typhoid fever. Its feeding and sustaining properties are invaluable in the complete loss of appetite that often spells danger in attacks of influenza. To nourish the patient then becomes a matter of life or death, and under these circumstances the supreme importance of highly nutritive and absorbable food in small bulk is recognised. Much more might be written under this head did space allow. The only other point, however, that will be attended to here is the most recent and in many ways the most remarkable field of usefulness to which sanatogen has hitherto been applied—namely, in the treatment of acute

and chronic alcoholism. There are obviously two ways in which it may act as a remedy—namely, as a curative and as a preventive remedy.

1. *As a Curative Agent.*—Attention was drawn to this point by a distinguished English physician who found remarkable results both in acute and chronic alcoholism. His experiences have been confirmed by other medical men, and it is not too much to say that a new chapter has been already added to the therapeutics of alcoholism. The explanation of the good results is probably simple enough. Sanatogen supplies the much-needed nutrition to the brain cells as well as the necessary fillip to heart, stomach, liver and other organs of the body. As a consequence the patient sleeps; his energy of mind and body is gradually restored and he takes exercise and gradually returns to his natural occupations and amusements. Last, but not least, his brain being in a healthier condition, he loses his depression of spirits and is afforded another chance of regaining self-control as regards his besetting evil habit. To sum up the position shortly: the balance of his nutrition has been restored, and with it his chances of recovery both for the time being and permanently have been many times multiplied.

The value of sanatogen in this condition is well illustrated by the following case recently published by Dr. Robert J. Carter:—

A married woman, *æt.* 36, had for many years given way to habits of intemperance. She was never distinctly intoxicated, but her general appearance indicated that she was imbibing far more alcohol than was either wise or necessary. She had lost most of her good looks, her face was always flushed, her hands were tremulous, she was unable to write even the simplest letter in the morning or the early hours of the day, and her temper was distinctly irritable. Her moral tone had deteriorated, and although in a good social position, she was seen on more than one occasion coming out of a low public house not a mile from her residence. She was catholic in her tastes with respect to drink, and usually commenced in the early morning with a pint of old ale, followed by a wineglass of green Chartreuse. Many attempts were made to reclaim, and for a time she was in a home for inebriates. There was an improvement, but it was soon followed by a relapse. A trip to Scotland, with plenty of outdoor exercise, improved her assimilative powers, but in no degree diminished the craving for alcohol. Large doses of perchloride of iron were given, but had no effect other than producing severe constipation. Sanatogen was then recommended, and agreed admirably. She was honestly anxious to get well, and the sanatogen apparently improved her will-power to such an extent that gradually she diminished her allowance of alcohol, and suddenly, to the astonishment of her family, became a staunch teetotaller. She has taken no stimulant for six months, and one is justified in hoping that her cure will be permanent.

The following is an equally instructive case:—

An officer in the Royal Navy contracted habits of intemperance which ultimately led to his retirement. On the China station he suffered from malaria and sunstroke. His family history was a bad one, many of his immediate relatives being alcoholic. He was readily affected by stimulants, a couple of glasses of whisky and water depriving him of all self-control. His bouts of intoxication

were intermittent, but they were severe and of long duration. Whilst in this condition he was lost to all sense of decency. He was for six months in a retreat, spending most of his time in the open-air and devoting his attention to gardening and poultry-farming. He celebrated his discharge by drinking heavily for a week, until he was on the verge of delirium tremens. Hypnotic suggestion was then essayed but this too failed. A large sum was paid by his friends for a gold-cure treatment, but this proved worse than useless. Various drugs, such as atropine, injected hypodermically, red cinchona bark, capsicum, and other similar reputed remedies seemed only to increase his craving for drink. Finally, his medical adviser suggested a trial of Sanatogen. The morning vomiting from which for many months he had suffered ceased. His appetite improved, his face assumed a more healthy aspect, and at the expiration of a fortnight his red blood corpuscles had risen from 4,000,000 to 4,500,000 per cm.—a gain of half a million in a comparatively short time. The improvement in the condition of his blood was also indicated by the fact that the hæmoglobin had increased by $4\frac{1}{2}$ per cent. This was a distinct inducement for continuing the treatment which was persevered in steadily. At the expiration of a month the craving for stimulants was much less marked and the condition of his blood, as shown by repeated tests and examinations, had still further improved. He has taken Sanatogen now for six months and since the first week he has had no outbreak. It would appear that in this case the Sanatogen acted not only as a food, but in virtue of the easily assimilable form of phosphorus which it contains, as a nervine tonic, supplying that stimulus to the higher centres of the brain and spinal cord necessary to overcome the habit of a life-time.

2. *As a Preventive Agent.*—Here, again, it is necessary to insist upon the fact that the terrible curse of drink craving, apart from mental unsoundness, is often a simple expression of overwork or of general malnutrition. It is clear that anyone who fails to take a sufficient amount of food must sooner or later induce a condition of anæmia. Nor is it less understandable that the anæmic person of either sex should turn to alcohol in the natural desire to stimulate a feeble heart. A more rational plan of treatment would seek a cardiac stimulus in food rather than in alcohol. As a matter of fact, the value of a carefully regulated and systematic dieting in the treatment of alcoholism has never yet been adequately recognised by medical authorities.

The following case illustrates the value of Sanatogen in incipient cases of alcoholism:—

A bank clerk, æt. 21, the son of a widow, gradually acquired the habit of taking alcohol to excess chiefly in the form of "nips" of whisky or of sherry or sherry and bitters in the morning or during the luncheon hour. There was no craving for stimulants in the ordinary sense of the word, but the young man was extremely anxious to obtain promotion, and, being of a delicate nervous constitution, fell into the belief that stimulants taken at frequent intervals would the better enable him to do his work. His failing was noticed by his superiors, and he was plainly told that unless there were a speedy improvement his position would be forfeited. He fully realised the gravity of the situation, but was unable of his

own will to stop the habit. At his mother's request he determined to give sanatogen a six months' trial. It answered admirably, and he has abjured whisky and sherry and now takes only bitter ale, and that in moderate quantities at his mid-day meal and at supper.

It may be useful to conclude this article by a brief note on the main points to be attended to in the treatment of alcoholism.

1. Stop alcohol absolutely in acute cases; and, whenever possible, in confirmed and in immoderate moderate drinkers.

2. Remember that alcohol is a good servant but a bad master. It is not a necessity but a luxury of life.

3. Procure sleep and soothe the worn-out nerve centres.

4. Ensure the regular and effective action of the skin, liver, kidneys, and other organs of the body.

5. Place the patient under the most favourable conditions obtainable as to warmth, pure air, exercise, amusement and wholesome surroundings generally.

6. Attend above all things to the nutrition. Feed your patient systematically with sanatogen for months together. Remember that in all cases it acts as a powerful stimulant to the nervous system, exciting to more vigorous action the weakened will-power and affording the protection so necessary to resist the insidious effects of alcohol. It can do no harm, and opens up a prospect of permanent recovery. Such patients, however, are apt to be careless and untrustworthy, and it will, as a rule, be necessary to insist that the food is taken regularly and to accept no alternative excuses. At the same time it is desirable not to neglect careful treatment by drugs, which now and then are of incalculable service, although alone they are as a rule powerless either to prevent or cure alcoholism.

Little argument is needed to prove the un-wisdom of lecturing an intemperate man while his brain is starved and simply shrivelling up for lack of nourishment. The logical course is first to feed his brain cells and then later try to instil the precepts of common sense. It is of little use, again, to give ordinary food to a man whose powers of digestion are certain to be more or less impaired by the use of stimulants. Sanatogen, on the other hand, is a perfectly ideal food for the purpose, inasmuch as it is readily absorbable, but also possesses nutritive qualities of the highest value. As an agent in the cure and prevention of all stages of alcoholism, so far as one can see, this new preparation constitutes one of the most powerful weapons ever placed in the hands of the medical profession.

THE PSYCHOLOGY OF THE INEBRIATE. (a)

By T. CLAYE SHAW, B.A., M.D., F.R.C.P.
Lecturer on Psychological Medicine, St. Bartholomew's Hospital.

THE title of the paper suggests that the mental processes of the inebriate are defined and are induced, that they are *sui generis*, a kingdom with a debased coinage, at times difficult to tell from the ring of the true metal. The result of inebriety is a changed *ego*, which has its proprium

(a) Abstract of paper opening a Discussion at The Society for the Study of Inebriety, Tuesday, July 11th, 1905, held in the Rooms of the Medical Society of London.

of external and internal characteristics. If self-analysis is difficult, how much more so is it to penetrate the motives and feelings of conditions of which we have no experience. The purport of this introduction is to draw attention to the external manifestations of the inebriate mind; to enter reliably into the subjective condition would require the experience of an inebriate de Quincy to confess oneself a converted inebriate recognising even for such an one the difficulty of contrasting past with present states of feeling and of reviving memories which are already weakened by the prominence of new images. At the base of satiety is the strong feeling which we call a "craving." Life is full of "cravings," some leading to harmful indulgence, others simply to the degree of repletion necessary to maintain the due balance of metabolism, and just as there are physical, so are there psychical cravings. Factors in cravings are time, habit, and periodicity. Appetite is the index of a want in the system; it may be described as the *somatic index* for the normal body, whilst craving is that of the artificial or disordered one. Habit means that an artificial state has been set up, which can only be changed by the stoppage of the supply of material which feeds the changed conditions, just as on the mental side we must have an entire change of ideas to get rid of an obsession. Is this then the pathology of inebriety? Does it point to an altered physical state which requires its own particular mode of nutrition? If so, we must endeavour to appreciate that modification of tissue with its attendant feeling. At present this knowledge is impossible for us, inasmuch as we do not even know the nature of feeling, nor of its association with other nervous processes. We do not even know whether when an individual can take enormous quantities of alcohol without visible impairment he owes his immunity to his stomach or to a particular composition of his nervous system.

One of the chief objective features of the inebriate is *suspicion*, seemingly due to a condition of toxæmia setting up excitement of the peripheral nerves and particularly disorganising the muscular element of thought. The key to this condition is best explained by Dr. Bevan Lewis, and the theory is a very plausible one. It rests on the evolution dogma that what is last acquired and is the most voluntary in any conscious content is, in degeneration, the first to go. As a result of his devolution there is engendered a feeling of resistance and a disposition to attribute this to some person, ending eventually in a change of the *ego* which proceeds to develop the new individuality and to mould all things to the perfection of the new state.

From this point of view craving is not so much a question of sensuous indulgence as an urgent compulsion to supply a necessary food, the individual all the time having a positive loathing of the course he has to go through to acquire the end which becomes an irresistible and compelling force. Other features of the inebriate are mental restlessness and explosiveness, the co-ordinates of a wasted inhibition. The former is due to increase of subject-consciousness and loss of the sense of awareness leading to doubt and uncertainty in his social accommodation, and therefore to explosiveness in his sudden desperate efforts to right himself.

Wundt's elaborate theory that social environment is the ultimate cause of will, affords a corroboration of the above explanation of the

impulsive condition of the inebriate. Emphasis is here placed on the motor side of the lesions in the inebriate, as shown in the paralytic form of speech, the tremors, the giddiness and the difficulty in orientation leading to the need of paying attention to the footsteps and hence to walking with the head downward and the eyes fixed on the feet. From these lesions spring agoraphobia, or the fear of walking across open spaces, shyness, self-seclusion, and lying (the latter to make excuses for his peculiar conduct and for his social offences), the reputation for laziness, for extravagance.

Secondary impairment of the heart and of the capillary circulation account for many of the social laches of which the inebriate is guilty. Special notice was here drawn to the rise in sexuality and in religious demonstration in this class of persons and reasons for the new display given, the paper concluding with an explanation of the symptoms of moral degradation, and a plea for commiseration with this unfortunate class who are really the victims of disease, occasionally showing in their disordered flashes of memory the remains of former intellectual accomplishments which could only have been achieved by patient work and an originally artistic temperament.

Clinical Records.

LIVERPOOL NORTHERN HOSPITAL.

Case of Strangulated Hernia followed by Chronic Intestinal Obstruction from Adhesions.

Under the care of K. W. MONSARRAT, M.B., F.R.C.S.E., Surgeon, David Lewis Northern Hospital, Liverpool.

ON August 9th, a man, æt. 51, was admitted to the Northern Hospital, suffering from strangulated inguinal hernia. He had had a hernia for fourteen years, for which he had not worn a truss; of late years it had been about the size of his fist, and was always down. On Saturday night, August 8th, he had a sudden violent attack of pain, referred to the hypogastrium and the rupture; this continued during the night and the rupture became larger; he vomited frequently from the time the pain commenced until his admission to hospital on the evening of the following day.

On admission he was found to have a scrotal hernia, the size of a large cocoa-nut; the house-surgeon's notes say "a Rugby football," but this is rather an exaggeration; the scrotum was tense, tender to handling, bluish-purple in colour, and tympanitic to percussion. At the operation the contents of the hernial sac were found to be small intestine; the gut was intensely congested, but except for a greyish-purple patch on the entering coil at the neck of the sac, did not show evidence of marked damage; the peritoneal coat was intact over this patch, and resection was judged unnecessary. There were several feet of gut in the sac, and there was some difficulty in returning it to the abdomen.

There was an evacuation of the bowels on the day following operation, and no pyrexia for four days; after this he commenced an evening rise to about 100° to 101°, and complained of slight general abdominal pain. This continued for three weeks. The pyrexia was somewhat puzzling, as there were no physical signs to account for it, and all the man complained of were the vague general abdominal pains already alluded to. He was allowed up three weeks after the operation, and during the following week the pyrexia disappeared; he then commenced to define his abdominal pain as restricted to the right iliac region, and constipation became troublesome. The right iliac pain persisted; on palpation here there was local tenderness, but no other abnormal physical sign. On October 14th I opened the abdomen in this region and found a mass of intestinal coils, matted together by adhesions, and bound down to the parietal peritoneum;

the affected small bowel formed a complicated coiled mass, and there was distinct compression by adhesion at one particular point, above which the bowel was somewhat distended, while below it was comparatively collapsed. After freeing the adhesions and suturing the omentum in one or two places to cover the raw surfaces thus left, I closed the abdomen. This operation was followed by entire disappearance of the constipation, local pain, and local tenderness, and the patient was discharged from hospital on November 20th. The condition was therefore one of local plastic peritonitis following damage to the gut by strangulation, resulting in the formation of firm adhesions which so matted together the affected section of the gut that intestinal obstruction was caused thereby.

This complication following strangulation is one which is of course recognised as occurring in a small proportion of cases. No doubt local peritonitis occurs to a greater or lesser degree in all strangulated herniæ, except perhaps those which are very early relieved; it is exceptional for it to proceed to the formation of the tough adhesions which were found in this case. I am not aware that this complication can be foreseen, except in so far as the degree of damage caused to the gut points to the probability of considerable local inflammatory reaction. It indicates that simple mobility is not the only point to be considered when deciding whether a portion of gut is to be returned to the abdomen; in other recorded cases this post-operative obstruction from adhesions has ended fatally. It is useless to be dogmatic as to the circumstances under which resection of gut is a wise proceeding; every case is a problem in itself, particularly in regard to the advisability of subjecting the patient to a prolongation of the operation. Where the general condition is good, the indications for reaction are extended; where the general condition is bad, as in this case, more risks must be taken, and the case illustrates one of several which should be borne in mind.

Transactions of Societies.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

THE annual Provincial Meeting was held on June 17th at the Hospital for Children, Sheffield, Dr. C. H. WILLEY in the chair.

Dr. C. N. GWYNNE showed cases of congenital dislocation of the hip, congenital dilatation of the colon; multiple tuberculous foci, infantile paralysis of the leg treated by arthrodesis, calcaneo-valgus treated by arthrodesis, excision of the knee for tuberculous disease, and (?) Hodgkin's disease.

Dr. WILLEY showed a case of pseudo-hypertrophic paralysis.

Dr. J. H. WILKS showed five cases of congenital dislocation of the hip; strangulated hernia in a baby two weeks old, successfully treated by operation; paralysis of the 3rd, 6th and 7th nerves; a huge nævus which had recovered without treatment; and a case of congenital pulmonary stenosis.

Mr. SIMON SNELL showed cases of blindness from congenital defects.

Mr. S. E. MORTON showed cases of malformation of the spine and side; malformation of the hand; Dupuytren's contraction of the hand; and enlargement of the liver.

Dr. H. LEADER showed three cases of Erb's paralysis, and one of splenic enlargement.

An extremely interesting and beautifully prepared series of pathological specimens was exhibited by Professor ARTHUR HALL to illustrate (1) hydrocephalus; (2) tuberculous tumours of the brain and cerebellum; (3) abscesses of the brain; (4) meningitis; (5) granular kidneys; (6) Hodgkin's disease; (7) meningocele; and (8) cirrhosis of the liver.

Other specimens shown were:—Congenital obliteration of the bile ducts, by Dr. J. G. EMANUEL; imperforate anus, by Dr. WILKS; and the kidneys and mediastinal growth from a case of lympho-sarcoma by Dr. LEADER.

Dr. GWYNNE read a paper on a case of OSTEOMYELITIS AND SUPPURATIVE PERICARDITIS in a girl, æt. 7, successfully treated by operation in 1903. The osteomyelitis affected the femur and radius. Incisions were made. Parotitis and pericarditis followed in three days. The pericardium was laid open ten days later, giving exit to about ten ounces of pus. A tube was inserted and removed on the tenth day. Further pyæmic complications ensued, but the child ultimately recovered. The apex of the heart was now about half an inch inside the nipple line, in the sixth space.

Dr. G. CARPENTER and Mr. S. STEPHENSON reported a case of

TUBERCLE OF THE CHOROID,

with certain peculiarities, in a girl, æt. 3. A very large number of fawn-coloured tubercles, in size up to that of the disc, were found almost exclusively near the optic disc. A diagnosis of acute miliary tuberculosis was made. Death resulted thirty-three days after the onset of the illness, nineteen days after admission, and five days after the diagnosis was made. Apart from the eyes the condition could not have been diagnosed with certainty during life. The peculiarities were the number and size of the tubercles, and the invasion of the retina by the tubercles.

Mr. J. JACKSON CLARKE drew attention to some practical points in the

TREATMENT OF CONGENITAL DISLOCATION OF THE HIP by Lorenz' method. Under anaesthesia the shortened muscles, viz., adductors, hamstrings, ilio-psoas and rectus femoris must be fully stretched. In children over four years of age the adductors may require division by subcutaneous tenotomy. The great trochanter must be brought down to, or below, its normal level. He then described the act of reduction, the mode of application of the first retention apparatus, the subsequent use of massage and exercises, and the management of special cases.

Mr. R. C. DUN described a case of median hare-lip, a very rare deformity. The cleft was exactly in the middle line, the incisor teeth perfect, and there was no alveolar cleft.

Mr. H. S. CLOGG read a paper on

APPENDICITIS IN A HERNIAL SAC,

based on the cases of two boys, æt. 3 and 8, successfully treated by operation. He estimated that 25 per cent. of recorded cases occurred in children, and mentioned that it had been reported in quite young infants. He stated that the appendix in a hernial sac was unusually prone to inflammation; that the condition could not be differentiated from strangulation of the appendix or of Meckel's diverticulum; that most cases were mistaken for strangulated hernia because of the sudden onset, abdominal pain and the presence of a local irreducible swelling, without impulse on cough. The presence of fever from the onset, the indefinite character of the swelling, and its small size, and the early occurrence of œdema and redness of the skin were of diagnostic value.

Dr. GWYNNE read a paper on two cases of multiplex xanthoma; Dr. WILKS, on a case of sudden death after needle puncture for supposed empyema, with specimen; Mr. A. H. TUBBY, on osteomyelitis of the spinal column; and Dr. LEADER on a case of Hodgkin's Disease.

ULSTER MEDICAL SOCIETY.

THE annual meeting of this Society was held in the Medical Institute, Belfast, on THURSDAY, June 29th. In the absence of the President, Dr. Calwell, the chair was taken by the ex-President, Dr. JOHN CAMPBELL.

The annual report was read by the hon. sec., Dr. T. HOUSTON. It showed some falling off in the membership during the year, chiefly among country members. The total loss of members from all causes was twenty-one, while ten new had been elected. The members lost by death were Dr. W. A. McKeown, Dr. Owen Praeger, and Dr. John McClatchy. The Council reported, with regret, that the hon. treasurer Dr. W. B. McQuitty, and the hon. librarian, Dr. R. R.

Leatham, had resigned their posts. The Council recommended the appointment of an editorial secretary to attend to the collection of papers and their publication in the Transactions, and also recommended some minor alterations in the rules. The adoption of the report was moved by the hon. sec., seconded by Dr. Kevin, and passed. The statement of accounts was read by the hon. treasurer, and showed a balance at the beginning of the financial year of £153, and at the end of it, £155, the subscriptions of fellows and members amounting to £280 7s.

The hon. librarian's report was read by Dr. HOUSTON, in the absence of Dr. Leatham, and adopted.

Sir WILLIAM WHITLA moved, and Professor LINDSAY seconded, that the best thanks of the Society be accorded to Dr. McQuitty and Dr. Leatham for their long and valuable services to the Society in the offices of hon. treasurer and hon. librarian respectively. This was passed by acclamation.

Professor BYERS called attention to the death—just taken place—of an old member and ex-president of the Society, Dr. G. F. Wales. Though long retired from active practice, many of the senior members of the Society could remember him well in his active days, when his advice was much valued and sought after by his professional brethren. Professor Byers moved that the hon. secretary be instructed to convey to the surviving members of the family the sympathy of the Society in their bereavement. This was seconded by Dr. DEMPSEY, and passed.

The following were elected office-bearers for the next session:—President—Dr. Wm. Calwell (second year of office). Vice-Presidents—Dr. J. C. Martin (Portrush), and Dr. J. R. Davison. Hon. Secretary—Dr. Thos. Houston. Hon. Treasurer—Dr. Victor Fielden. Hon. Librarian—Dr. W. L. Storey. Hon. Editorial Secretary—Dr. Howard Stevenson. Council—Drs. D. P. Gaussen (Dunmurry), Robt. Hall, John Morrow, W. B. McQuitty, R. C. McCullough, and D. McKinney, together with the seven trustees, Drs. John Campbell, Dempsey, Lindsay, McCaw, Mitchell, Nelson and Cecil Shaw.

Dr. McQUITTY showed a case for diagnosis, a man whom he had just seen in the Royal Victoria Hospital. The patient was a man of about 55, with nothing of note in his family or personal history, till the last year when he had suffered from several attacks like the present one, though not so severe. Each attack began with a feeling of burning and tingling in the stomach, which soon spread up to the throat, rendering swallowing difficult. These sensations spread in a few days to the arms, hands, legs and feet, always in the same order, and following the tingling and burning came a copious rash, which ended in free desquamation, such as might be seen after a smart attack of scarlatina. The hands were peeling freely when the patient was shown. There was no temperature or general disturbance, and all the organs were found normal. Dr. McQuitty said that the case was, to him, quite unique, and he could find no record of a similar one.

NORTH EAST LONDON CLINICAL SOCIETY.

THE Annual General Meeting of this Society was held at the Tottenham Hospital, N., on THURSDAY, July 6th, 1905, the President, Dr. R. MURRAY LESLIE, in the Chair.

The Council reported that the past Session was noticeable for the excellence of the material presented at the Clinical Meetings, which has led to a very considerable increase in the average attendance of members. The following gentlemen were elected as officers for the ensuing Session, 1905-6:—*President*, Dr. C. E. Hutt; *Vice-Presidents*, Drs. G. P. Chappel, F. H. Daly, J. W. Hunt, R. M. Leslie, G. N. Meachen, F. J. Tresilian, and Messrs. W. Edmunds, and R. F. Tomlin. *Council*, Drs. J. Beddow, H. Corner, R. E. Foott, A. E. Lermite, E. H. May, E. F. Willoughby, and Messrs. R. P. Brooks, W. H. Paine, A. de Prenderville, T. Rushbrooke, C. R. Salisbury, A. S. R. Wainwright. *Hon. Treasurer*, A. E. Giles; *Hon. Librarian*,

A. J. Whiting; *Hon. Secretaries*, H. W. Carson and G. P. Chappel.

A garden party was afterwards held in the grounds of the hospital, which was largely attended by the members and guests, including ladies.

The annual dinner of the Society was also held on Friday evening, July 7th, at the Abercorn Rooms, which was well attended, a capital musical programme being provided.

France:

[FROM OUR OWN CORRESPONDENT.]

PARIS, July 9th, 1905.

PITYRIASIS VERSICOLOR.

THE treatment of pityriasis versicolor can be abandoned to the fancy of the physician as to the choice of antiseptic solutions. It is thus that the number of parasitic remedies is considerable. While some prefer a solution of perchloride of mercury, others are content with carbolic soap, iodine or ointment of eucalyptus or creosote. One of the best and cleanest remedies, however, is the following:—

Borate of soda, 1 drachm;
Oxygen water (12 vol.), 6 oz.;

to be rubbed on the parts night and morning.

GOUT.

Iodide of lithium, 1 grain;
Extract of gentian, q.s.;

for one pill three or four daily; or—

Iodide of lithium, 1½ drachms;
Syrup of bitter orange, 7 ounces;

two or three tablespoonfuls a day; or, if chronic nephritis be present—

Extract of stigmata maydis, 1½ drachms;
Benzoate of soda, 1 drachm;
Carbonate of lithium, 1 drachm;
Oil of aniseed, 3 minims;

divide into 60 pills, two at each meal for twenty days a month, and continue three years.

HÆMORRHOIDS.

Chrysarobine, 15 grains;
Iodoform, 9 grains;
Extract of belladonna, 10 grains;
Vaseline, 5 drachms;

externally.

Chrysarobine, 1 grain;
Iodoform, 3 grains;
Extract of belladonna, ¼ grain;
Cacao butter, ½ drachm;

for one suppository.

PRURITUS OF THE ANUS.

Bichloride of mercury, ½ grain;
Hydrochlorate of ammonia, 3 grains;
Phenic acid, 1 drachm;
Glycerine, 2 ounces;

Rose water, 5 ounces;

to be applied night and morning.

Hydrochlorate of cocaine, ½ grain;
Cacao butter, q.s.;

for one suppository.

ANTISEPTIC OINTMENT.

Antipyrin, 1 drachm;
Salol, ½ drachm;
Boric acid, ½ drachm;
Iodoform, 15 grains;
Phenic acid, 15 grains;
Corrosive sublimate, 2 grains;

Vaseline, 7 ounces;

for general use (Réclus).

CEREBRO-SPINAL MENINGITIS.

Iodide of potassium or sodium have been tried in the recent epidemic of cerebro-spinal meningitis with negative results. M. Ruheman publishes a successful case treated by iodate of soda. A boy of 13 was in a hopeless condition, but made a rapid cure under the influence of the following treatment:—

Iodate of soda, ½ drachm
Water, 4 ounces;

half a tablespoonful two or three times a day.

The same author recommends subcutaneous injections of the iodate as near the head as possible (back of neck, shoulders)—

Iodate of soda, 15 grains;

Eucaïne, 6 grains;

Distilled water, 5 drachms;

one or two syringes morning and evening.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, July 9th, 1905.

At the Surgical Congress, Hr. Garré, of Königsberg, spoke on the

SUTURE OF WOUNDS OF THE LUNGS.

He said that surgeons were very backward in suturing large wounds in the lungs when threatening symptoms were present from hæmorrhage. The mortality in such injuries was very high; statistics of over 700 cases showed a mortality of over 70 per cent., and if only the more serious cases were included it would be much higher still. If the present results were compared with those of pre-antiseptic time no essential advance could be shown, as patients still died first from internal hæmorrhage, secondly from thoracic tension, and thirdly wound infection, as the internal wound was not treated at all, or only when it was too late, and when pleurisy and the further sequences had already set in. The speaker first addressed himself to internal hæmorrhage which was an urgent indication for operation, especially if Lauerbach's apparatus was at hand, or when Brauer's own pressure process could be made use of. But even if these aids were not forthcoming, there was no contra-indication of operation, as the lung was already collapsed from the wound made in it, so that fresh symptoms of collapse need not be feared from operative procedures; on the contrary the breathing would be much easier from the drawing in of the lung in the wound of the thorax, whereby the lung was shut off from the outer air. The speaker mentioned a case of subcutaneous rupture of the lung that was brought into hospital the third day after the accident, the patient being in a condition of great distress from dyspnoea. After drawing the lung forward the breathing was much easier. A boy, æt. 11, was brought in in a state of cyanosis and a pulse of 132 to 140. There was extensive hæmopneumothorax on the left side. The thorax was at once punctured, but without any improvement. Thoracotomy was then performed, the lung was drawn forwards and a rent was found 5 cm. in length and 3 in depth, which was closed by five sutures. After this the lung regained its size quickly. Death took place in two days it is true, but the indications were not the less valid, considering the fortunate results that have been obtained in other cases. Eight cases of the kind were recorded in the literature of the subject, with six successful results, following suture of the lung. He proposed thoracotomy and suture of the lung, only in cases of serious hæmorrhage into the thorax, and in cases of repeated hæmorrhage and where tension was not relieved by puncture alone.

As regarded technique he had practised on animals. One should not be afraid of narcosis, the wound should be free, in order to be able to draw out the lung easily. In case of internal hæmorrhage it was best to get in laterally, in external hæmorrhage from the wound itself. The collapsed lung was then drawn into the wound by forceps, the injured part being next sought for, and after careful cleansing the sutures were to be inserted, and to prevent them tearing out, not too near the edge of the wound. Silk sutures were the best. Wounds near the hilus could only be tamponaded, extensive bruised wounds should be brought outside.

In answer to a question as to the treatment of the pleural cavity he said he packed lightly and only closed definitely when there was subcutaneous hæmorrhage; the open treatment gave the best results. He would perhaps put in a deep drain in case of infection.

Hr. Rehn recommended the preliminary shutting

off of the pleural cavity, as the breathing would be rendered very much easier by it, if we were compelled to open later on.

Hr. König shut the pleural cavity off if there were grave symptoms of pressure change. In general it was not so dangerous to work in the thoracic cavity without Lauerbach's apparatus which cost about £800 (16,000 m.). According to experiments he had made, animals were very little affected by wounds of the thorax and lungs. He had observed the same thing in about a dozen men. He had only seen one fatal case from unilateral injury to the lung. But he would not go into the lung without urgent cause such as a foreign body, even without suture adhesion and closure took place rapidly, and a wound in the lungs was fatal only when a large vessel was injured, and when a large bronchial branch was cut through, out of which such a large quantity of air escaped and with so much force that closure by suture was not possible.

Hr. Garré observed that infection was much more dangerous in the human subject than in animals. These dangers were avoided by operation. A large bronchial branch might be closed by suture, but the edge of the wound must be freshened and a double suture applied.

At the Medical Society Hr. Ewald showed a patient with

EXTREME STENOSIS OF THE ŒSOPHAGUS

from drinking lye in mistake for white beer. When he first saw the patient a fortnight ago she was very much reduced; the stenosed part could not be passed with the finest sound. By means of the œsophagoscope the gullet could be seen to be firmly closed by a bright red membrane. As the patient could still swallow liquid in small quantities, there must be a small passage left, and for this reason the speaker persevered day after day trying to find it. Finally on the twelfth day he did succeed in discovering it under the guidance of the œsophageal tube. He was now able to pass a whalebone sound 3 to 4 millimetres in diameter, when the head was bent forwards, so as to put the œsophagus on the stretch. All soft sounds were unreliable as they bent too easily.

Hr. Mosse showed two females with

VASOMOTOR TROPHIC NEUROSES.

The first, a woman, æt. 41, after lying ill in bed a long time noticed coldness and pain of the fingers. They were not enlarged, but cold and blue, and the sensibility was not disturbed. There was bilateral catarrh of the apices, no anomaly of the nervous system. The symptoms had remained unchanged a long time.

The second case was that of a woman, æt. 39, who, after being delivered of a still-born decomposing foetus showed hyperæmic thickened patches about mouth, eyes, nose, and chest; the hands were thickened the skin rough and cold. The bones in the right hand were seen by Röntgen light to be atrophied; there was painless œdema of various joints, no disturbance of sensations. The case was diagnosed as one of scleroderma.

Examination of the blood showed fewer erythrocytes in that taken from the fingers than in that from the lobe of the ear. This was the case in both patients.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, July 9th, 1905.

ANTI-PYRENE EXANTHEMATA.

LOEBL showed a patient, æt. 34, who had from time to time suffered from severe affections of the mouth, accompanied by an exanthematous rash. The last attack commenced on the first of the month, about three in the afternoon, which was carefully observed in order to determine the cause. The first subjective symptoms were a feeling of paralysis of the tongue, pricking and itching of the lips, cheeks, and tongue itself; two hours later the tongue was greatly swollen, making articulation difficult. About seven o'clock,

or four hours after the onset, transparent vesicles, ranging from the size of fine shot to that of a bean. In many places they were confluent, and after the clear fluid exuded a tender sore was left. Three days later two large blisters rose on the hard palate, while other smaller ones were observed on the lips and inside of the buccal cavity, all covered with a deposit like plaques muqueuses. The smaller number were on the gingiva. The temperature was 39° C., 102.0° F., with a retrogression in the pathology from the first.

The diagnosis was easily recognised as stomatitis ulcerosa, but the etiology was more difficult to determine. Dermatologists had been consulted on former attacks, who advised her to consult a dentist about her teeth, which were repaired and removed, according to his judgment without any appreciable benefit. There was no taint of scorbutus to be suspected; nothing except the taking of antipyrin. On the second day of the illness, it may be mentioned, the patient had a feeling of creeping and itching in the lower limbs, leaving blisters after these had passed away; the back of the hands had at the same time a dark blue colour which extended down to the finger-ends with considerable œdema. This disappeared the following day, leaving a blister 3 by 1½ centimetres long on the left arm. These symptoms disposed of a local cause which demanded wider investigation.

Closer inquiry elicited from the patient that she had been taking powders for headache. At one o'clock, *i.e.*, two hours before the first phenomenon is recorded, she had taken one of these powders for her headache, which consisted of 0.2 gramme of phenacetin, and 0.8 of migränin; the latter is a compound of antipyrin, caffeine, and citrate, containing 80 per cent. of the former, or 6.4 gramme of antipyrin or 9.876 grains per dose. She confessed that the former attacks came on after taking the powders, but gave it no more thought. Treatment consisted of a gargle of hydrogen peroxide and insufflations of anæsthesinorthoform, and avoid antipyrin in future by substituting maretin, which is more reliable for headache.

ANEMIA SPLENICA.

Bleier presented a female to the society with splenic anæmia, who at one period of the disease had all the symptoms of pernicious anæmia, with confirmatory blood-tests.

In May, 1904, she came to Mannaberg's clinic complaining of extreme weakness, vertigo, exhaustion, and palpitation which had gone on during the four previous months.

The examination confirmed the external appearance of anæmia gravis, the liver slightly enlarged, while the spleen was enormous. The blood with Feischel's hæmometer was 18 to 20 per cent.; number of red blood corpuscles was 800,000; colour index, 1; and the number of white blood corpuscles, 5,100. When coloured the dry preparations revealed poikilocystosis, with microcysts, numerous macrocysts, and nucleated red blood corpuscles forming a sort of normoblasts; but no megaloblasts were present.

The white corpuscles, for some reason or other, had 40 per cent. of lymphocytes, probably at the cost of neutrophile-nucleo-polymorphic cells, which were 53 per cent., while the eosinophile were 3 per cent., transitional 2 per cent., and mastocells, 2 per cent. No myelocys were present.

During her two months' residence in hospital the first half was almost negative. Gradually in the second half she began to improve, but rapidly at the end. After the sixth week the megalocyst was not to be found; poikilocysts less, with very few normoblasts. The percentage of lymphocytes fell to 42. Hæmoglobin 42 per cent., erythrocyte 2,800,000, and colour index 1. Along with this improvement, general strength, and vigour returned, and a month later was able to accomplish her former duties with comfort.

The blood examination now gives a steady return of hæmoglobin, 50 to 60 per cent.; red corpuscles, 3,500,000 to 4,000,000; while the leucocytes range from 7,000 to 9,000. The last special examination gave polynuclear cells, 80 per cent.; eosinophil, 2 per cent.;

transitional, 2 per cent.; mask-cells, 2 per cent.; and 14 per cent. of lymphocytes. The liver by this time had assumed its normal proportions.

Schur thought these cases were of immense interest to the clinical observer, as they stood on the border-line of malignant and non-malignant. He related the history of a similar case that came under his own observation which had been diagnosed as pernicious anæmia, with every hæmatic proof present, yet the patient recovered as in the above case. It clearly proves that splenic enlargement, lymphocytosis, macrocystic anæmia, and all the other symptoms of that fatal disease may be present and yet prove innocent.

ICHTHYOSIS CONGENITA.

Riehl next showed a female child, æt. 1½, enveloped in a case of ichthyosis from birth, which, he remarked, was still alive. The peculiarity of the case was the absence of any real cause. This was the second child of healthy parents, the first being healthy and perfectly normal; neither was there consanguinity. The little patient was stunted in development, appearing like a child of one year, although bright and happy in all its movements, and healthy otherwise, except the skin. The head was quite encased in a thin horny covering, with tufts of hair penetrating it at frequent intervals. Both ears were embedded in folds of the horny mass, and fixed to the side of the head. The upper lids of the eyes were imperfectly developed, while the lower were short and ectropion in appearance, standing far out from the bulb, with the conjunctivæ red and inflamed. The whole trunk is bound up as a warrior in a coat of mail, varying in thickness from 1 to 2 millimetres. The arms and legs were similarly covered, but thicker at the joints. It might be noted that the lower part of the trunk, and particularly the genitals, were free from keratosis, as well as the point of the nose, alæ, and lips, which were normal.

Newman said the case was of special interest from it living so long. Children with keratosis universalis are either still-born, or die shortly after birth. All these cases assume the same appearance of thickening of the epidermis, deep fissures, from respiratory movements, or intra-uterine flexures. The cases usually observed are insular and not universal, as in this case.

Operating Theatres.

NORTH-WEST LONDON HOSPITAL.

CHOLECYSTOTOMY.—MR. MAYO COLLIER operated on a woman, æt. 52, who had been admitted under his colleague, Dr. Harry Campbell, the senior physician, suffering from well-marked jaundice with considerable enlargement of the abdomen. The past history of the case was that the patient had been apparently before this seizure free from all serious illnesses. She had not suffered previous attacks of jaundice nor was there a history of biliary colic. The present illness dated back six weeks, when she noticed that she became jaundiced and that her abdomen began to get larger and continued to do so up to the date of her entering the hospital. On admission, the patient was intensely jaundiced, the motions were seemingly free from bile, but the urine was of a very dark colour. There was no sickness, no elevation of temperature, and the woman retained a moderate appetite. The chest cavity was apparently free from disease; the abdomen was much enlarged, but free from ascites and contained a well-marked enlargement in the right and upper half. On inspiration, the mass was evidently large, and it moved upwards with expiration. The lower limit of the swelling approached the iliac fossa, and here a distinct elastic cyst-like mass could be felt. Mr. Collier considered that this case was with little doubt one of enlarged gall-bladder, probably due to impaction of a calculus in the common duct, and with

the consent of his colleague he decided to open the abdomen, and if, as he had expressed his opinion, the gall-bladder was enlarged from its outlet being occluded by a calculus, to cut down and remove the obstruction if possible. An incision was made on the outer border of the rectus a little below the umbilicus; on the abdominal cavity being opened the liver was found to extend some two inches below the umbilicus, and the gall-bladder some four inches below this. The gall-bladder was enormously distended, being the size of a small cocoa-nut. The peritoneum was free from adhesions and inflammation, and there was no fluid in the peritoneal cavity. Mr. Collier, having tapped the enlarged gall-bladder with a trochar and withdrawn over half a pint of bile, stitched the gall-bladder to the wound on a level with the umbilicus, the liver having in the meanwhile receded sufficiently to allow of this higher approximation. The gall-bladder was opened and was found to contain a large number of gall-stones; these were removed, 76 in number. Mr. Collier endeavoured to introduce a long bullet probe into the common duct, and in doing so came across apparently no obstruction. The finger was next introduced and the whole of the tissues in the region of the middle portion of the duodenum were explored, but no stone or cause for the obstruction was ascertained. The wound having previously been closed, a fair-sized drainage tube was inserted into the opening in the gall-bladder, and the patient returned to bed. Mr. Collier said that this case was apparently one of simple obstruction of the gall-bladder by the impaction of gall-stones. The history, the absence of pain, the short duration and suddenness of the illness, all, he thought, pointed in this direction. Enormous distension of the liver and gall-bladder was, he considered, consistent with a sudden complete obstruction of the common duct. The up to this excellent health of the patient and her freedom from pain negated, he remarked, the suggestion of obstruction from malignant disease. The removal of 76 gall stones to some extent, he thought, bore out the diagnosis, but the fact that no stone had been found impacted in the common duct left a doubt in his mind as to the correctness of the diagnosis; on this ground Mr. Collier decided not to close the gall-bladder, and drop it in the peritoneal cavity, as by doing so the patient might have been left in exactly the same position as before the operation. By sewing the gall-bladder to the abdominal wound the patient, he pointed out, though not left in so satisfactory a condition as if the gall-bladder had been dropped into the peritoneal cavity, would be, so far as the distension of the gall-bladder was concerned, relieved of this and have a better chance of getting rid of the obstruction, whatever it might be.

The subsequent history of the case bore out entirely Mr. Collier's fears and anticipations. For the first ten days pints of bile continued to pour from the opening; the jaundice was not in the least relieved, nor did bile appear in the motions. The tube was removed and the opening allowed somewhat to contract; at the same time some pressure was exercised on it to induce if possible the bile to take its normal route into the intestine. This procedure was not followed by success, and no bile appeared in the motions. The patient steadily lost ground, all appetite ceased, and vomiting supervened; so there is but little doubt that some other cause exists for the obstructed common duct than a gall stone. Mr. Collier therefore proposes as soon as possible to have the patient anaesthetised and endeavour to make out the real cause of the obstruction.

WEDNESDAY, JULY 12, 1905.

THE REPORT OF THE IMPERIAL CANCER RESEARCH FUND.

THE Report of the Imperial Cancer Research Fund comes at an opportune moment. The times are agog with curiosity as to the innermost secrets of disease, and that too in the street no less than in the laboratory and the lecture-room. Recently London has been invaded by a Parisian surgeon with a much-boomed "cure" for cancer. Although his claims have been before the scientific world for some time they have not hitherto received any but scant and hesitating acceptance. That fact alone would make any experienced medical man extremely chary in sanctioning the trial of so dubious a method. When, however, we find it imported into London and its alleged virtues advertised to the world in six or eight different languages, a flavour of commercialism is added to the matter which is both nauseous and degrading. British surgeons, we are happy to believe, are competent to treat sufferers from cancer by all approved methods with as much confidence and success as can be hoped for in the present stage of scientific knowledge. It is hardly to be imagined that under any conceivable circumstance one of our countrymen would seek to establish a kind of branch practice in Paris for the exploitation of a vague, theoretical, and absolutely nebulous "cure" of an incurable disease. The attitude of the British scientific medical world can be well gauged from the Report to which allusion has been already made. The recent work of the Research Committee has been directed to the logical essential of the discovery of elementary facts of causation. The part of the Report to which medical men interested in the subject will at once turn is that which describes certain biological and pathological investigations under the heading of "The growth of cancer

under natural and experimental conditions." The results obtained by studying the disease in this way modify previous views to a considerable extent, while at the same time they control immediate inferences. "Cancer has been shown," runs one passage in the Report, "to be an identical process in all vertebrates, and to develop at a time which conforms in a striking manner to the limits imposed by the long or short compass of life in different animals. Cancerous tissue can be artificially propagated in the short-lived mouse by actual transference to another individual, but only to one of the same species, notwithstanding the histological identity in the nature of the disease in different species." Cancerous tissue thus propagated presents all the characteristic features of the malignant growth of sporadic humours; to wit, it infiltrates and produces extensive secondary growths. It is to be noted that experimental methods do not bear directly on the origin of cancer, although they throw a flood of light upon other aspects of malignant new growths. The most extraordinary fact of the experimental comparative growth is the continuous proliferation of the transplanted cells, which give rise to an undefined, enormous, and apparently limitless neoplasm. Under artificial propagation cancer maintains all the characters of the original tumours of the primary hosts. The statement of the Report is that the balance of evidence appears to be in favour of this enormous limitless growth being a cyclical form of proliferation, which is frequently renewed, and that in the first instance it is added to the terminal phases of normal proliferation in different tissues. Many important and often obscure special problems are discussed in the Report. The discrepancy between the recorded cancer death-rate in Ireland and in Great Britain is fully entered into, with the general conclusion that the discrepancy is apparent rather than real. An important point is raised by the specimens of malignant new growths obtained through the Colonial Office from the natives of regions of Africa where cancer had not previously been discovered. Going back for the moment to the artificial propagation, we find that it establishes the fact that transmission is fundamentally different from all known processes of infection. The whole Report furnishes an immense amount of valuable material accurately collected and collated. It is a scientific document of the highest value, worthy of the humane spirit that prompted the organisation of the Fund, no less than of the patience and insight and self-effacement that characterises the highest efforts of modern scientific medicine. In its simplicity, its dignity, and its absolute candour it offers a striking rebuke to the seeking after notoriety and worldly gain that fix on certain atter-day scientists a brand of indelible reproach.

JAPANESE LESSONS.

THERE can be no need for apology if we refer again to some of the many lessons that Japan is teaching Europe, nor will there be, till it is plain

that those lessons are being seriously laid to heart. Japan at the moment represents the spirit of modernity incarnated in a nation; a nation, moreover, which has definitely shaken off from the past everything but the driving power derivable from an intense sense of corporate duty. A nation thus equipped will be satisfied with nothing short of the best, and whether it be in war, administration, or science, Japan has not fallen short of the ideals its lynx-eyed statesmen of the seventies set before the people. The best-conceived plans may fail through over-reaching, unless they be carried out not only by a single-minded executive, but with a minute and painstaking attention to detail. Served as Japan has been by a galaxy of individual talent such as is only produced at times of national renaissance, the success that has so far attended her efforts has been due in a peculiar degree to the practical realisation of the value of initiative. The more that the present state of Japan is looked into, the more striking does this fact appear. The medical profession naturally turns to the condition of scientific and medical matters in seeking to assess the achievements and prospects of a country, and in no respect could a happier choice be made in the formation of an estimate of the Japan of to-day. In the elementary schools the natural sciences are depended upon as the instrument of mental training, so that every lad and girl in the country grows up with a mind trained to observe and reflect and possesses in addition a more or less intimate acquaintance with, and respect for, natural phenomena as guides to action. This scientific habit of mind is of priceless value in the cultivation of self-reliance and sound judgment, and it is a boon that Huxley was never tired of advocating as the birthright of every modern English child. As that great educationalist consistently maintained, natural science is natural knowledge, and as such should be placed before all academic acquisitions in an educational programme, after the three means of obtaining knowledge—reading, writing, and cyphering—have been acquired. To the fostering of this spirit among its young citizens may be attributed that thirst for information which characterises young Japan to-day. As a significant illustration of this spirit one may mention the formation among the students at Tokio of an association for speaking English, whose first meeting, attended by two hundred and thirty members, took place on May 13th. Papers, principally on elementary physiological subjects, formed the first part of its programme, and an address by Dr. Seaman, an American Army surgeon, the second. In this address Dr. Seaman mentioned that the spectacle of a body of students, voluntarily devoting their time to the acquisition of a foreign language, different in every respect from their own, illustrated more forcibly than anything else the determination of the rising generation to keep themselves *au courant* with the developments of their

science in other countries than their own, and that already some of the speakers, first and second year students, had attained remarkable facility. Dr. Seaman himself had come from America to learn on behalf of his department how it was that, when the United States in their war with Spain lost fourteen men from disease to each one from wounds, England in the Crimea six men from disease to one from wounds, France in Madagascar more than two hundred of disease to one from wounds, and England in South Africa an even larger proportion than the United States in the Civil War—how it was that Japan in her Titanic conflict with Russia managed to keep the medical wards in her base hospitals practically empty. That the latter was the fact he had witnessed with his own eyes, and he attributed it to the care in minute organisation which was expended on the army for ten years before it was sent into the field. Reflections are kindled by words such as these addressed by an American to a Japanese audience, reflections that are by no means favourable to the conduct of the army medical officers of this country. Changes there have been, many of them for the better, but we still fail to see any sign that the proportions of the problem of keeping the British Army free from disease are grasped by the War Office and military authorities. The matter is one of fundamental and vital importance to the very existence of the Empire, especially in view of the smallness of our Army in the absence of conscription. The efficiency of our Army alone can form a sufficient excuse for its size, and preservation of its health and the conservation of its energy are factors which lie, or should lie, largely in the hands of the Army Medical Department. Till that fact is realised, tinkering with battalions, army corps, and volunteers may go on indefinitely without the slightest rise in the efficiency of the Army as a whole. A pleasing token of the esteem in which the medical men in the public services of Japan are held, was given by the Emperor, when he recently raised Professor Takaki, lately Surgeon-General of the Japanese Navy, to the rank of Baron, an event which caused much public rejoicing. Takaki's name is known throughout the world as the man who banished beri-beri from the Japanese Navy. His theory that kak-he is due to deficiency in nitrogen in the sailor's ration is not generally accepted by tropical pathologists, but by a revision of the diet scale he caused the annual invaliding from the disease in the Navy to fall from one-third of the total force to less than a sixtieth—a fact which it is difficult to explain on other grounds than those he adduced. Such are the men that Japan delighteth to honour.

Notes on Current Topics.

Tropical Light and White Men.

THE increase of America's foreign interests, consequent on her occupation of the Philippines, has given an impetus to the study of tropical hygiene and medicine in the States. An

interesting contribution to this study has been made by Major Woodruff, Surgeon of the United States Army, on the effects of tropical light on white men. The darker pigmentation of the skin noted in tropical and sub-tropical races has usually been explained as due to the greater heat to which they are subjected. It is not obvious, however, in what way darkness of skin could be related either causally or by natural adaptation to excessive heat. Woodruff argues strongly in favour of the hypothesis that it is as a protection against light rather than against heat that pigmentation of the skin has been evolved. While a certain degree of light is, both in animals and plants, highly helpful to the processes of life, an excess is directly hurtful. In particular, it has been shown that the short rays are deleterious to metabolism. Woodruff believes, therefore, that it is necessary for white men to take certain precautions against the effects of light when they have to live in the tropics, and he makes some useful suggestions. The clothes worn during exposure to sunlight should be impervious to the short rays, and for this purpose black or yellow underclothing is best. At the same time, the outer garment should be such as will reflect the sun's rays as much as possible, white or yellow being suitable colours. The hat should be wide and thick, and lined with tin-foil, and an umbrella should be carried. During the brighter hours of the day, one should stay under cover as much as possible. Tents should be avoided altogether, wooden shelters being used when houses are unavailable. It is interesting to note that the medical officers of the American army are thoroughly alive to the problems waiting them in their duties in the tropics.

Early Specialisation.

THE degree to which specialisation is carried in medicine is often the subject of caustic remark on the part of the older generation, but so far in this country it has been held that all practitioners of separate branches of medical work should—if one excludes dentists—pass through the same course of general medical study before beginning to concentrate their energies on any particular branch. It has been left to the Harvard Medical School to introduce some variation in this salutary rule. With the opening of the academic year on May 1st an arrangement came into force by which students in their fourth year of study could make an unlimited choice of the subjects to which they would devote their attention, certain groups of subjects being suggested as presenting advantageous combinations under certain circumstances. Roughly, it would seem the aim of the promoters of the scheme was to train two separate classes of workers—those who would become clinical practitioners, and those who would give themselves to scientific work in laboratories. We are glad to hear that the large bulk of the students determine to take up clinical training, the numbers of those who aimed at laboratory work being small.

It is always a misfortune when any choice between clinical and pathological work takes place, for that physician who is not a fair pathologist is no physician, and that pathologist who is not a physician is, at the best, an incomplete pathologist. To import the distinction between medicine and pathology into the students' curriculum is early to foster a distinction which can never be anything but regrettable, and it may be trusted that many of the Harvard students who chose medicine will, eventually, from force of circumstances or taste, find their way to the laboratories in future life. They will at least have a better appreciation of the significance of the problems they are called on to solve than if they have specialised in pathology before being thoroughly *au fait* with the manifestations of disease in the wards.

"Maternity" and Cancer.

PROFESSOR CHIENE, of Edinburgh, in a recent address (a) quotes Mr. Balfour as saying that the natural sciences are, as time goes on, leaning more and more on idealism. This, perhaps, may suggest to some extent the psychical attitude of Professor Chiene himself in the address to which we refer. He has, in fact, put forward a theory of the causation of cancer, which, even if there be no new thing under the sun, has at least at the present day the appearance of novelty. Every cell has, like every animal, two varieties of reproductive activity, the maternal and the paternal elements. The excess of the paternal in the male is maintained through the exercise by the testicle of its hidden function, while the ovary similarly maintains the preponderance of the material in the female. In case the balance is not even, it can be restored by adding to the one or the other element. Now the growth of a malignant tumour is "early uncontrolled maternity; the cells divide when unformed and undeveloped; they reproduce their like when in their childhood. Why? Because of their excessive reproductive power, their excess of maternity." This being so, all that is needed to check malignant growth is to restore the balance by increasing the paternal element. Consequently, Professor Chiene is dosing his cancer patients with "didymin," an extract of rams' testicles. He also suggests the possibility of producing an "anti-maternal serum" by inoculating an animal with repeated doses of ovarian extract, this serum to be then administered to patients suffering from malignant disease.

Immigrant Legislation.

Now that the Aliens Bill is being run through Parliament with such energy as to ensure its eventually reaching the Statute Book this session, it is not too soon to prepare the mind for the consideration of those points on which medical advice will be sought. The best guide to knowledge of the subject is the experience of America, where alien legislation, as far as medical examina-

tion and exclusion are concerned, has been in force since 1891. Dr. Heiser, in the *Medical Record* of June 17th, states that the medical features of the immigrant legislation fall under two heads, namely, that for the exclusion of those suffering from affections for which exclusion is absolutely necessary, and, secondly, those suffering from conditions which may make them become a charge on the public. Each year it was found advisable to add to the schedule of diseases under both these heads, till in 1903 a fresh Bill was passed widening the act, far beyond the scope of its predecessor in 1891. Among the maladies which make exclusion absolute, trachoma is by far the most common, whilst favus ranks next in importance. Leprosy, active syphilis, and cases of tuberculosis with bacilli in the sputum are also included. While many people would be adverse to tubercle being made an absolute cause for exclusion in this country, it would be an unmixed gain if syphilis could be so far stretched as to prevent the dumping on these shores of prostitutes turned out of foreign brothels for venereal diseases. The American law goes far in its absolutely excludable list, for epileptics, idiots and the insane are all specifically mentioned. The class of those whose illnesses, though not infectious or undesirable in themselves, make their subjects liable to become a public charge, is a long one, and includes hernia, nervous affections, heart disease, malignant tumours, defective eyesight, senility, and many others. In case of temporary illness, persons arriving by steamer are treated in the public hospitals at the expense of the transportation companies; in other cases it is not difficult to bring the patient under one or other of the numerous heads which prohibit landing.

The Dread of Cats.

MOST of our readers have heard from time to time of people who are unable to bear the presence of cats in the room, or who suffer serious physical annoyance in their presence. Apart from the condition of cat asthma—asthma excited by the emanations from cats—a subject which has received detailed description from Dr. Byrom Bramwell and others, but little attention has been paid by scientific observers to antipathy to cats. Dr. Weir Mitchell, however, has recently collected material for the study of the question, and has made known the results of his inquiries. (a) He has satisfied himself without difficulty that there are many authentic cases of people who suffer from various curious symptoms as soon as they are aware of the presence of a cat. These symptoms vary from mere uneasiness or a "creepy feeling" to a state of absolute terror, causing a fear-paralysis or even convulsions. Vomiting is not uncommon. In all cases the symptoms disappear with the removal of the cat. In a few cases, Dr. Mitchell discovered that similar symptoms occurred in the presence of such animals as tigers

(a) *Edin. Med. Journ.* June, 1905.

(a) *American Med.*, May 27th, 1902.

and lions, though in most cases these animals were tolerated without annoyance. Apart, however, from cases where the sight of a cat was responsible for the sequence of peculiar symptoms, Dr. Mitchell found that there are many subjects who can tell the presence of a hidden cat. Some of these people recognise that they do so by an abnormally acute sense of smell, but most are unconscious of any such special sense impression. Dr. Mitchell thinks, however, that there is in all such cases an impression by the sense of smell, which, though itself remaining sub-conscious, may give rise to a train of symptoms which affect consciousness, and he brings serious analogical cases in support of the suggestion. It would appear that only people who suffer from the fear of cats—"allurophobia," as Dr. Mitchell terms it—have the power of detecting their presence while unseen. Of the cat fear itself he is unable to suggest any explanation.

Jewish Vital Statistics.

At the Royal Statistical Society recently, Mrs. S. Rosenbaum read an interesting paper on Jewish vital statistics. In London the Jewish birth-rate is estimated to be at the rate of 45 per 1,000 living as compared with 33½ in the case of London in 1903. The comparison being carried still further to allow for the difference in the proportion of married females at ages 15—45 among Jews and non-Jews, points rather to an appreciably greater fertility of Jewish women. The proportion of deaths under 1 per 1,000 births—generally known as the "infant mortality"—works out to 128 per 1,000. This is compared with the rate of 165 in the borough of Stepney, and 186 in the borough of Southwark during the years 1896 to 1900. The marriage-rate is estimated to be 19·2 persons married per 1,000 of the Jewish population, as compared with 17·4 only in the case of London. Allowance being made for the difference in the proportions of males and females aged 15 and upwards, it is shown that of those aged 15 and over, 1 in 35 males and 1 in 31 females are married annually among Jews; in London generally the proportions were 1 in 37 males and 1 in 44 females. The Jewish population of the United Kingdom is calculated to be just under 240,000 in the year 1903. Of this, 140,000 are in the London area, about 67,000 are in the rest of England and Wales, and about 25,000 in Scotland and Ireland. This population is increasing (1) by excess of births over deaths at the rate of about 5,000 per annum; (2) by immigration at the rate of 6,000 per annum. The following were the principal conclusions reached: 1. The death-rate from all causes and at all ages, except 0—5, is lower among the Jews than non-Jews in London. 2. The birth-rate is considerably higher. 3. The infant death-rate in proportion to number of births is very low. 4. The expectation of life at all ages for both sexes is higher. 5. The marriage-rate is higher. 6. The rate of natural

increase is higher. 7. The present Jewish population of the United Kingdom is about 250,000.

Physical Degeneration.

WE have always been warmly on the side of those enlightened and philosophic workers who, finding the physique of the nation not what it should be, are striving to bring about improvement by all reasonable agencies. At the same time, the "physical degeneration" cry has been carried too far in many quarters, as was shown by the report of the Departmental Committee on the subject, and we think it a pity that a good cause should suffer from bad advocacy. Things are sufficiently serious, but there is no need for exaggeration. If we turn our eyes to what is the case in other civilised countries, we shall find that the beef and beer of Britain still manage to raise a stock which compares not unfavourably with that of its neighbours. In New York forty-five inspectors were recently appointed to carry out investigations into the physical conditions of school children in the city, and 7,166 youngsters were examined by them. Of these 3,000, or nearly one-half, were pronounced to stand in need of medical treatment! A third of the children suffered from defective eyesight, and an almost equal number from bad teeth. The "underfed" numbered 632, and 650 were classified as having "bad mentality." A further examination showed that of the latter unsoundness of mind was due in most cases either to actual disease or to unhealthy surroundings. At any rate, the children were not fit for instruction in regular classes. All the school children are to be eventually examined with a view to determining whether they are likely to become victims of acute maladies—rather a difficult and delicate task, we should think—and whether their general health is good enough for them to be regularly enrolled in ordinary classes. Inspections such as these are probably more useful as testimonials to the advance of medical science in "spotting" deficiencies than as evidence of actual physical degeneration.

The Annual Election to the Council of the Royal College of Surgeons, England.

THE annual election to the Council of the Royal College of Surgeons, which took place on Thursday last, the 6th inst., was in certain respects unique. First, of the six candidates nominated for the four vacancies, one withdrew—Mr. Bruce-Clarke—two days after the list had been issued. We do not remember an incident of the kind occurring before; indeed, we believe that it establishes a record in the history of these elections. It was a magnanimous act on the part of Mr. Clarke to have withdrawn his candidature, inasmuch as had he gone to the poll probably a good many votes of the St. Bartholomew's School, which he represented, would have been diverted from his senior colleague, Mr. Cripps. As it was, practically the full strength of the supporters of St. Bartholomew's was available for Mr. Cripps, with the result that he was

one of the successful candidates. The other successful candidates were Mr. Edmund Owen and Mr. Godlee, who were re-elected, and Mr. Golding Bird. The only unsuccessful candidate was Mr. Andrew Clark, of the Middlesex Hospital. Here is another feature of the election: For the four vacancies there were virtually only five candidates—an absolutely unprecedented arrangement of the poll. While, however, this robbed the contest of most of its interest, at the same time it proved an exceedingly favourable occasion for the attainment of the ambition of those who competed. As we have before observed, the opportunity was a great one for the election of a Provincial Fellow; there can be no question that the Provincial Fellows have missed a splendid chance of adding to their already meagre representation on the Council. Under the circumstances a strong provincial candidate would have been almost certainly successful. College politics having reached a dead level, so far as the Fellows are concerned, the only element influencing the disposal of the suffrages was the personal one in this election. A great deal of canvassing was resorted to in the interests of the various candidates—not without effect, as the recorded result of the poll indicates; meanwhile there is only one detail more which can excite interest in the affairs of the College during the next twelve months, and that is the election of the President, which takes place at the first meeting of the Council succeeding the annual election.

A Crusade Against Cushions.

THERE is scarcely any custom of civilised life which does not come in for blame as a causative factor of disease. Thus we learn from a recent paper by Dr. Jerome D. Potts, of St. Louis (a) of the existence of a class of disorders called by him "Cushion Diseases," and due in his opinion to our preference of soft cushions to hard seats. Nature has provided us, Dr. Potts points out, with two bony prominences upholstered with tough, elastic cushions, with the design that we should sit upon them and not upon other parts. The consequence of scorning this wise provision of nature is that the neighbouring parts are, by our habit of sitting on cushions, subjected to pressure for which they are not adapted, with the result that these parts, being for long periods depleted of blood, suffer from deranged nutrition. At the same time, the increased local heat due to resting on a padded surface stimulates the secretion of the sebaceous and sweat glands, while escape of the secretion is prevented by pressure. In this combined interference with functions, Dr. Potts believes that an enormous variety of diseases has origin. Diseases of the skin and subcutaneous tissues, such as eczema, pruritus, and abscess; diseases of the mucous surfaces, such as urethritis, prostatitis, and anal ulcers; and diseases of the vessels and

(a) *Med. Record*, June 10th, 1905.

glands, such as piles, papillomata, and adenomata, are mentioned as the result of sitting on soft cushions. There is no doubt that Dr. Potts is right in pointing out that a hard seat has hygienic advantages over a soft one, but we fear he will have a hard task to persuade the world to carry his theories into practice.

Aerial Convection of Small-pox.

FOR many years, the question of the danger of a small-pox hospital to the population in its immediate neighbourhood has been under discussion. The general view at present is that the infection of small-pox may be carried by the air, and that consequently, apart from all defects of administration, a small-pox hospital constitutes a focus of disease for the neighbourhood. This view has been strongly supported by the case of the small-pox ships in the Thames, where disease spread to villages which had no communication whatever with the ships, and it only spread in the direction of the prevailing winds. The Local Government Board of England has, moreover, given this view official sanction by their regulation that a small-pox hospital must not have a population of six hundred within a radius of half a mile. All competent authorities have not, however, as yet given their adherence, and Dr. Claude Ker, from his experience at the Edinburgh City Hospital, is unable to find anything in support of the official view. (a) Within a quarter-mile radius of the Edinburgh Temporary Hospital at Colinton Mains there is a population of at least fifteen hundred, but in this district there was no excessive incidence of disease. Moreover, in the few cases that occurred it was possible to trace infection by ordinary means. Even among the inmates of the fever hospital within a hundred yards of the small-pox wards no case occurred. Dr. Ker is inclined to think that more careful administrative measures are responsible for the success of the isolation at Colinton Mains, and he has at any rate put forward a strong case against the aerial convection theory.

Whiskers.

DEMOCRACY and liberty are not always interchangeable terms, and the voice of the people may sometimes be as imperative and as autocratic as that of the deity with which it likes to be associated. At least, so we should judge from reading the regulations made from time to time by the health authorities in America. Far be it from us to decry any properly-directed energy in the regulation and preservation of the public health, but if we may believe a statement made in *Medical Notes and Queries*, the State Medical Board of Iowa, U.S.A., have gone the length of prohibiting the doctors in this State from wearing whiskers. The writer of the note, Dr. Willard Watson, attributes the order to the habit of the Western doctor of wearing his whiskers long, whereby countless hordes of bacteria are carried about on the

(a) *Edin. Med. Journal*, June, 1905.

doctor's person. The "expert" who was employed by the State Board to make the investigations found microbes so large that it did not need a microscope to see them, and the Board was led to believe that the objects discovered by the "expert" must be the bacilli and bacteria of which they had long read but never hitherto seen. However, the fiat has gone forth, and the razor is to sweep the chin of the Iowa doctor who prefers continuous practice to losing his hirsute adornments. Dr. Watson humorously demands information from the State Board as to the destination of the whiskers, and bids the Board take care they are not used for stuffing cushions and mattresses until they have been disinfected from the "microbes." It would be interesting to learn what idea the term "disinfect" would convey to the State Board; perhaps they would regard it as "something lingering, with boiling oil in it."

The West London Hospital.

THE acceptance of the Chairmanship of the West London Hospital by His Grace the Duke of Abercorn, K.G., has been cordially welcomed by the friends and supporters of that Institution. There is every reason for believing that under this new régime the prosperity of the Hospital will be still further increased. Funds have been recently raised for re-organising and rebuilding the casualty department—a much-needed improvement, and the work is on the point of being commenced.

Cancer Research.

ALL medical men will feel peculiar pleasure in the fact that the Prince of Wales continues to manifest the philanthropy that has always distinguished the members of the Royal Family, not only by his interest in the King Edward VII. Hospital Fund, but in the less showy but deeply practical matter of scientific research in pathology. This sympathy was evidenced by the holding of the third annual meeting of the Imperial Cancer Research Fund at Marlborough House, the Prince of Wales himself taking the chair. Nor is the interest of his Royal Highness merely a platonic one, for the Prince showed in the speech which he made at the end of the proceedings that he was well aware of the methods of the workers and of the value of their discoveries. Sir William Church gave an account of the year's work, and if many of the results that he had to announce were merely negative, at any rate the workers will be to a great extent disembarassed of many difficulties in the way of their research by having a comparatively free path in front of them. Cancer, they found, was not associated with any particular diet, climate or mode of life, and, as the Prince of Wales informed the meeting, none of the many reputed remedies sent from all parts of the world for investigation have proved of any real service. Any value they may have seemed to possess, said his Royal Highness, was based on a misapprehension of the meaning of the term "cancer." The well-known experiments with mice were referred

to, and it was pointed out how malignant growths could be propagated through several generations of mice, the cancer cells seeming to be endowed with the property of perpetual multiplication. No evidence of the infectivity of cancer was obtainable. The work of the Imperial Cancer Research Fund has so far been of high value, and we hope they will be encouraged by the past never to rest till they have solved the mysteries of the origin and cure of the disease.

Lady Somerset on a Drink Cure.

THE medical world may well stand agape at the spectacle of a clergyman of the Church of England laying down the law as to the medicinal action of a proprietary drug in so complicated a disease as alcoholism. Yet the Rev. Hugh B. Chapman, vicar of St. Luke's, Camberwell, does not hesitate to take upon himself the terrible responsibility of advocating a secret remedy sold under the name of "Normyl," as a certain and absolute cure for the drink habit. From his position in the Church the worthy clergyman in question is presumably an educated man, at any rate, so far as the externals of modern college education go. It is hard to imagine, however, that a man, if his mind were really trained in exact methods, would venture to settle professional problems which have hitherto escaped the vigilant advances of modern scientific medicine. Yet, lo! here is a simple-minded suburban vicar firmly persuaded that he has unloosed the Gordian knot which has baffled so completely medical men all the world over. We are glad to learn that Lady Somerset, a distinguished practical worker in the cause of temperance, has spoken out her strong disbelief in Mr. Chapman's pet discovery. In the *Westminster Gazette* of July 4th, she says that after many years of study of the drink problem she has seen drunkenness arise from so many causes that the assertion that a cure can be obtained from a drug sent out in bottles and administered to all alike seems to her absurd. Bravo for the logic of a courageous and distinguished woman! say we. By the way, the reverend gentleman must have saved the proprietors of the quack remedy an enormous sum in advertisement. Has he thought out the commercial aspects of his advocacy, we wonder?

PERSONAL.

THE Lord Mayor will give a dinner at the Mansion House, London, on Monday, the 31st instant, to celebrate the Tenth Session of the International Statistical Institute.

PROFESSOR KANEHIRO TAKAKI, Retired Surgeon-General of the Imperial Japanese Navy, Director of the Tokyo Charity Hospital Medical College, and Member of the House of Peers, has lately been raised to the rank of Baron by the Emperor of Japan.

DR. MATIGNON, a French doctor in the Japanese Red Cross Service, has invented a whistle, for the use of wounded soldiers on the battlefield, which, with but slight exertion, gives a loud sound, and which

may be used in place of the soldier's ordinary identification plate.

At the final congregations of the Cambridge term, held on June 20th, the honorary degree of LL.D., was conferred on the Right Hon. the Earl Cromer.

DR. JAMES RITCHIE, M.A., B.Sc., Fellow of New College, Oxford, Reader in Pathology, has been constituted Professor of Pathology so long as he holds the aforesaid Readership.

THE Gold Medal of Merit of the British Medical Association will this year be presented to Sir Constantine Holman, M.D., and to Mr. Andrew Clark, F.R.C.S.; and the Stewart Prize to Mr. W. Hy. Power, F.R.C.S., F.R.S., at the annual meeting of the Association, at Leicester, on the 25th instant.

DR. G. E. HERMAN, consulting obstetric physician to the London Hospital, has been elected an honorary member of the Gynæcological Society of Chicago.

LIEUTENANT-COLONEL L. E. ANDERSON, is appointed to the medical charge of the Cambridge Hospital, Aldershot, and to command No. 1 Company, vice Lieutenant-Colonel H. W. Hubbard.

FLEET-SURGEON FRANCIS AUSTEN JEANS has been promoted to the rank of Deputy Inspector-General of Hospitals and Fleets in His Majesty's Fleet.

At a meeting of the Council of the University of Birmingham held on Wednesday last, Professor Saundby, M.Sc., M.D., LL.D., F.R.C.P., was appointed Representative of the University on the General Medical Council of Education of the United Kingdom.

PROF. HERMAN NOTHNAGEL, the renowned scientist and physician, of Vienna University, died suddenly of apoplexy last week, aged sixty-five. His important discoveries concerning diseases of the brain and heart were made before he attained world-wide fame as a clinical teacher and humanitarian.

MISS EVA C. E. LUCKES, matron of the London Hospital, has been presented by the medical and surgical staff with a silver tea and coffee service, "in recognition of the completion of the twenty-fifth year of her matronship, and as a memento of the staff's appreciation of the great work performed by her in raising the standard of nursing to its present high state of efficiency."

CONSIDERABLE stir has been caused in medical circles in Germany by the resignation of Professor Schweninger from active work. This well-known medical man first became famous as Prince Bismarck's body physician and confidential friend. He filled in recent years the position of director of the large hospital at Gross Lichterfelde, near Berlin.

ON the 3rd inst., Sir Alfred L. Jones entertained a number of gentlemen at dinner at the Palatine Club, Liverpool, to inaugurate a new movement under the title of the Liverpool Tropical Research Institute.

H.R.H. THE DUKE OF CONNAUGHT last Saturday inspected the London companies of the Royal Army Medical Corps at Knightsbridge Barracks.

YESTERDAY, Tuesday, July 11th, before the Society for the Study of Inebriety, at its meeting in the Rooms of the Medical Society of London, Dr. Thomas Claye Shaw, opened a discussion on "The Psychology of the Inebriate." An abstract of Dr. Claye Shaw's paper appears in our present number.

Special Correspondence.

[FROM OUR OWN CORRESPONDENT.]

SCOTLAND.

EDINBURGH ROYAL INFIRMARY RESIDENTS' CLUB.—The eleventh annual dinner of this club took place on June 30th, the occasion being rendered especially interesting by the presentation to Dr. Claude B. Ker, the late secretary, of a handsome silver salver, on the occasion of his marriage. Dr. Claude Ker was one of, if not *the* originator of the Club, which has, during its eleven years of existence, proved an immense success in keeping the seniors and juniors of the profession in touch with one another. Professor Annandale, the President, in a humorous speech narrated several anecdotes of his old residency days, and in handing over to Dr. Ker the salver, wished him "as many joys of prospect and retrospect in the new residency he was about to enter as in that residency whose happy memories he had done so much to perpetuate." Among other officials of the club is one known as the "custos vestigiorum," and into his keeping was handed by Mr. Cotterill a ladle which had been used by the late Mr. Porter for thirty years for doling out soup to the patients.

TRACHOMA AMONG ALIENS IN GLASGOW has excited the watchful interest of the sanitary authorities, and Dr. Chalmers has just issued a report on the prevalence of the disease. As is known, candidates for emigration to America are required to submit to examination for trachoma, and a not inconsiderable number are rejected on account of the disease. The cases are divided into four groups:—(1) Those who arrive at Glasgow simply as a stage on their journey; of these ten a month are rejected. (2) Those who book to Glasgow, and immediately again book from Glasgow to America; of these five a month are rejected. (3) City emigrants, who after working in Glasgow wish to emigrate; of these only one a month is rejected. (4) County emigrants, who have laboured in Lanarkshire for variable periods, and then desire to go to America; these supply the largest number of rejections—23 a month. These figures point to the disease being most prevalent among aliens who have resided in Scotland for some time, and are against the view that trachoma is present chiefly in transmigrants. Of rejected candidates, about a quarter remain in Great Britain, and three quarters return to their homes. The United States authorities have found it needful to take steps to prevent the importation of the disease, and it seems highly desirable that some enactment should exist in this country to prevent the introduction of a malady which is as alien to the population as the sufferers themselves are.

Correspondence.

THE USE OF PESSARIES UNDER DIFFICULTIES. *To the Editor of the MEDICAL PRESS AND CIRCULAR.*

SIR,—I must express my thanks to Dr. Duke for the notice he takes of my communication on the above-named subject, and the generally favourable opinion he expresses of it. He has, as is well known, a mechanical bias, and I can well understand how it is that he uses pessaries with success. In teaching a patient to take out, clean, and re-insert a pessary I do not go quite so far as Dr. Duke assumes. I do not ask the patient, or expect her, to "replace the uterus." I only teach her to replace the pessary. If the pessary has done its work the uterus will not become displaced again the moment the instrument is withdrawn, but only after rising in the morning. As a matter of fact, the cases in which I have trusted the removal of pessaries to the patient themselves have generally been those of prolapse with slight backward displacement.

As regards the horizontal position, I simply mean that, quite regardless of whether it is the lateral

horizontal or the prone or supine horizontal. I only desire to get the column of blood level and the downward pressure of the abdominal viscera taken off the internal genitals. Perhaps in theory the prone position would be the best for cases of retroversion, as there the position would help the uterus forwards.

As regards his denial of my "sweeping statement," "that no man will be successful in these cases without first putting his patient to bed," my paper distinctly excluded the cases that could be so easily treated in the consulting room and at the first visit, and did not apply to them at all. That Dr. Duke would succeed, however, when the majority of practitioners would fail, I have not the least doubt, and I should say the same of any man who was possessed of knack and was not discouraged at a first failure, for here as elsewhere, "where there's a will there's a way." There is truth, no doubt, in what Emmett says about necessity for "decided mechanical talent" in the proper fitting of pessaries, but I am suspicious that it is not so much the talent that is wanting as the will to put it to a good use, which—and I think Dr. Duke will agree with me in this—is a great pity.

I am, Sir, yours truly,

J. E. BURTON,

Liverpool, July 10th, 1905.

THE DISCOVERER OF THE CIRCULATION OF THE BLOOD.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Those who are interested in such a question as you deal with in your article "Discoverer of the Circulation of the Blood" may get some idea of what the views of the profession were in this country by carefully looking through the works of Thomas Sydenham, M.D. Sydenham and Harvey were contemporaries; the one a great physician, the other a great anatomist. There is not the least doubt but that the greatest ignorance prevailed of how the circulation of the blood was carried on. It was how to disperse those clouds of ignorance and error that Harvey had chiefly to think of and work out. The establishment of a New Law or Principle is very different from the discovery of a new fact. Harvey spent far more time and thought on the anatomy of the ovum than on that of the heart. Those who care to look into the value of Harvey's work would do well to read carefully Froude's Essay on "England's Forgotten Worthies."

"It is almost impossible to throw back our imagination into the time when, as new grand discoveries, they stirred every mind which they touched with awe and wonder at the revelation which God had "sent down among mankind," and "strangely failing to see that the real value of the actions or the thoughts of remarkable men does not lie in the material result which can be gathered from them, but in the heart and soul of the actors or speakers themselves."

I am, Sir, yours truly,

R. L.

July 7th, 1905.

Obituary.

Dr. ROBERTS DUDLEY, J.P.

We regret to announce that last week Dr. F. J. Roberts Dudley, J.P., the medical officer of health to the Stalybridge Corporation, was found dead in bed. The cause of death was angina pectoris. The doctor had been ill for twelve months or more, but he was out on Saturday as usual attending to his professional duties. He was the oldest magistrate on the borough bench, his name having been placed on the commission in 1874. He was medical officer of the borough for thirty-two years, vaccination officer for the district, and medical inspector under the Factories Acts. A Rochdale man by birth, he came into the Stalybridge district some forty-five years ago. He was 64 years of age.

Literary Notes and Gossip.

Le Radium is the name of a new monthly journal devoted to radio-activity and radiations, and the sciences related thereto. The Editorial Committee comprises MM. d'Arsonval, Becquerel, Bécclere, R. Blondlot, Ch. Bouchard, P. Curie, Danysz, Debierne, Ch. Féry, Ch. E. Guillaume, Oudin, Rubens, and Rutherford.

It is frequently said that the British, more especially the professional classes, are very small book-buyers. In this connection it may be of interest to hear that one of the numerous medical publishing houses in London, Messrs. Bailliere, Tindall and Cox, have put on the market the enormous total of 105,325 copies of books and pamphlets during 1904 in spite of the generally recognised fact that that year was the worst on record in the publishing trade.

EDINBURGH lies *en route* to so many summer homes and autumnal rambles that many of our readers will be pleased to know of some recent and discursive information about this most interesting of our northern cities. Such would enjoy the pleasant-reading "Auld Reekie" article in *Blackwood's Magazine* for July. It is just adapted for reading in a train, or an evening at an hotel. Full of information, literary and archaeological, yet in no way pedantic or prosaic. In all respects it is worthy of *Mega's* best days.

SIR T. McCALL ANDERSON'S "Plea for the More General Use of Tuberculin" cannot fail to attract attention at a time when the therapeutical applications of these preparations are being laboriously worked out. This particular "plea" having been delivered before the Dermatological Society, the author has confined his remarks to forms of tuberculosis associated with cutaneous manifestations, but the results that he has obtained stimulate one's desire to study the employment of the tuberculin in the more recondite forms—visceral and osseous tuberculosis, for example. It is extremely interesting to find that tuberculin injections have proved markedly beneficial in a case of Addison's disease, especially as the clinical evidence points to a direct local effect on the suprarenal capsules preceding the improvement. We are familiar with the remarkable curative action of tuberculin in lupus and *cæteris paribus* the method of treatment is much simpler and cheaper than the popular light treatment. The brochure is liberally supplied with excellent illustrations of the effects of treatment in lupus of the face.

THE current number of *The British Journal of Inebriety* (the official organ of the Society for the Study of Inebriety), edited by Dr. T. N. Kelynack, contains an important article on the Medico-Legal Aspects of Alcoholism, by Dr. Stanley B. Atkinson, and a controversial essay on the hereditary influence of alcoholism, by Dr. Archdall Reid, together with other papers opportune and valuable.

SIR VICTOR HORSLEY'S Lecture on "The Effect of Alcohol upon the Human Brain" has recently been issued by the Lees and Raper Memorial Trustees, in convenient pamphlet form.

Medical News.

AN epidemic of typhoid fever has broken out in some quarters of Madrid.

Legacies for Dublin Hospitals.

MR. PATRICK BIRMINGHAM, of Kingstown, recently deceased, left by his will over ten thousand pounds for various charitable, religious, and educational objects. Among the bequests are £250 to the Hospice for the Dying, £250 to Jervis Street Hospital, £250 to the Holles Street Lying-in-Hospital, and £250 to St. Michael's Hospital, Kingstown.

Medical Sickness and Accident Society.

At the usual monthly meeting of the Medical Sickness, Annuity and Life Assurance Society held on the 30th ult., there were present the Chairman, Dr. de Havilland Hall, Dr. J. Brindley James, Dr. J. H. Dempster, Dr. Sinclair B. Shadwell, Dr. F. J. Allan, Dr. F. S. Palmer, Mr. F. S. Edwards, Dr. W. Knowsley Sibley, and Dr. J. B. Ball. The accounts presented showed the society to be progressing satisfactorily. The claims have lessened since the early spring and are now under the average expected from the Sickness Experience Tables, upon which the rates of contribution to the Society are based. The number of new entrants is also showing satisfactory growth. During the first half of the current year the number of new members is appreciably greater than in the corresponding period of 1904, and as the Society pays nothing for commission or advertisement this shows that the members are responding to the appeal of the Committee to bring the advantages offered by the Society under the notice of their professional friends. Prospectuses and all particulars of Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

Royal College of Surgeons.

A meeting of Fellows was held at the Royal College of Surgeons of England, on Thursday, for the election of four members of the Council. The result of the poll was as follows:—Mr. Edmund Owen (re-elected), of St. Mary's Hospital, 512 votes; Mr. Rickman J. Godlee (re-elected), of University College Hospital, 471 votes; Mr. C. H. Golding-Bird, of Guy's Hospital, 480 votes; and Mr. W. Harrison Cripps, of St. Bartholomew's Hospital, 373 votes. In the evening about 100 Fellows dined together at the College. Mr. John Tweedy, president, took the chair, and was supported by, among others, Mr. Thomas Bryant, Sir Thomas Smith, Mr. Reginald Harrison, Mr. John Langton, Mr. Mayo Robson, Mr. Henry T. Rutlin, Colonel Pilcher, Mr. John Poland, and Mr. Henry Colgate.

Royal College of Surgeons in Ireland.

The following prizes were awarded last week to students in the School of Surgery for the Summer Session, 1905:—

Barker Anatomical Prize—£26 5s., T. A. Burke; *Special Prize*, £21, J. B. Kelly.

Carmichael Scholarship—£15, R. M. Bronte.

Gold and Silver Medals in Operative Surgery—Gold—J. Prendiville; Silver—R. Bury and L. Lucas (equal).

Stoney Memorial Gold Medal in Anatomy—T. Sheehy.

Practical Histology—G. C. Sneyd, First Prize, £2, and Medal; E. Harrison, Second Prize, £1, and Certificate.

Practical Chemistry—Miss A. F. Nash, First Prize, £2, and Medal; T. A. Peel, Second Prize, £1, and Certificate.

Public Health and Forensic Medicine—C. J. B. Dunlop, First Prize, £2, and Medal; W. E. M. Hitchens, Second Prize, £1, and Certificate.

Materia Medica—C. J. B. Dunlop, First Prize, £2, and Medal; V. J. Clifford, Second Prize, £1, and Certificate.

Biology—E. A. Gregg, First Prize, £2, and Medal; E. Harrison, Second Prize, £1, and Certificate.

The next Preliminary Examination is fixed for Tuesday, September 26th. The School of Surgery will resume work on Monday, October 2nd.

Society of Apothecaries of London.

The following candidates passed in:—*Biology* (Primary Exam, Part 1)—U. J. Bourke, R. S. Minchin. *Chemistry*—H. S. Brown, R. J. W. McKane. *Materia Medica and Pharmacy*—W. E. Dimond, L. R. Nezet, P. D. Pickles, C. J. Wolfe. *Anatomy* (Primary Exam, Part 2.—L. G. H. Furber, W. J. Gibson, T. Huddleston, C. J. M. Lawrence, E. A. Mordaunt, G. F. Page, A. Perlman, P. A. Sullivan. *Physiology*—L. G. H. Furber, T. Huddleston, C. J. M. Lawrence, P. J. Lush, E. A. Mordaunt, G. F. Page, P. A. Sullivan.

University of Birmingham.

The following is a list of successful candidates in the Faculty of Medicine, June, 1905:—

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Frank Marsh; Class II.—Edward Lancelot Bunting, Leonard Leigh Hadley, William Claude Horton, William Cuthbert Houghton, Henry Percy Pickerill, Thomas Holmes Ravenhill, Norman John Lancelot Rollason, *Frederick Wilkinson.

Fourth Examination for the Degrees of M.B., Ch.B.—Class II.—*Herbert Charles Horace Bracey, Lionel Chattock Hayes, Arthur Cecil Hincks, Claude Johnson, Walter Rowland Southall Roberts.

Third Examination for the Degrees of M.B., Ch.B.—Class II.—Edward James Boome, Henry Neville Crows, *James Fenton, Eric Thomas Gaunt, John Kennedy Gaunt, Philip James Mason, Nevill Coghill Penrose, Arthur John Smith, Rupert Wesley Thompson, Francis Brett Young.

Second Examination for the Degrees of M.B., Ch.B.—Class II.—John Adams, Charlotte Bailey, *Mary Clarke, George Henry Chavasse Mold, John Lichtenstein Ritchie, Herbert Henry Sampson, Edward Vernon Whitby.

First Examination for the Degrees of M.B., Ch.B.—Class I.—Cranston Walker. Class II.—James Henry Bampton, Walter Charles Blackham, Norman Alexander Boswell, Charles William Hayward, Humphrey Francis Humphreys, Violet Maud McCready, Arthur Harry Newton, Kenneth Douglas Wilkinson, Harry Wilks.

Degree of Bachelor of Dental Surgery.—Reginald Hudson Astbury.

Degree of Bachelor of Science in Public Health.—Robert Arthur Lyster, Sydney Herbert Hawley, William Sisam. *Scholarship.

Trinity College, Dublin.

List of candidates who passed the final examination, Section B., at Trinity Term, 1905:—Francis R. Copping, John D. Sands, Thomas H. Peyton, Richard A. Connell, John C. P. Beatty and Edward Gibbon (equal), W. Gustav Thompson, Basil G. Brooke and Robert B. Jackson (equal), Samuel G. S. Haughton, Thomas J. Cobbe, William I. Thompson, Henry D. Drennan, Alfred C. Elliott, Percy B. Egan, Ernest C. Phelan, Herbert J. Wright, Theodore C. Somerville, Dudley F. Torrens, Malcolm K. Acheson, Daniel M. Corbett, Thomas L. deCourcey, Herbert R. R. Fowler.

The Royal University of Ireland.

The following candidates have passed the First Examination in Medicine:—Joseph Anderson, William J. Ashby, James S. Bellas, Francis Bradley, Percy M. J. Brett, James A. Brown, Bartley Byrne, Samuel Campbell, Samuel R. Campbell, Francis S. Carson, Albert V. Craig, Albert T. Crowley, Patrick J. Cullinan, William Dickey, Ernest S. Dixon, William Doolin, Francis Harold Duke, Francis P. Ferran, B.A.; David J. Foley, William A. Frost, John J. Gilmore, James A. Hanrahan, John H. Harbison, Arthur V. J. Harrison, Patrick Hayes, Richard W. G. Hingston, Jeremiah Holland, David Horgan, John C. Houston, David J. Jackson, Edward G. Kennedy, Ernest W. Kirwan, Bertram C. Letts, Denis Lynch, James McCormick, Barkley McCullough, B.A.; George E. A. Mitchell, Eileen M. O'Keefe, James M. O'Reilly, Charles Ronayne, Peter J. Ryan, Thomas Scanlan, John Spence, Alfred M. Thomson, Michael Twohio, John F. Walsh, William O. Wilson, Robert Young. The following candidates have qualified upon their answering to present themselves for further examination for Honours in the subjects set after their names. Those qualified in two or more subjects may present themselves for the further examination in all subjects:—Joseph Anderson, Botany; William J. Ashby, Physics; James S. Bellas, Botany; James A. Brown, Physics; Samuel Campbell, Botany and Chemistry; Samuel R. Campbell, Chemistry and Physics; Francis S. Carson, Botany; Albert V. Craig, Chemistry; William Dickey, Botany and Zoology; Francis P. Ferran, B.A., Botany, Zoology, Chemistry, and Physics.

Notices to Correspondents, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

CORONER.—Distension of the lungs in drowned persons is taken as a sign of life when they entered the water. Margulies believes the shock of the cold water causes a deep inspiration, which air cannot be expelled if complete submersion takes place.

DR. F. (Nigeria).—The effect of anti-propagation measures against mosquitoes must always be a reduction of the mosquito density, not only within the area of operation, but to a distance equal to the ideal limit of migration beyond it.

L. S. A.—The Scotch and Irish Schools commence the Winter Sessions rather later than the English ones. Full particulars are given in our September Students Number.

DR. H.—Embalming in London is practised more than you suppose. The Anglo-American Embalming Company in Tottenham Court Road, London, W., publish a small paper on the subject.

DR. ALICE F. (Dublin).—The first lady doctor in Hungary was Miss Charlotte Steinberger. You should advise your friend to seek one of the many medical posts under the L.C.C. They are well paid.

SURGEON (Derby).—Dr. Alexander Duke claims to be the first to suggest the "hot-water operating table."

M. O. H. (Rutland).—In 1904, in Persia alone, 70,000 persons died of cholera. Europe is assailable by four ways: by Moscow, St. Petersburg, and the Baltic Ports, by Odessa, and the Black Sea route, and Constantinople.

THE MEDICAL ACT AMENDMENT BILL.

B. (Manchester).—The Medical Act (1886) Amendment Bill passed its second reading in the House of Commons on Friday last, so that there is the chance of its escaping the "slaughter of the innocents" this year.

ONE INTERESTED.—The subject is under consideration, but it is one beset with so many difficulties, that time only can solve. Your suggestions, however, are useful, and we tender our thanks for them.

FOURTH YEAR'S STUDENT.—The advice given you as to the two manuals of "Medicine" and "Surgery" cannot be improved upon.

M. A. D.—The gentleman to whom you refer has retired from practice.

T. A. S. P.—The matter will receive our attention in an early issue.

M. E. D.—No.

YEDDO.—The incident has not come under our notice.

H. S.—Your letter is unavoidably crowded out.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JULY 12th.

THERAPEUTICAL SOCIETY (Royal Botanic Society's Gardens, Regent's Park).—Garden Meeting to view the Medicinal and Other Plants.

DERMATOLOGICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—5.15 p.m. Meeting.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Mr. J. Berry: Clinique. (Surgical.) 5.15 p.m. Dr. J. Fawcett: Cancer of the Stomach.

THURSDAY, JULY 13th.

BRITISH GYNECOLOGICAL SOCIETY (20 Hanover Square, W.).—8 p.m. Dr. C. Maunsell: (1) A Case of Endothelioma Uteri, illustrated by drawings and microphotographs. (2) An Improved Method of Ventrofixation of the Uterus, illustrated. Dr. H. Macnaughton-Jones: (1) Note on Cyllin as a Post-operative Antiseptic. (2) Note on a Case of Post-operative Parotitis. (3) Note on a Case of Urethral Cyst.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m. Dr. D. Sommerville: Errors of Digestion in Relation to Disease.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (7 Fitzroy Square, W.).—5 p.m. Lecture:—Mr. H. Barwell: The Diagnosis of Tuberculous Laryngitis in its Early Stage. (Post-Graduate Course).

FRIDAY, JULY 14th.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Mr. H. W. Dodd: Clinique. (Eye.)

Vacancies.

Middlesex Hospital, London, W.—Lady Superintendent. Salary £150 per annum, with board and residence. Applications to F. Clare Melhado, Secretary Superintendent.

The Victoria University of Manchester.—Junior Demonstrator in Physiology. Salary £100 per annum. Applications to the Registrar.

The Hospital for Consumption and Diseases of the Chest, Brompton.—Resident Medical Officer. Salary £200 per annum, with board and residence. Applications to the Secretary.

Borough of Leicester—Education Committee.—Medical Officer. Salary £400 per annum. Applications to T. Groves, Secretary, Education Department, Town Hall, Leicester.

Dorset County Hospital, Dorchester.—House Surgeon. Salary £100 per annum. Applications to W. E. Groves Valetta, Icenway, Dorchester.

North Staffordshire Infirmary and Eye Hospital, Hartshill, Stoke-upon-Trent.—Senior House Surgeon. Salary £100 per annum, with furnished apartments, board, and washing. Applications to the Secretary and House Governor.

The Royal National Hospital for Consumption, Ventnor.—Senior Resident Medical Officer. Salary £200 per annum, with board and lodging in the Hospital. Applications to the Secretary, 34 Craven Street, Charing Cross, London.

Bradford Poor Law Union.—Resident Assistant Medical Officer. Salary £100 per annum, with rations, apartments, and washing. Applications to George M. Crowther, Clerk to the Guardians' Union Offices, 23 Manor Row, Bradford.

Appointments.

LEDINGHAM, J. C. G., M.A., B.Sc., M.B.Aberd., Assistant Bacteriologist to the Serum Department, Lister Institute, Elstree.

MORRIS, L. N. L.R.C.P.Lond., M.R.C.S., Assistant House Surgeon at the Bristol General Hospital.

OLIVER, W., L.R.C.P., L.R.C.S.Edin., Certifying Surgeon under the Factory and Workshop Act for the Coxhoe District of the county of Durham.

PATON, E. PERCY, M.D.Lond., Examiner in Anatomy to the Society of Apothecaries of London.

RICHARDSON, A. G., M.B., C.M.Edin., Certifying Surgeon under the Factory and Workshop Act for the Bhayader District of the county of Radnor.

RICHARDSON, A. W. CECIL, M.B.Lond., Casualty House Surgeon at the Bristol General Hospital.

RICHMOND, G. E., M.D., B.S., B.Sc.Lond., D.P.H.Cantab., the London County Council Resident Medical Officer to the Rotherhithe Tunnel Works.

SHEPPARD, A. L., M.B., Casualty Officer at the Bristol Royal Infirmary.

SHORT, ARTHUR RENDLE, M.D., B.S., B.Sc.Lond., House Physician to the Bristol General Hospital.

Births.

JONES.—On July 2nd, at Claybury, Woodford Bridge, Essex, the wife of Robert Jones, M.D., of a daughter.

MARTIN.—On July 2nd, at Netley, Hants, the wife of Major C. B. Martin, R.A.M.C., of a son.

Marriages.

BRADLEY-CADBURY.—On July 8th, at the Friends Meeting House, Birmingham, Neville Bradley, M.B., son of Frederic Bradley, Thornton Hall, Cheshire, to Margaret, fourth daughter of the late Richard Cadbury, J.P., Uffculme, Birmingham.

ROBINSON-SIRBALD.—On July 4th, at Dunga Gall, Murree Hills, India, Captain J. H. Robinson, R.A.M.C., eldest son of Edward Robinson, Esq., Paymaster-in-Chief, R.N. (retired), to Harriett Graham, fourth daughter of the late Sir John Sibbald, formerly one of H.M. Commissioners in Lunacy for Scotland.

WARREN-BUCHANAN-DUNLOP.—On July 8th, at Christ Church, Reading, Alfred Castle Warren, M.R.C.S., L.R.C.P., of 13 Campden Hill Square, London, son of the late William Warren, of Dibrugarh, Assam, to Sabina, (Ina), eldest daughter of Lieut.-Colonel H. D. Buchanan-Dunlop, R.A. (retired), of Whitley Rise, Reading.

Deaths.

ANDERSON.—On July 5th, at 9 Kerrison Road, Ealing, after a very brief illness, Fleet-Surgeon Robert William Anderson, R.N., aged 49.

CAMERON.—On July 5th, at Edinburgh, Robert W. D. Macmartin Cameron, M.D.Sc., late of Newton Stewart, N.B.

METCALFE.—On July 3rd, at Clifton Gardens, London, Edmund Metcalfe, F.R.C.S., in his 86th year.

SMITH.—On July 5th, at Orleans House, Regent's Park Road, London, Cyrus Walter Smith, L.R.C.P.Lond., M.R.C.S., the beloved and only surviving son of Walter Smith, M.D., M.R.C.P.Edin., and Susan Smith of above address, aged 32 years.

Original Communications.

IN DEFENCE OF THE PESSARY.

By GEO. GRANVILLE BANTOCK, M.D. EDIN.,
Consulting Surgeon to the Samaritan Free Hospital. (a)

Two papers have recently appeared on the subject of the use of the Pessary, the one entitled "On the Application of Pessaries and their Dangers;" (b) and the other "Pessaries: their Uses and Limitations." (c) Both of these contain statements which challenge criticism.

With regard to the *dangers* of the pessary it would be quite as much to the point to speak of the dangers of the scalpel. The dangers arising from the use of the pessary are due to ignorance, want of skill, or carelessness on the part of the practitioner, or to ignorance and carelessness on the part of the patient. The practitioner is either ignorant of the principles of its proper use, or deficient in skill in employing it, or careless as to the instructions he gives the patient; or the latter, being wholly ignorant of the subject, is careless in carrying out her instructions.

The authors of these papers seem to have brought together the *possibilities* of danger as a peg on which to hang a plea for surgical interference, but they are unable to produce any evidence in support of their argument. They are much taken up with "the pathological conditions (in the words of one of them) which contraindicate the use of any pessary, and where its presence constitutes a distinct danger." The use of a pessary under these circumstances must surely be regarded as an indication of gross incompetence.

With regard to their "uses and limitations," I am in accord with much of the argument of the writer, but when he speaks of them as a *necessary evil* I entirely disagree with him. If this be correct, then, any operation or method of instrumental treatment is a necessary evil—even the wearing of a set of false teeth. Now there are only four conditions affecting the uterus to which the use of a pessary is applicable. These are uncomplicated retroversion, antelexion, retroflexion, and prolapse. Perhaps I ought to include elongation of the cervix; but as it is usually associated with some prolapse of the whole organ it scarcely deserves to be erected into a separate class. The enumeration of the various pathological conditions that may be associated with these serves only to obscure the subject, for they, not the displacement, become the subject of our solicitude. But the examples of the *abuse* of the pessary enumerated by this author are quite to the point. When, however, he says that "properly fitting pessaries, rightly applied, have enough to answer for in the way of drawbacks and complications," I find another point for disagreement. It may seem trifling with the subject to ask the question, "What is a dis-

placement?" But it is not so, as a proper answer to this question is absolutely necessary. A displacement, properly so-called, is a departure of the uterus from its normal *position*. Hence there is in reality only one form of displacement, viz., retroversion. I am glad to find that there is a general acknowledgment that anteversion of the uterus is not a pathological condition *per se*. This is the position I took up nearly a quarter of a century ago, but it has not yet met with acceptance by the author of the first paper. The normal position of the uterus with regard to the axis of the vagina is one of anteversion, and to speak of anteversion as a displacement is obviously incorrect. Among writers on this subject generally—and this is characteristic of the two above referred to—no distinction is drawn between *retroversion* and *retroflexion*. Schultze, in one of his tables, groups these under the head of retroflexions, and in another brackets them. Now a retroversion means a *turning* backwards, and a retroflexion a *bending* backwards, of the organ. This is a distinction with a mighty difference, and ought to be kept clearly in view. No work with which I am acquainted, with the exception of that of Hart and Barbour, clearly observes this distinction. Others use the terms as being synonymous. Hence we find the greatest discrepancy as to their relative frequency. This is seen in a table of Schultze's in which he gives, under the head of retroflexion the experience of various authors, the frequency ranging from 12 to 198 "per 1,000 cases of diseases of women," from 200 to 297 "per 1,000 displacements," and from 84 to 550 "per 1,000 flexions."

Strange to say, the distinction between *anteversion* and *antelexion* seems to be observed. Of the first Klob says, "As a matter of course, anteversion cannot attain a very high degree." To this I may add that any exaggeration of this, which I call the normal condition will be due to a pathological state which then becomes the point for consideration. I do not know why so many gynaecologists of the day should persist in saying that antelexion is the normal form of the virgin uterus. It is not so described in "Quain's Anatomy," but is represented as being quite straight. No notice appears to have been taken of the special investigation of Bandl, who as the result of *post-mortem* examination of a large number of cases arrived at the following conclusions:—"In the new-born the uterus was partly straight, partly in slight antelexion, lying in the pelvic axis." "In older children, in whom the body of the uterus has acquired greater firmness, that organ is far more frequently found straight." "The straight form of the uterus is frequent as compared with the antelexed."

A great deal has been written about the causes of uterine displacement. I particularly refer to retroversion. I do not see how any knowledge of this kind can help us in the least in the matter of treatment. We are not called upon to prevent displacement, but to remedy it, except in the case of a patient who has been the subject of displacement previous to a pregnancy which had been brought about perhaps, or at least aided, by the application of a pessary—of

(a) Read before the Edinburgh Obstetrical Society.

(c) Arthur Giles, M.D. PRESS AND CIRC., Vol. CXXIX, 1904, page 1, etc.

which I have seen many examples. The surgeon is not aided in his treatment of a broken leg by a knowledge of the way in which the fracture has been sustained. The only opportunity for practising preventive treatment arises when the subject of a retroversion has become pregnant while wearing a pessary, or was known to have a retroversion at an early stage of pregnancy. In such a case the patient should not be allowed to lie on the back during the puerperium, and the earliest opportunity should be taken to ascertain the position of the uterus. Such a case has come under my notice while writing this paper. Some few years ago I found the patient to be the subject of a very bad laceration of the perineum, a large rectocele, a smaller cystocele and a well-marked retroversion. I restored the perineum with a view to a subsequent pregnancy, and applied an Albert Smith-Hodge's pessary, which gave immediate relief to very distressing symptoms. In January last, after the lapse of about seven years, and believing herself pregnant, she again consulted me, earnestly desiring that I should produce abortion because she was afraid she might have a repetition of her former trouble. I comforted her on this point, instructed her not to lie on her back after delivery, and wrote to her medical attendant. My instructions were rigidly carried out, and when she came to me at the end of three weeks I found the uterus in perfect position. My intention was to apply a pessary if the uterus showed any sign of becoming retroverted, for if taken at this early period a cure can be confidently anticipated. That a retroversion is sometimes caused by a fall on the buttocks, or even on the face is unquestionable—of both of these I have seen several examples—but I do not see how this knowledge affects the treatment. We may tell women that they must avoid falling in either of these ways, lifting heavy weights, or straining at stool. But probably in 999 cases out of a 1,000 this advice would be useless. Hence disquisitions on etiology appear to me to be labour lost.

A knowledge of the frequency of displacement, or malformation in the female population is obviously unattainable. But we can form an approximate idea of their comparative frequency. According to my experience the three states of retroversion, ante-flexion, and retroflexion stand in the order of frequency as I have named them. Retroversion with ante-flexion is so very rare that it may be regarded as a curiosity, and scarcely deserving of being erected into a separate class. I have seen but very few cases in an experience of forty years. Two of these are recorded in my little book on the "Use and Abuse of Pessaries," and as far as I know they were the first observed.

Now, given a case of uncomplicated retroversion, in which the uterus is perfectly mobile and capable of being raised into its normal position, either bimanually or by means of the sound I unhesitatingly assert that the only legitimate treatment is that by a properly adapted pessary. I protest against the statement of a well-known operator that "the only place for the pessary is the back of the fire." Such a statement can only be the outcome of profound ignorance of the subject. The mania for surgical interference which characterises the present-day gynaecology, the ignorance prevailing with regard to the principles of the treatment by the pessary, and the want of skill in its application, have blinded men to the justice of this simple proposition which I have laid down, and we read of hundreds of cases of operation by individual operators, such as shortening the round ligaments from without or from within the peritoneal cavity, ventro-fixation and vagino-fixation. If I could have brought my conscience to the point of persuading my patients to submit to any one of these operations, I also should have been able to reckon them by hundreds. But I have never done so. Alexander's operation never appealed to me because of the fact that when the uterus is pulled down the last structures put on the stretch are the round ligaments, while ventro-fixation placed the uterus in an unnatural position, and vagino-fixation appeared to

me an outrage on common sense. On the contrary, there is no branch of my work that gives me more satisfaction than the use of the pessary in cases of uncomplicated retroversion of the uterus, and for these reasons, viz.: the absolute *absence* of danger, the relief which it gives in all cases when properly applied, and the prospect of cure in a large majority of the cases. It is no valid argument against its use that the pessary has to be worn for many years. The same objection may be urged against the wearing of a set of artificial teeth, and with much more justice.

The time required to effect a cure will be in proportion to the duration of the displacement. Striking examples establishing this proposition are afforded by the cases of recent occurrence to which I have already referred, viz.: from falls, and in which relief was immediately obtained and a cure effected within a year, as well as in the following case very briefly related. A former patient of mine (1890) was cured of uterine congestion, and a year after the cessation of treatment bore her first child, after having been sterile for four years. After several years of widowhood she married again, and being desirous of having at least one child more, for her husband's sake, again sought my aid in January, 1896. The uterus was in perfect position and free from congestion, but the cervix was hard and the canal contracted. Under a course of treatment by graduated bougies the canal became patulous, and in due time she became pregnant. She had a very good confinement, but immediately on getting up she began to suffer great discomfort and even pain in the pelvic region. An appeal to her medical attendant was without avail, and as soon as she could travel she came to town. Examination revealed a well-marked retroversion. The application of a pessary gave her immediate relief, and in a year I removed it. Six months afterwards the uterus was in perfect position.

The majority of my patients come after many years of suffering, some—I may say most—of them having worn pessaries (up to as many as seven) of various kinds and sizes, others only subjected to medicinal treatment. I have a large number of pessaries duly labelled, as examples of completely successful treatment, *i.e.*, cure; but I have, or have had till recently, a very much larger number illustrating unsuccessful treatment, removed from patients to whom I have been able to afford relief. These examples illustrate the ignorance prevailing with regard to the principles of treatment. To say that a man who puts a pessary into a woman's vagina merely because she has symptoms referable to the pelvic region is ignorant of first principles is a self-evident proposition. And yet how many of these cases have I seen! Given a genuine case of retroversion it is necessary to understand the principles of treatment. In all cases of retroversion there is a certain amount of descent of the uterus. In a well-marked case the cervix will be found close up behind the pubes, in the axis of the vagina, with the os pointing to the outlet, so that the examining finger passes straight into it (if dilated). In extreme cases the os even points upwards as the patient lies on the back.

The vagina is shortened in proportion to the amount of descent. The first principle, then, is to restore the uterus to its normal position, and despite all that has been said against the use of the sound, I maintain that it is the best means for this purpose. In a few cases, when the abdominal walls are very thin and lax, it may be possible to effect the restoration by

the bimanual method, but even in these the proceeding gives much more pain than the sound. By means of this instrument the uterus can be raised till the fundus touches the anterior abdominal walls without the possibility of injury, provided the cervix be supported by the finger guiding the sound. For this purpose the sound should be well bent, not curved near the point as is usual, but as in illustration (p. 50). In all cases it is essential that the bladder should be empty. Then the sound is withdrawn, and, while the cervix is pressed backwards and the fundus forwards, the intestines are pushed well down behind the uterus, and the organ is left in a state of exaggerated anteversion. The pessary is now applied, and if the sound again pass in the normal direction we have proof that the normal position is maintained. I may here add that this exaggerated position of anteversion has never, in my experience, caused any symptoms.

While it is of the first importance that the uterus be thus placed in its proper position, it is equally necessary that the form of the vagina should receive our attention. The restoration of the uterus to its proper position restores the vagina more or less to its normal length. Now the object of the pessary must be to maintain these two effects. The mode of action of the pessary has been so often described by Goodell, Schultze, and others besides myself, that I need not dwell upon this part of the subject. To put in a pessary without first restoring the uterus to its proper position, in the hope that it will effect that object, has been sufficiently condemned by other writers. Schultze is very emphatic on this point, for he says "no pessary in existence can do this; the normal position must first be restored."

Now it must be remembered that the vagina is a collapsed tube—not an open tube or pipe as authors continually represent it even at the present day—flattened antero-posteriorly, with the two surfaces in close apposition and closely embracing the cervix. This is admirably illustrated by Hart and Barbour. Therefore it follows that any instrument which separates these surfaces to that extent distorts the vagina. Hence also it follows that as it is not possible to devise an instrument that will obviate this entirely, the best is that which distorts it the least. The forms (and names) of the pessaries that are now, or have been in use, are legion, and while much ingenuity is shown in their construction, very little judgment is exhibited. Careful investigation has shown that the form of the vagina may be represented by a thin section through the middle of a pear, the stem end being towards the vulva.

The instrument then which most nearly meets the requirements of the case is the Albert Smith modification of Hodge's pessary, than which I do not believe it possible to devise a better, and when made of material that can be readily moulded to suit the necessities of each case we have all that we can desire. The figure-of-eight pessary has these disadvantages, that if the cervix be enlarged, as it frequently is, it gets strangulated in the posterior opening, and the walls of the vagina are kept too far apart, where the limbs cross one another favouring the accumulation of discharge. This applies to all the others in varying degree. I think I am justified in calling the "ring" pessary the "abomination of abominations." Yet I am told that it is sold by the gross where all other varieties are sold by tens. From its tendency to resume its circular form the effect of this instrument is to shorten the vagina, and thereby continue the descent of the uterus, and to keep the naturally opposing surface widely asunder, &c. Hence we need not be surprised that the men who use this instrument never meet with a case of cure, and therefore form a low estimate of the value of the pessary. It is impossible for a ring pessary to cure a simple case of retroversion. Until recently I had a very large collection of these pessaries ranging in size from the smallest to 4½ inches in diameter. Their removal was always attended with the escape of a more or less copious discharge, often offensive. I am surprised to find that

this form still finds favour with the writers of the two papers I have referred to at the beginning. Under the same condemnation comes Fowler's pessary, and if it be possible to pass a heavier sentence I select the cup-and-stem pessary for it. I have quite recently come across two cases in which this instrument caused intolerable suffering. In one of these only was there any displacement, and in this case the application of a properly fitting Albert Smith-Hodge gave immediate relief, notwithstanding intense uterine congestion.

If ignorance of first principles be answerable for much of the failure to afford relief, or effect a cure by the adaptation of a pessary, want of skill is no less so. From a combination of the two it results that the pessary is often put in doubly reversed, with the infliction of much unnecessary pain. This had so frequently occurred in the case of patients coming from the country that, some years ago, I had to resolve that unless the patient could give me the opportunity of ascertaining the cause of any failure to give relief, I would not undertake the case. Quite recently the breaking of this resolution was attended with distressing circumstances. The patient was a young woman, the mother of one child. She had not been well since the birth of that child, six years ago, suffering from more or less constant pain in the pelvic region, from menorrhagia (for which she had been twice cured), from dysmenorrhœa, headache, sleeplessness, thoughts of suicide and gastro-intestinal troubles, including obstinate constipation. The application of a cup and stem caused her intolerable suffering, and she was at last told that she must make up her mind to be an invalid for the rest of her life. It was under these circumstances that she consulted me. Examination revealed the existence of retroversion, with general enlargement—probably sub-involution—intense livid congestion of the enlarged cervix, and "erosion" of the circle of the os. After a course of treatment, including the use of a pessary, she had improved so much in every respect, and the uterus was in such excellent position that on one occasion I sent her home without the pessary—as a test. Three days afterwards she began to have her old symptoms, and at her request, though with some misgiving, I sent her the pessary. A great deal of pain was inflicted upon her in the effort to introduce the pessary by means of a speculum, and otherwise. After its introduction not only was there no relief but an actual aggravation of the symptoms. In a state of despair she telephoned to me her condition, and I had to ask her to come up at once—a distance of nearly 200 miles. I found the pessary doubly reversed. Its re-application, without any pain, at once relieved her, and now, unconscious even of its presence, she looks to the future with confidence.

The authors of the papers referred to are, as I have said, still in favour of the ring pessary. The former actually gives an illustration of an impossible state of things with the ring *in situ*; and the latter specifically says, that "in uncomplicated cases of cystocele and rectocele a rubber ring pessary usually answers best, whether there be cystocele alone, a rectocele alone, or a combination of the two." I may at once say that a pessary applicable to the treatment of a rectocele has not yet been devised, nor is likely to be, and the only effectual treatment is the restoration

of the perineum. It is quite different, however, in the case of cystocele. For this condition we have a perfect support in the diaphragm pessary, which was introduced to the notice of the profession many years ago in my little book, but which appears to have been overlooked. Here is an illustration.

With this instrument I have obtained excellent results in cases of cystocele and elongated cervix. In one case of the latter in which the cervix had passed through the vulva, a lasting cure was effected. The only difficulty attending its use is that it cannot be kept in stock, and a model has first to be made out of a Britannia metal pessary with elastic bands across. From this model one is made of vulcanite.

There is a general agreement as to the precautions that should be observed in the use of pessaries. That they are not in every case attended to ought not to be charged against their use, but against their abuse. If these precautions were observed we should not hear of "injuries due to neglected pessaries."

As far as present appearances show it seems hopeless to expect that the age of anteversion pessaries will soon be at an end, or of vaginal pessaries for ante-flexion. Yet a moment's consideration of the anatomy of the parts ought to convince any unprejudiced mind that it is impossible to influence for good either of these conditions. Thus anteversion beyond the normal will be due to something behind the uterus pushing it forward, and in such a case the anteversion claims no attention. Anteflexion is in no way influenced by the frequent distension of the bladder, and it is an utter impossibility to exert any pressure on the fundus owing to the intervention of that viscus. As I have already said, anteflexion is not a displacement but a malformation, and must be treated from within. For this purpose the intra-uterine stem—preferably Meadow's combined stem—is often of great service. But seeing that anteflexion *per se* is not necessarily a cause of symptoms until it becomes associated with some degree of obstruction to the escape of the menstrual flow through narrowing of the canal, this instrument now seldom finds a place in my armamentarium. This narrowing of the canal may be only temporary, that is to say during the physiological congestion which characterises the menstrual period, or may be permanent through hyperplasia of the uterine tissue, in which case the internal os will be found to be extremely rigid, so much so as to resist the distensible action of a large laminaria tent for forty-eight hours. Such a tent I have illustrated in my book—and I have seen many of them when dilating for the purpose of curetting. In these cases the process of dilatation is often accompanied by retching or even vomiting, as it is in the use of graduated bougies. These cases are not suitable for the stem pessary, but for gradual dilatation. Did time permit I could give some striking examples of this effect, and I may now state that I have long given up any cutting operation in their treatment.

When it is said that "at their worst pessaries are capable of producing serious injuries and at their best they have inherent drawbacks," I would ask of what method of treatment cannot the equivalent be said, and with far more justice? The writer of these words has drawn up the following indictment against them, *viz.*, "that there is a tendency to set up irritation resulting in constant leucorrhœa (*which I deny*), and entailing the necessity for regular douching; there is the necessity for examination at more or less frequent intervals (*to which I give a qualified denial*), which most women naturally find objectionable (*yes, when, as I have heard, some men are in the habit of removing the pessary for every menstrual period*), there is the uncertainty of results, and, lastly, in favourable cases there is the prospect of a woman having to wear a pessary for ten, fifteen, or twenty years." Apart from the fact that this indictment shows a lamentable want of appreciation—to put it, in the mildest way—of the proper use of the pessary, how does this indictment compare with that which can be brought against his "more excellent way,"

viz., either of the various operations which have been devised, and are now so frequently resorted to for the relief of uncomplicated retroversion? I refer you to the recent report of Professor Oui, read before the recent Congress of Gynæcologists at Rouen, on the influence of these operations on pregnancy alone.

Now, I am not aware that there is on record a single case in which a woman has lost her life through the use, or even the abuse, of a vaginal pessary. On the other hand, what a tale of disaster could be written with regard to the operations I have referred to! Failure in every respect has attended them; immediate failure by death of the patient; failure to effect a cure, or relieve the symptoms; abortion as the result of the imprisonment of the uterus; rupture of the uterus through the same cause; the necessity for Cæsarean section in the cases of women who have previously had normal confinements, and in a considerable number of cases return of the displacement after a succeeding pregnancy; and finally the need of a second operation to remove the effects of the first. Do not suppose that I am drawing upon my imagination for all this. It is all too true. I say that an operation which is certainly not one of necessity, which cannot even be said to be one of expediency, which involves so much risk of life and actual disaster, and which places the uterus in an *unnatural position* is not a justifiable one. At least that is the opinion I have long held, and now with increased tenacity in view of extended results; for my estimate of the sanctity of life has prevented me from adopting the practice even in a single case, seeing that I have been able in a vast majority of cases to afford relief by a perfectly harmless procedure. Some of these operations have already been rejected, notably Mackenrodt's operation of vagino-fixation—an example of "the remedy being worse than the disease"—and each individual operator declaims against the methods of the other.

When a retroversion is complicated by adhesions, inflammatory states of the appendages, or tumour in the uterine wall, it is not the version that calls for treatment, but the complicating condition. Yet I have seen a considerable number of complicated cases in which I have met with unexpected and most gratifying success from the use of the pessary. Did time permit, I could give details of a case of retroversion complicated by a fibroid tumour of small dimensions, just short of being imprisoned in the pelvis, in which a pessary retained the uterus in position until the disappearance of the tumour coincident with the menopause left the uterus in its normal place. This patient wore the same pessary (Britannia metal) throughout. Had this patient any reason to complain of having had to wear a pessary for more than ten years? I trow not.

The pessary is an important aid in the treatment of sub-involution so often associated with, if not due to, the retroversion. In the case of retroflexion properly so called, or as I have defined it, no vaginal pessary can be of any service in undoing the flexion, for the reason that it is impossible to afford direct support to the fundus by its means. In these cases, which, by the way, are very rare, the instrument I use is Meadow's compound stem, and it is remarkable that menorrhagia, which so frequently accompanies this condition, is not only not aggravated, but actually benefited by it. That many cases of retroversion of long standing have some amount of flexion super-added is unquestionable, from long-continued intra-abdominal pressure on the anterior surface. But these are essentially retroversions. This posterior flexion appears to me to constitute a strong argument against the current doctrine that anteflexion is the normal form of the uterus. In a case of true retroflexion a vaginal pessary simply aggravates the flexion by doubling the uterus still further upon itself.

Now arises the question, of what material should the pessary be made? The rubber or celluloid-covered wire, the vulcanite, and Britannia metal, all find their

advocates. The pessaries I have had to remove most frequently and accompanied by the most offensive discharge have been the first-named. The idea of putting a cushion on the posterior crossbar, filled with air or glycerine, to support the fundus not only shows an ignorance of the action of the pessary, but is a physical mistake; for, in a short time, the cushion collapses and presents a horribly corrugated surface, with what result I need not describe. I am informed that these cushions are now filled with gelatine, but that does not alter the principle. The vulcanite is open to only one objection, viz., that it is very difficult to alter the shape, and, as Marion Sims said, "the man who is not a mechanic should not trust himself to use a pessary." I have tried the celluloid, which finds so much favour with Schultze and his followers, but others as well as myself have found that it does not retain its shape unless nearly straight. The most suitable and convenient material, according to my experience, now extending over a period of about forty years, is the Britannia or white metal. The shape is most readily altered, and is retained, and the metal itself offers this advantage—that it gives notice of the presence of any irritating muco-purulent discharge, by becoming more or less black. It is also very easily cleaned and polished, and can be worn for years. Were it not for the difficulty of moulding it the best material of all would be aluminium on account of its extreme lightness and non-liability to corrosion by any discharge. But this difficulty and the cost militate against its more general use.

I have now shown that the pessary when properly used, and not abused, involves no danger whatever, but is worthy of our full confidence, that the charges that have been brought against it cannot be justly sustained; that in its results it compares most favourably with the operations which have been substituted for it, and that it is an entire misrepresentation of the case to say that "the operative measures" to which I have referred "do all and more than all that pessaries can do without their manifold drawbacks and risks."

If I had done nothing more than afford the relief which the pessary has enabled me to give I should now feel that my professional life had not been ill-spent, and if I have failed in some cases I have at least the satisfaction of having done no harm. I may have used some strong expressions in the course of this communication. If I have done so it has been from a sense of duty, and if I had a hundred tongues I should use them for the purpose of trying at the least to put a curb upon the frequency with which the operations to which I have referred are performed.

THE URINE SEPARATOR OF LUYS. (a)

By FRANCIS M. CAIRD, M.B.ED., F.R.C.S.,
Assistant Surgeon to the Edinburgh Royal Infirmary; Lecturer on
Surgery, Edinburgh Medical School.

THE instrument had been introduced only a comparatively few months ago, but it had already shown itself to be a valuable addition to our armamentarium in all genito-urinary cases in which it was important to ascertain how each of the kidneys was functioning. The instrument in its approved form consisted of the following parts, and in order to get trustworthy results it was essential that it should be properly constructed. In shape it resembled an old-fashioned catheter with a straight shank and a sickle-shaped extremity. It was the size of a No. 4 bougie, and in using it one essential point was to ensure that the whole of the curved part was completely in the bladder. The instrument consisted first of a metal rod, curved as described, and having

attached to its point a fine chain which lay along its concave aspect, and terminated by being affixed to a screw on the handle of the instrument. The rod and chain were enclosed in a thin rubber cover. On each side of the rubber-clad rod and chain there was a catheter, semicircular on section, the flat side being apposed to the rod. The two catheters and the rod and chain were arranged so that their points fitted into a rounded thimble, which held all three together, and converted them, as it were, into a single bougie. By tightening up the screw to which the chain was attached, the latter, of course, formed an arc to the circle composed by the curved rod, and in doing so drew up the elastic covering so as to form a diaphragm filling up the sickle-shaped concavity of the rod between the two lateral catheters, and thus forming a partition between them. The instrument was used as follows:—After washing out the bladder and leaving in it a few ounces of sterile salt solution, the separator was passed like an ordinary catheter. Any difficulty which might be experienced could be got over by putting a finger in the rectum or vagina to guide it, and at the same time to make sure that it was really in the bladder. As soon as it was *in situ*, the patient was raised into the semi-recumbent position, the thighs were separated, and the handle of the instrument was steadily held *exactly in the middle line*. Then the salt solution in the bladder was allowed to escape by the catheters, whereupon the bladder contracted down on the separator, which was lying exactly between the two urethral orifices. By tightening the screw and so raising the chain with its rubber diaphragm, the bladder was then divided into two practically water-tight compartments, into each of which a ureter opened. Then on the separator was hung a frame containing two test tubes, one below the mouth of each catheter, and into these the urine from each kidney was separately collected. A good test of renal adequacy was supplied by the intra-muscular injection of a three per cent. solution of indigo-carmin, which under normal circumstances, was excreted by the kidney about ten minutes after its introduction into the circulation, while if the kidneys were diseased the blue colour was not communicated to the urine for several hours. Besides this test, the urine from the two kidneys should be compared as to reaction, bacterial content, specific gravity, urea, freezing point, &c. A number of case records illustrating the use of the separator were read, diagrams of the tubes of urine from each kidney being shown. It was shown that the use of the separator had led to the affected kidney being removed in a case of tuberculous disease in which the right organ was enlarged and tender. The urine from the right ureter, however, being normal, while that from the left was scanty and not discoloured by indigo-carmin, showed that the left kidney was the diseased one; it was removed, and at the same time the enlargement of the right kidney was found to be due to compensatory hypertrophy. In such a case as this, to have been guided by the clinical examination only would have been to court disaster. In other cases a separate examination of the urine from each kidney had either allowed of the extirpation of the affected organ, or by showing that neither kidney was adequate had prevented rash and unnecessary operations.

(a) Abstract of Paper read before the Edinburgh Medico-Chirurgical Society, July 5th, 1905. For discussion see page 57.

SOME OF THE LESS COMMONLY RECOGNISED PHENOMENA ASSOCIATED WITH RICKETS.

By JAMES BURNET, M.A., M.D., M.R.C.P. EDIN.,

Senior Clinical Medicine Tutor, Extramural Wards, Royal Infirmary; Registrar, Royal Hospital for Sick Children; and Physician to the Marshall Street Dispensary, Edinburgh.

Of all diseases met with during infancy, rickets is undoubtedly one of the commonest. The ordinary symptoms are too well-known to need mention here. We are at present more concerned with certain of the less commonly recognised phenomena occurring in the course of this disease. Most of these are, perhaps, somewhat rare, while others which we shall also refer to are exceedingly familiar in the course of everyday practice.

The condition known as "facial irritability" is a very common manifestation of rickets. When we tap with the forefinger over the masseter muscle on either side we obtain a reflex contraction of the muscles of the forehead corresponding to the side of the face tapped. This phenomenon is not always present, but it is one which should be looked for in every case. When it is obtained, it means that the nervous system is affected, and the patient will either be found to have had fits previously, or if not is exceedingly liable to suffer from them on slight provocation in the near future, unless treatment is promptly carried out. As a valuable index, therefore, to therapeutic measures, facial irritability must be carefully kept in mind. Of one hundred consecutive cases of rickets examined we found this phenomenon present seventy-one times.

Laryngismus stridulus is a curious condition occasionally met with. The infant has crowing fits in which the breath seems to stop for an instant, and then relief is obtained by a long-drawn stridulous inspiration. It is simply a reflex spasm of the larynx, and is readily induced by very trivial causes. It is often termed "croup" by the laity, but is seldom serious, although it indicates great instability of the nervous system. Convulsive seizures sometimes follow upon, but more usually alternate with, such attacks. The treatment is essentially that of the underlying condition, namely, rickets. The patient must be properly fed, not on artificial food of all descriptions, but on milk and, if old enough, on oat-flour and eggs, which are rich in fat. In addition, douching of the spine with cold water after the morning bath is excellent as a means of bracing up the nervous system. A valuable aid to treatment is virol, which contains malt, eggs and meat-juice in a highly assimilable form. This may be given in amounts varying from one quarter to one teaspoonful thrice daily according to the age of the patient.

A third rachitic manifestation is tetany; in fact, some authorities regard laryngismus stridulus as merely a suppressed form of tetany. The latter condition is certainly brought about by reflex excitation of the nervous system, but in what way has never been exactly determined. From the fact that gastro-intestinal disturbances are frequently associated with tetany, we were led to the conclusion that probably a careful examination of the abdomen might reveal some

causal condition. By auscultatory percussion in a number of cases of infantile tetany, we have made out a considerable degree of gastrectasia. It is a recognised fact that dilatation of the stomach is sometimes associated with tetany in the adult, and we have placed on record (*Practitioner*, December, 1903) a case of gastric carcinoma with well-marked gastrectasia, in which death was preceded by tetany. In view of this we may fairly conclude that tetany and gastrectasia are closely related in early life. The gastric dilatation which occurs in rachitic babies is largely the result of muscular atony, but it is no doubt also partly produced by the improper feeding which underlies the original condition. So far as the treatment of tetany is concerned, we must employ measures which will diminish the spasm. Nothing succeeds so well as the combination of sod. brom. and phenazonum. In addition, cold douching of the spine is a most valuable help. Should the stomach be found to be dilated, lavage may be tried, although in some cases we have found it aggravate the condition. Care should be taken regarding the feeding of the patient. Nothing but milk should be allowed, and only small feeds should be given at regular intervals. Fresh air is requisite also, and accordingly the infant must be taken out every day. The after-treatment should be directed to the removal of the underlying rachitic condition. For this suitable feeding is required just as in laryngismus stridulus.

A curious rachitic condition is that of "head nodding," or spasmus nutans, as it is otherwise termed. The patient's head resembles in its movements those of the toy animals with movable heads, and it either keeps moving from side to side or backwards and forwards, as if it were centred on a pivot. In every case the patient suffers from rickets, but it has been stated that the real source of this phenomenon is want of sunlight. Such infants are said to have been brought up in dark rooms or to have lain in a crib placed in a dark corner of the apartment. This, however, has not been our experience. During the past three or four years we cannot remember seeing a single case in which such a history was obtainable. In fact, on the contrary, one of our best-marked cases was that of a baby whose home we visited personally in order to investigate this particular point. The room was a large one, well lit and facing due south. The child's crib was opposite the window, and the house was scrupulously clean. The rachitic condition was in this instance induced by the use of an artificial food, which had been given to the infant almost from birth. By stopping this and putting the patient on pure milk, with the additions mentioned later under treatment, a cure was ultimately effected.

Head-nodding is frequently co-existent with another condition known as nystagmus. These two, indeed, almost invariably occur together. Like head-nodding, this is a purely nervous phenomenon, and is induced by the want of tone in the nervous system which rickets sooner or later brings about. No special treatment is necessary beyond that already mentioned. We have known the condition to be very persistent and one case recently under our care had lasted for nearly five months. By the use of cold spinal douching, a suitable dietary and the administration of virol the nystagmus gradually disappeared, as did also

the head-nodding, with which it was intimately associated.

Adenoids is probably not a condition which is looked upon by the profession generally as being of rachitic origin. They are very prevalent, however, in rachitic children, so that we incline to the belief that hypertrophy of the lymphoid tissue composing the pharyngeal tonsil may readily be induced in infants affected with rickets. It is now well-known that adenoids are met with during the period of infancy, their presence being sometimes indicated by noisy breathing and difficulty in suckling, while snuffing is by no means uncommon in such cases. The noisy breathing of adenoids has to be distinguished carefully from congenital laryngeal stridor. The latter is present from birth and is not worse at night, while in adenoids this symptom is rarely manifested until after the sixth month, and is always aggravated at night. Adenoids is such a common affection in early life that, relying on the theory of their rachitic origin, we would do well to guard against the occurrence of rickets, and when this disease does make its presence felt, great care should be taken in its treatment.

In rachitic infants, otorrhœa is a very common occurrence. If we examine the tympanic membrane in infants affected with rickets we shall rarely find it absolutely normal. In fact, a catarrhal condition of the ear is but one of the catarrhal states which rickets produces and is akin to the vomiting, diarrhœa, rhinitis, conjunctivitis and bronchitis occurring during the course of this disease, and which are all undoubtedly of similar origin. Accordingly, the treatment, although local to some extent, must be guided by general principles, and in every case careful dieting, fresh air, and the use of virol, or, if preferred, emuls. ol. morrhuæ, must be enjoined.

The following table gives the number of cases presenting one or other of the conditions we have referred to in a consecutive series of one hundred rachitic infants who have been under our care. In some instances more than one condition was manifested by the same patient :—

Facial irritability	71
Otorrhœa	34
Laryngismus stridulus	8
Head-nodding	2
Tetany	3
Nystagmus	2
Adenoids (1 doubtful)	2

These numbers refer to infants. Adenoids induced by infantile rickets usually do not come under medical treatment until the period of childhood is reached.

Regarding the treatment of these and other manifestations of rickets, the following simple rules should be kept in mind :—

1. The diet must in every case be carefully investigated. All forms of artificial food should be stopped. Breast-feeding should not be allowed after the ninth month; and nothing but milk permitted before that period if the infant is brought up by hand. After the ninth month, oat flour, eggs, gravy, but no starchy food, may be allowed in moderation.

2. Cold douching of the spine should be ordered as a routine measure. It is best given in the morning after the ordinary bath has been taken. If given before the fire with the feet in a little tepid water no chilling effect will be produced.

3. Fat must be supplied in every case. Oatmeal, egg yolk, and cream may be ordered for this purpose. So, too, emulsions of cod-liver oil are invaluable in this connection, while petroleum emulsions; as we have frequently pointed out, are absolutely valueless. The latter simply act as lubricants, are not absorbed, and may actually produce vomiting and diarrhœa. During the summer months we prefer virol, which contains a large percentage of fat in a very readily assimilated form. It does not produce gastro-intestinal irritation which cod-liver oil is very apt to do in hot weather. In fact, we are now in the habit of substituting it for cod-liver oil emulsion whenever the warm weather sets in, while in a large number of cases we have prescribed virol from the very first. It is always well tolerated, and its pleasant taste makes it agreeable to infants who readily dislike nauseous drugs. It acts satisfactorily upon nutrition in all rachitic cases, and infants to whom it is given generally show a rapid gain in weight.

These remarks are intended merely to serve as suggestions. They indicate the lines along which treatment must be carried out. In conclusion, too great care cannot be taken to secure the well-being of rachitic patients, as, should acute disease supervene, they lack the necessary resisting power, and not infrequently succumb to what would, in a normal healthy infant, prove to be merely a slight illness. Moreover, chronic bronchial catarrh induced by rickets leads to permanent deformity of the chest, which may prove of serious import in later life. These are but some of the reasons why the treatment of rickets is always a matter of extreme importance. To the thoughtful physician others of no less consequence will doubtless suggest themselves.

French Clinical Lectures.

STRICTURE OF THE OESOPHAGUS.

By A. VINCENT, M.D.

Professor of Surgery at the Medical School of Algiers.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

HERE is a man who comes to us complaining of a difficulty in swallowing. He first noticed it some four months since, and then it only occurred at certain times, or on endeavouring to swallow particular articles of food, especially meat, that he constantly felt a hitch at a point behind the manubrium sternum. He first attributed it to indigestion, and this view, he tells us, was confirmed by several medical men whom he consulted. Try as he would to explain it away, as of no particular importance, the difficulty steadily increased, until he was obliged to nourish himself exclusively on slops, for he could still swallow liquids with tolerable ease. At the same time, possibly in consequence of his change of dietetic habits, he lost weight. From being a stalwart man with a tendency to obesity, weighing in fact some 84 kilogrammes, he now only weighs 69 kilogrammes, so that in the last four months he has lost some 15 kilogrammes, a rather alarming reduction. Of course, the loss of flesh may or may not be due to the fact that he has not been able to take the usual amount of food, but in any case his inability to partake of meat must be accorded a share in its causation.

He tells us that the difficulty consists in a feeling of constriction at the lower part of the œsophagus on swallowing, not exactly a pain, but merely a feeling that the food "sticks in his gizzard" so to speak. He denies ever having vomited or regurgitated food after a certain lapse of time (which would indicate the presence of a pouch), and he says he has never brought up any blood.

You will note that he appears to be a healthy man, and fairly robust, though his face bears traces of the anxiety which no doubt he feels at being obliged to come to the hospital for relief. Like so many of our patients he greatly desires to be relieved, but he almost as strongly resents the idea of any surgical intervention and, as you are aware, we surgeons are often suspected of a desire to operate, apparently for experimental purposes, whenever we get a chance. His complexion is of a healthy tint, he is hardly what you would call emaciated, in spite of his loss of flesh, and he is still, from a muscular point of view, reasonably strong. He has always been a man of active habits and has no doubt lived well, an expression that covers a multitude of dietetic irregularities.

The question we have to decide, in the interests of both prognosis and treatment, is as to the cause of this stricture of the œsophagus. He himself, apparently inclines to the view that it may have something to do with his past venereal history. He denies having had syphilis, but he admits having, on two different occasions, had a sore or chancre, the last some eighteen years ago. So far as he is aware the lesion was of the nature of a soft chancre on both occasions, in any case the first was not followed by any constitutional symptoms and healed after a two or three weeks local treatment. Some six weeks after the second, however he had an eruption of some kind, which "he is sure" was not syphilitic. As he presents no trace of specific cutaneous lesions we must leave this question unanswered and in any case syphilitic strictures of the œsophagus are of extremely rare occurrence.

We will now proceed to pass an œsophageal bougie. You will note that I am careful to commence with the largest size. This is a highly important detail, because if you begin with a small bougie you may catch the point in a fold of mucous membrane and be led to diagnose the presence of a stricture which has no existence. Only the other day I was called in consultation not far from Algiers in the case of a woman who had for some time suffered from symptoms suggestive of stricture of the œsophagus. The doctor in attendance had done his best to make sure of his diagnosis. He had introduced a small bougie, but was unable to reach the stomach, it being arrested some three inches from the cardiac orifice. I repeated the manoeuvre, but, in accordance with the principle that I have just laid down, I used the largest size, and it passed into the stomach without the slightest difficulty, rather to the doctor's confusion.

You see that the bougie I am using becomes impacted at a distance of, roughly speaking, eleven inches from the teeth. Attempts with the smaller sizes prove equally unsuccessful in reaching the stomach so that we can have no doubt as to the existence of a genuine narrowing of the œsophagus—a narrowing which, indeed, has reached a serious degree of stricture.

You will agree with me when I tell the patient

that the stricture *may*, after all, be syphilitic and *may* yield to medical treatment, though I cannot absolutely promise that he will recover the power to swallow in its integrity.

Now that the patient has left the room we are at liberty to discuss the nature of the stricture more freely. You must not take seriously what I told the patient, because it is our duty always to encourage hope, the more so as in this instance it is probably all that is left to him. I have little doubt, in view of the circumstances, that the stricture is due to a malignant growth, a neoplasm as it is conveniently called, for the terrible word cancer is one which we must accustom ourselves never to use except between ourselves. I venture to tell him that it will be necessary, or at any rate desirable, in order to enable him to take a proper amount of nourishment, to make an opening into the stomach. Gastrostomy is an operation practically devoid of risk, and it will have for immediate effect the improvement of his general health. He will put on weight and imagine that he is getting well. Alas! if my diagnosis be correct the improvement will only be temporary, for the disease will pursue its course and ultimately cause death in the usual way. Nevertheless we shall have rendered him a signal service since his end will be peaceful and he will be spared the terrible sufferings of death from gradual inanition. That is something to be grateful for and unfortunately, it is all that we can do for him, the growth not being in a situation which allows of our obtaining access there to, for the purpose of a radical removal by operation.

Of course the victim of stricture of the œsophagus is deprived of the pleasure of eating, a deprivation of which one does not suspect the importance until one undergoes the ordeal. It is so necessary that we should eat that Nature has made the act a pleasure, consequently we do not eat merely because we are hungry, but partly because the flavour of the aliments is agreeable *per se*. After a time, the monotony of absorbing nourishment without the privilege of masticating and swallowing it, engenders marked depression of spirits, but this can be obviated by allowing the patient to masticate some of the food he is taking, not of course attempting to swallow it, but merely for the purpose of gratifying his gastronomic propensities.

I have not dwelt at any length on the differential diagnosis of stricture of the œsophagus in this case, for the simple reason that in a man of his age and in the absence of any obvious cause of injury from within or pressure from without, such strictures are practically always due to neoplastic thickening of the œsophageal wall. Whether malignant or not, gastrostomy is indicated if only to give the parts rest. The constant and ineffectual attempts to swallow solid food set up, or increase, the local irritation and *pro tanto* tend to aggravate the stricture. This course is doubly urgent when we suspect malignancy, because tissue that is undergoing cancerous degeneration is very friable and is therefore easily injured, in which event we get inflammatory phenomena superadded to the existing lesion.

I do not really suppose that his syphilis—for there can be little doubt that his second chancre was syphilitic—has anything to do with his œsophageal lesion except that this disease seems, in a sense, to prepare the soil for cancerous

degeneration. Of course, in the present state of our knowledge, we should not be justified in asserting that syphilis caused cancer, but it certainly appears to prepare the way, to make the tissues more vulnerable thereto, and this is indeed only what we should expect when we remember what a profound constitutional morbid influence syphilis brings to bear.

Transactions of Societies.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.
MEETING HELD JULY 5TH, 1905.

PROFESSOR CHIENE, C.B., in the Chair.

DR. ALLAN JAMIESON showed a case of *granuloma rubra nasi*.

Dr. G. A. GIBSON showed two cases of syringomyelia, one of three years' duration, which began with the appearance of blisters on the fingers and arms and difficulty in executing fine movements with the fingers, and now presented dissociated anæsthesia (there being anæsthesia to touch over the areas of the 8th cervical and 1st dorsal root on the right side, and the 2nd, 3rd, and 4th dorsal roots on the left, while analgesia extended over the region supplied by the nine upper dorsal roots), wasting of the small muscles of the hands, and an extensor plantar response. The other was of short duration; there was no tactile anæsthesia, but there was left hemianæsthesia to pain and temperature. In the differential diagnosis, hysteria was excluded by the plantar reflex being of the extensor type on the left side, and by the presence of paralysis of the left cervical sympathetic.

Mr. COTTERILL showed a man, æt. 36, who had consulted him six months previously on account of a tumour of the side of the face of three months' duration. The tumour was in the parotid region, and as it was giving rise to great pain and was associated with exophthalmos, a diagnosis of sarcoma in the sphenomaxillary fossa was come to. Treatment with X-rays failing to benefit, the patient was discharged as incurable. He had recently returned, however, and as the tumour had grown no larger the diagnosis had required revision, and now lay between tubercle and a parotid growth of some kind. (2) A case of perforating ulcer of the right foot, associated with abolition of the knee-jerk and anæsthesia on that side, due evidently to a peripheral neuritis, there being no signs of locomotor ataxia. The ordinary statement that perforating ulcer healed with difficulty was contradicted by this case, for, although the subjacent joint was destroyed and its cartilages eroded (a condition which would have rendered the healing of any ordinary ulcer more than problematical), simple application of boric dressings had brought about rapid cicatrization. In treating these perforating ulcers the important point was to prevent a downward funnel-shaped growth of epithelium round the edges; if this were done they would be found to heal readily enough.

Mr. C. W. CATHCART showed (1) a patient after wiring a recent fracture of the femur on account of malposition, and (2) a patient who had had a very extensive depressed fracture of the skull, which had been successfully elevated.

Mr. J. W. STRUTHERS showed (1) an elderly man after radical cure of a double inguinal hernia by Bassini's method. The operation had been done under local anæsthesia with perfectly satisfactory results, as the patient had continued at his work as a labourer for a year without any sign of recurrence. (2) A patient after excision of the astragalus for compound subastragaloid dislocation of the ankle.

Mr. J. M. COTTERILL showed (1) a series of gall-stones, and (2) a series of damaged semilunar cartilages removed from the knee-joint.

Mr. ALEXIS THOMSON showed (1) specimens from a case of cholecystectomy for gall-stones and pendulous

gall-bladder. (2) Enlarged prostate vesical and calculus removed by suprapubic operation.

Dr. MICHAEL DEWAR read a paper on

THE RECENT EPIDEMIC OF INFLUENZA.

Introducing his remarks by a brief historical sketch of the malady, he alluded to the epidemic of thirty years ago, which was of so benign a type, and so slightly fatal, that his teacher, the late Professor Laycock, passed by the disease in his lecture with only a word or two. Of the three recent epidemics, that of 1889-90 chiefly affected the nervous system, and left behind it prostration, mental depression, and again nervous disease; many of those who suffered were never the same again, and not a few died within a year or two. Next came the epidemic of 1898, in which elderly people suffered most, while children escaped. The symptoms were chiefly referable to the cardiac and respiratory systems. Finally there had been the epidemic of the present year, which was the subject of his remarks. In his practice he had had about fifty cases of genuine influenza, excluding ordinary febrile catarrh. These began about the middle of January, and declined about the middle of February, reaching their maximum about January 31st. He depended for diagnosis on excluding all other diseases, the only other test being the bacteriological recognition of the bacillus in the sputum, which was not always a practicable matter. True influenza, due to Pfeiffer's bacillus, must be distinguished from the milder disease, grippe, which bore the same relation to the former as cholera nostras did to Asiatic cholera, its cause being quite unknown. Influenza was of three types, a cardio-pulmonary, a gastro-intestinal, and a nervous variety. The features of the first were high fever for the first two days, then a lower temperature, and a return to normal during the second week. There were either bronchial or cardiac symptoms, and adults of both sexes, as well as children, were equally affected. The gastro-intestinal cases generally occurred among children and male adults; pain in the right hypochondrium and below the right shoulder was a very constant symptom. In cases in which the nervous system was chiefly affected the temperature was low, and soon fell to subnormal, where it remained for a week or more, accompanied by a slow, feeble pulse, before the usual level was reached. A number of illustrative cases were read, including some showing both pulmonary, gastro-intestinal, and nervous symptoms. Speaking of treatment, Dr. Dewar related his own methods, but laid stress mainly on nursing. He concluded by pointing out that influenza tended to occur in epidemics at intervals of seven or eight years, and that each lasted for six or eight weeks. In gastro-intestinal cases the special form of pain he mentioned—in the right hypochondrium and below the right shoulder was a very constant symptom. Coryza, on the other hand, was often absent.

Dr. RITCHIE discussed the paper, agreeing that the last epidemic had been a comparatively mild one. He always employed stimulants, such as camphor, nuxvomica, or alcohol, from the very onset, and never gave antipyretics. Headache was usually due to frontal sinus catarrh, and was best treated by hot applications. He deprecated calling every trifling feverish catarrh an attack of influenza.

Mr. F. M. CAIRD read a paper on

THE URINE SEPARATOR OF LUYIS,

an abstract of which will be found on page 53.

In discussing the paper, Mr. CATHCART spoke of the difficulty he had experienced in introducing the instrument in women on account of uterine enlargement or displacement. He preferred to precede the separator by cystoscopy, and had not found that the introduction of the former was attended by so little discomfort as in Mr. Caird's hands.

Mr. WALLIACE had found that in cases of prostatic enlargement it was sometimes very difficult to introduce the separator. He agreed that it was a safer appliance than the urethral catheter, though those who had employed the latter and acquired the necessary manual dexterity preferred it to Luys' instrument.

Dr. T. D. LUKE read

REMARKS ON POST-ANÆSTHETIC SICKNESS.

Post-anæsthetic sickness was often the most trying sequel of an operation, its occurrence was influenced by the nature of the anæsthetic, the nature of the operation, the mode of administering the anæsthetic, the thoroughness with which the patient was prepared, and the physical condition, age, sex, and temperament of the patient. Sickness was most frequent after ether inhalation, but more severe and lasting after the administration of chloroform. Special mixtures had no special effect one way or another in causing sickness. It occurred after ethyl-chloride in only about 15 per cent. of cases—less frequently, that is, than after any other anæsthetic except nitrous oxide. Drug treatment of anæsthetic sickness was palliative. In certain cases washing out the stomach was of value, but the main indication was to favour the elimination of chloroform from the body tissues in every way.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

MEETING HELD FRIDAY, JULY 7TH, 1905.

Mr. JOHN TWEEDY, P.R.C.S., President, in the Chair,

Mr. R. R. CRUISE described a case of

MICRO-OPHTHALMIC CYST OF THE ORBIT.

The patient, æt. 24, from birth had had a swelling in her left orbit which had been increasing in size for the last two years. There was a small degenerated looking micro-ophthalmic eye pushed into the upper and outer quadrant of the left orbit. The rest was filled with a fleshy mass which was firm and fluctuating. There was a coloboma of the iris, lens, and choroid in the right eye. The left orbital contents which was cystic was removed. On examination the sclerotic was deficient in its posterior half, and through this the retina protruded into the cyst. The iris was adherent to the cornea in its whole extent. The lens is displaced backwards and held in position by a strong band of fibrous tissue attached partly to the globe and partly to the cyst. The cyst enveloped the globe above, below, and to the nasal side. The microscopical characters and peculiarities of the eye were carefully described and showed various developmental peculiarities, while the choroid had some fine bone developed in it. Clinically the diagnosis was by no means easy, especially the differential diagnosis between it and meningocele. Pathologically the chief peculiarity was the free communication between the eye-ball and the cyst, which allowed the free passage of fluid secreted by the well-developed ciliary body to pass into the cyst, and this led to the increase in size of the cyst for which reason the patient applied for treatment.

Mr. SIMEON SNELL (Sheffield) gave details of a case of

SYMPATHETIC OPHTHALMITIS

in which normal vision was restored in the exciting and sympathising eye. The patient was a man, æt. 33, whose left eye was wounded on September 8th, 1904, and when seen for the first time eleven days later there was a wound of the cornea extending into the ciliary region with a prolapse of the iris. The prolapse was at once excised, and the eye healed without further trouble. On October 2nd, the right eye was noticed to be red, and five days later there was iritis, and it was then noted as being a severe case of sympathetic ophthalmia. About a month later, the pupil began to act and the eye to whiten. Since then recovery had been perfect and vision is now $\frac{6}{5}$ and J1 in each eye. Mr. Snell referred to another similar though less severe case which he had recorded in the *Transactions* for 1883. Mr. Snell recorded also three cases in which sympathetic ophthalmitis had come on after excision of the eyeball. The first was a boy, æt. 10, who had a large wound of the cornea and sclera. Sixteen days later the eye was removed. Three weeks later there was sympathetic ophthalmitis. The disease ran a severe course, and the patient can now, fifteen months after the accident, find his way about and read large print. Another case was

a man, æt. 26, whose eye was wounded by a kick which involved the cornea-scleral junction. Sixteen days later the eye was excised. A month later Mr. Snell saw him for the first time, when there was marked sympathetic ophthalmitis in the other eye which had commenced a week before. It was a severe case, and practical blindness resulted. He also referred to another case, that of a girl, æt. about 10. The dates, however, could not be given. He referred to a case he published in the *Transactions* for 1882, in which the disease showed itself thirty-two days after excision and 106 days after the injury. Thus, of these four cases, one was mild and recovered, three were severe, and two of them were totally blind. The Report of the Society's Committee stated that such instances were of a mild form, and that out of thirty cases eighteen completely recovered, three partially, and nine were lost. Mr. Snell also reported a case of a further instance of glioma, in more than one member of the same family. He referred to the paper he read before the Society last year in which he related an instance in which two members of the same family were affected. At that time only three observers had placed cases on record. He now related a further case. The patient was a male child, æt. 3½, and glioma was present in each eye. One eye had been noticed affected a few months after birth, and the other a few months ago. It was then ascertained that the only other child of the parents was a girl born in 1897, who was similarly affected with glioma in both eyes, and which proved fatal. Mr. Snell mentioned the fact that the child whose case he had recorded last year was still alive and well.

Mr. MAYOU read a paper on

SECONDARY TUBERCULOSIS OF THE IRIS WITH SPONTANEOUS RUPTURE OF THE LENS CAPSULE.

The patient was a boy, æt. 3, who for some time previously had suffered from tuberculous dactylitis. The eye was inflamed for three weeks before being seen. Masses of tubercle were then seen on the iris which was very much inflamed. Hæmorrhage took place later on into the anterior chamber and the eye was removed. On examination it was found that the iris was adherent to the posterior surface of the cornea and Descemet's membrane was perforated, while the substantia propria was infiltrated. The mass on the upper part of the iris was adherent to the cornea and to the anterior and posterior part of the lens capsule and contained giant cells, but no epithelioid cells or tubercle bacilli were seen. The anterior capsule showed a large gap evidently produced by the softening of the tubercle followed by cicatricial contraction. The retina also showed masses of round-cell infiltration similar to that seen on the iris. The chief points of interest were the unusual situation at which the tuberculous mass had invaded the cornea; the spontaneous rupture of the lens capsule; the nature of the exudation in the retina; and the general tendency towards cicatrization.

Special Articles.

THE ARMY MEDICAL REPORT.

THE Report of the Army Medical Department for the year 1903, which was not issued until a few days ago, forms, as far as its nature permits, most interesting reading, and may be regarded as, on the whole, satisfactory. To criticise, or even refer, to one tithe of the immense amount of statistical material which it contains would be absolutely impossible, and consequently it is necessary to confine ourselves to one or two subjects.

The paragraphs dealing with the recruiting of the Army are at present of great interest owing to the recent investigations into the causes of the supposed physical degeneracy of the nation. Turning to them, we find that the number of recruits inspected during the year was 69,553, of which nearly one-third, or 22,382, were rejected as unfit, and that a further 1,022 were discharged within three months of enlistment,

bringing the total number of rejections up to 23,404, or to a ratio of 336.49 per 1000. The highest ratio of rejections per 1,000, it is interesting to note, was afforded by England and Wales, and the lowest by the Colonies, while Scotland and Ireland occupy intermediate positions in the order named. The ratio shows a decided increase as compared with the previous year from all sources, the increase in the case of persons born in Scotland being 56.85 per 1,000. It is a very important fact to note that the greater proportion of candidates offering themselves was derived from the class of labourers and husbandmen, and that this class also yielded the highest percentage of rejections. It is a pity that a little more detailed information is not given concerning these, because, as the Report reads, it would seem that the causes of unfitness were as prevalent among the rural as the urban population, and would therefore be contradictory to many of the results that have lately been obtained by an investigation into the national physique. This fact is even more striking since defective general development accounted for as many as 4,911 of the total rejections, and yet we find that there is an increase among the accepted recruits of men under one hundred pounds weight and under 31 inches chest measurement. As regards the education of the recruits it is curious that an increase of 17 per 1,000 has taken place in those returned as "well educated," and at the same time there has been a decrease of 21 per 1,000 of those able to read and write.

The vaccination statistics show that there has been an all-round slight diminution in those bearing marks of vaccination and derived from the United Kingdom, but this has so far had no ill-effect, as there were only two admissions for small-pox during the year, one at Chatham and the other at Cork, as compared with eleven admissions in 1902. Re-vaccination continues to be actively carried on as proved by the fact that no less than 45,075 were performed during the year. Of these re-vaccinations nearly 40,000 were done on recruits.

As regards enteric fever, we note that there has been a slight decrease in both the number of admissions in the United Kingdom and in the death-rate; the latter is, however, still high, as 28 deaths occurred out of a total of 92 cases. Out of the total number no fewer than 27 cases were admitted from Aldershot. In South Africa there were 1,155 admissions with 138 deaths, the disease accounting for nearly 46 per cent. of the total deaths in the command. Among the special points of importance in this connection are (1) the continued high rate of incidence among men who have just arrived in Africa; (2) that intermittent contamination of the water supply has been shown to occur at Pretoria, rendering necessary universal boiling of the drinking water, even when derived from springs that gave a good analysis; (3) the discovery that an aerated water supplied by one large manufactory contained the *B. coli communis*; (4) renewed evidence of infection being conveyed by flies, as in the outbreak among the Leinster Regiment at Pretoria. This cause is also held to be the most important one in accounting for the considerable increase of enteric fever in the Indian forces, and attempts are being made to eliminate it by greater care in connection with latrines, &c. Before leaving the subject of enteric fever we may say that the report dealing with it in connection with India is one of the most valuable in the whole volume. Its excellence and length prevent us from referring further to it.

The report on malarial fever in India is also most valuable. There has been a considerable decrease in both admission rate and death rate, which we suppose may be partly attributed as in Crete and in the Barbados command to the anti-mosquito measures which have been adopted. On this point, as is well known, there is an acute difference of opinion, but the present statistics at any rate show that more scientific and rational means of prophylaxis are being undertaken and apparently with success.

Innumerable other subjects are worthy of discussion,

but we must conclude by referring anyone who desires more information to the volume itself, which forms a fine record of the work done by, and of the scientific abilities of, the members of the Army Medical Service.

France:

[FROM OUR OWN CORRESPONDENT.]

Paris, July 18th, 1905.

TREATMENT OF HYDRARTHROSIS OF THE KNEE.

THE treatment of hydrarthrosis of the knee by hot air was first recommended by Klapp, of Germany, and the apparatus for this purpose is of the most rudimentary kind. A small wooden box and an ordinary paraffin lamp. Both ends of the box are removed and replaced by two cylinders of sheet iron or tin. The leg of the patient is passed through the box, and the ends of the cylinders stuffed with cotton wool around the leg to prevent the escape of the heated air. A hole is made in the side of the box to which is fixed a small tin tube slightly curved, so that the free orifice looks directly downwards, and in which penetrates the glass of the lamp. Another small hole is made in the top of the box to create a draught, in which a thermometer might be adapted. It remains only to light the lamp. The temperature should be about 158° F., and the *seance* lasts from half an hour to one hour, repeated three times a day. M. Antoine recommends a much higher temperature (248° F.), but it is preferable to commence at the lower degree and gradually raise it. Slight massage should follow each *seance*. By this treatment the effusion in the joint is quickly absorbed. Hydrarthrosis of rheumatic origin, however, does not benefit from this method as much as that due to traumatism.

TUBERCULOUS GANGLIA IN CHILDREN.

When the ganglia have not yet suppurated they can be treated locally by compresses of some warm absorbent solution and renewed every three hours

Spirit of camphor, 10z.
Lead lotion, 2 oz.;

or

Chloride of sodium, 1 oz.,
Water, 1 quart;

or

Tincture of iodine, 15;
Sulphate of magnesia, 4 drachms;
Chloride of sodium, 1 oz.;

Water, 6 ozs.

The compresses will be applied in the daytime, and at night the following ointment:—

Carbonate of ammoniac, 1 drachm;
Camphor, 2 ozs.;

Axunge, 1 oz.

As soon as fluctuation is observed, an exploring puncture should be made and the pus replaced by injections of iodoform and ether (10-100). These injections are repeated every 10 or 15 days.

In case of larger cold abscesses, oxygen water should be injected, after removal of the pus, once a week. The usual medical treatment will not be neglected.

TREATMENT OF CIRRHOSIS OF THE LIVER.

Prof. Huchard recommends the following treatment for cirrhosis of the liver:—

Milk diet continued for a month; a glass of ordinary milk every two hours and one glass of skim milk morning and evening. As medical treatment, sulphate of soda will alternate with calomel. A teaspoonful of sulphate of soda every morning for eight days, replaced the following eight days by half a grain of calomel.

Each evening he recommends a compress of cold water covered with oil silk and cotton-wool, over the hepatic region, and kept on all night. When no albumen is present, which is generally the case, small blisters are applied to the liver every ten days. By their means the meteorism diminishes and the patient expresses himself as distinctly better.

Another method frequently employed is *massage*. It increases the diuresis and helps to remove the ascites.

The following ointment facilitates the manoeuvre of massaging:—

Spirit of juniper, 1 drachm ;
Lavender spirit, 1 drachm ;
Lanoline, 5 drachms ;
Vaseline, 5 drachms.

Diuretics have but little effect on the ascites; nevertheless theobromine might be given.

Theobromine, 10 grs. ;
Phosphate of soda, 10 grs. ;
For one wafer.

Three daily, at one hour's interval between each, for three days.

If the liquid continues to increase, in spite of treatment the patient must be tapped, and the operation renewed as frequently as may be necessary.

As to complications, the most frequent is epistaxis, for which the usual treatment is generally sufficient. However, in grave cases, applications of senna and gelatine will be found very serviceable.

Chloride of sodium, 5 grs. ;
Gelatine, 1 to 2 drachms ;
Water, 3 ozs.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, July 16th, 1905.

At the Medical Society Hr. Bickel related the result of his experiments on dogs relating to the INFLUENCE OF ALKALIES AND ACIDS ON THE SECRETORY FUNCTION OF THE STOMACH.

A fistula was made into the stomach of a dog, and the effects of both alkalies and acids noted. Contrary to the general view, he found that alkalies, and especially bicarbonate of soda, not only reduced the acidity of the stomach, but also restrained or diminished the secretion of gastric juice, either from its paralysing effect on the cells, or through its alkalisating action on the blood. Hydrochloric acid increases the secretion of gastric juice, and its effects in this direction lasted a considerable time.

Hr. Ewald suggested that the diminishing action of bicarbonate of soda on the secretion of gastric juice did not require a hypothesis of alkalisation of the blood; the action was more likely to be a reflex one.

Hr. Senator followed with a paper on

SUBCUTANEOUS INJECTIONS OF PREPARATIONS OF IRON AND IRON AND ARSENIC.

He said that the subcutaneous incorporation of iron had never yet gained a footing in therapeutics. Recently, however, attention had again been drawn to it on the initiative of Italian physicians. It was to be observed that some easily soluble preparation of iron did not cause that severe pain after injection that had hitherto rendered this method of treatment impracticable. Then the green ammonio-citrate of iron in 10 per cent. solution could be given, commencing with half a syringeful a day, and gradually increasing the dose to a syringeful. If continued for from thirty to forty days cases of chlorosis were said to be cured.

According to his own experiments in the cases of chlorosis and simple anæmias, the method had no advantage over administration by the mouth. It had been stated, as in favour of injection, that the iron was not absorbed through the intestinal canal; this was completely contradicted; both organic and inorganic preparations of iron were sufficiently absorbed through the intestinal walls. The iron was found deposited with marrow of bones in the spleen and in the liver. (2) It was badly borne, and led to gastric catarrh. That was true for a small proportion of cases; the gastric catarrh was, however, often a consequence of the existing anæmia, and disappeared after its removal. It was also an old-time rule to remove the disturbance of digestion before beginning the iron treatment (hydrochloric acid). (3) Iron was more readily absorbed from the connective tissue than from the stomach. This, however, was not in favour of the subcutaneous method, but against it. Iron was only given in chronic diseases, whether it was absorbed

rather more rapidly was, at the least, indifferent, certainly not an advantage, for iron was a poison that in large doses could produce serious mischief in the organism. No such consequences had been observed when it had been given by the mouth, but they had after subcutaneous injection. (4) It had been stated that patients took iron very unwillingly; there were now, however, a number of well-tasting iron preparations, and to have an injection made day after day for weeks and months were not among the agreeables of treatment. From the foregoing it followed that the treatment by subcutaneous injection was only suitable in innocent and malignant ulceration of the stomach, in pernicious anæmia, leucæmia, and pseudoleucæmia, where the stomach would not bear medicines, and also, perhaps, in the hæmorrhagic diathesis. He had made use of this form of treatment in about thirty cases such giving an iron-arsenic preparation, and especially the readily-soluble ferr. arsen. ætric. ammon., in order to have the advantage of the arsenic. He had also used the cacodylate of iron. In four cases carefully observed, there was, after some time, a considerable increase in the erythrocytes and of the hæmoglobin. Of course, in the diseases named there was no question of recovery.

Hr. Frank had used it with good results in eight cases of chlorosis and anæmia. He had used the ferr. cacodyl. The great pain observed after subcutaneous injection was not present nor the garlicky smell.

Hr. Ewald had had good results from using iron in suppositories. He gave up ferrum lacodylicum on account of its fearful garlicky smell.

Hr. Senator also rejected the cacodylate preparation for subcutaneous injection, both on account of its great painfulness and its garlicky odour. He had not injected iron into the veins, fearing a possible clotting of the blood.

At the Society of Charité Physicians, Hr. Heubner showed a case of

OBLITERATING PERICARDITIS.

This disease, in fatal cases of articular rheumatism in childhood was the one that was the cause of death. During late years all the children dying in his wards of acute articular rheumatism (seven in number) had obliterating pericarditis. It either developed some weeks after the rheumatism had ceased, progressed slowly, was often complicated with pleurisy, and led frequently and unexpectedly to cardiac weakness and death or the commencement of the course was so hidden that the disease was first recognised at the autopsy. A third, also obliterating form, was the tuberculous. Of importance in difficult diagnosis was the striking influencing of the pulse by the breathing as a "feathering" of the wall of the thorax (demonstration) at each diastole. Possibly the operation of cardiolysis would be of value.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, July 16th, 1905.

SUBPHRENIC ABSCESSSES.

At the Gesellschaft der Aerzte, Ranzi exhibited a few cases, with a report on ten more whom he had operated on between April, 1901, and July, 1904. The primary origin of these cases, as far as could be obtained, was: Three from diseased appendix, four were the result of gastric troubles, one was due to an ulcer in the duodenum; another was from a tubercular ulcer of the ascending colon, and the last from some cause unknown. With only two exceptions, all of the abscesses occurred on the right side in the intra-peritoneal folds. In nine of the cases the matter formed between the liver and the diaphragm, and in only one case was it found between the spleen, colon, and diaphragm. With respect to the formation of gas, this seems to be according to the rule given in textbooks, as five of the cases accorded to Leyden's description of the disease, pyo-pneumothorax subphrenicus, while others describe the disease as pyothorax subphrenicus, or empyema-hypophrenicus.

The diagnosis was a more difficult matter, although we must recommend it as secondary from some other inflammatory centre, such as typhlitis, appendicitis, pleuritis, &c., but the most common origin given in books is gastric, which was not the rule in the ten cases just presented. The lowering of the liver and raising of the lungs with fever, and difficulty of respiration would justify the use of the exploring needle as a confirmatory test. Leyden recommended the use of the manometer to test the abdominal pressure for inspiration and expiration, which was greater in the former and less in the latter than the normal. If the chest were tested in the same manner the results would be opposite. The whole history must largely guide the careful clinician. The treatment recognised is generally operative, and although the prognosis given in books is bad, and fixed at 35 per cent., the ten cases recorded had only two deaths, or 28 per cent.

There are two methods of operating which may affect results—*viz.*, "Gruneisen's perpleural," or the abdominal. The former is not free from infectious complications, and was rigidly avoided in all these cases with the exception of one where secondary infection had already occurred.

Hochenegg and Schnitzler gave their experience, and concurred with Ranzi that the "perpleural" operation should be rigidly avoided.

CRETINISM.

Knoepfelmacher presented three sisters, the eldest, *æt.* 15, to show that the disease is hereditary as well as sporadic. The eldest is 100 centimetres long, or 30·37 inches, has myxœdema over the face and supraclavicular spaces; a dry, scurfy fold skin over the backs of the hands and instep of the feet. The four-year child had ossification in many bones, as shown by the Röntgen rays; speaking short expressions with a drawling monotone and rather coarse voice; apathetic, indolent and mentally defective.

The six-year-old brother is 81 centimetres, or 31·83 inches; upper and lower limbs equally long; the thyroid palpable; no decided myxœdema, but disturbed ossification according to Röntgen rays.

The youngest of the family, *æt.* 1½, fontanelle open; hand, short and plump; the skin dry and scurfy, while the child speaks in syllables and in monotone; it appears indolent, imbecile, and falls down with a plump.

The third, *æt.* 2½, 68 centimetres long, or 26·77 inches; fontanelle wide open; cannot walk, speaks little, and lies with the mouth open, and the tongue between the four teeth he has, while the skin is dry and scurfy. The parents of the children are Viennese, having been born and brought up in the city which they had left only a few days on a holiday. Their fathers before them were also brought up in the town, and no trace of consanguinity can be observed. The other children of the family are healthy, and no sign of thyroid or any other disturbance can be perceived. We must therefore conclude that these three cases are sporadic infantile myxœdema.

It is worthy of note that there is present a family hypothyroidism, although there is a tendency to goitre formation, which is not common in sporadic cretinism, as well as a want of distinct myxœdema in two of the cases.

Eiselsberg asked what his line of treatment was in all these cases?

Knoepfelmacher replied by saying his first form of treatment was the usual products of the thyroid gland substance given internally, but later on he resorted to Christiani's implantation of small pieces of the gland in the body of the patient.

Operating Theatres.

GREAT NORTHERN HOSPITAL.

OPERATION FOR SUPPURATIVE APPENDICITIS.—Mr. PEYTON BEALE operated on a youth, *æt.* about 14, who had been admitted with the following symptoms: Temperature 99, pulse about 130, suffering from diarrhoea, tongue very furred, pupils dilated, sweating

freely, the sweat, together with the breath, having a distinctly fœcal odour; abdomen of normal aspect, resonant over the front and dull in each flank; no difficulty of micturition, nothing abnormal on rectal examination. The patient complained of pain all over the abdomen, but on careful investigation it was quite clear that this pain was neither in the skin nor in the abdomen, and on further examination it proved to be in the muscles, not only in those of the abdomen, but in all the voluntary muscles, so that pain was elicited when any of the muscles were tapped, and with the pain there was marked sudden contraction. The skin was really anæsthetic. As regards the previous history of the patient, eight days before admission, on returning home from a bicycle ride, he was seized with abdominal pain, referred chiefly to the umbilicus; he also had some diarrhoea, which continued for two or three days together with some vomiting, the vomit being stained with bile. The medical man who saw him supposed him to be suffering from ptomaine poisoning. By the fourth day after the onset of the symptoms the boy appeared to be practically well and free from pain, but the symptoms which were found on his admission to the hospital came on suddenly in the early morning of the day on which he was admitted. Mr. Beale considered that the case was one of ulceration of the appendix with perforation and general peritonitis of probably six or seven days' duration, and he operated at once by cutting down in the right iliac fossa. On opening the peritoneal cavity a large quantity of exceedingly foul pus escaped; a large concretion was lying loose and was picked out. The appendix was found, its distal, two inches, being quite normal, but the intervening portion between it and the cæcum had ulcerated away completely, leaving a ragged rent in the cæcum from which fœcal matter was escaping. The mesenterus holding the distal part of the appendix was ligatured, and the latter removed. The cæcum was pulled out of the wound, a number of adhesions being broken down to bring this about, the hand was then introduced into the peritoneal cavity, together with the end of a rubber tube attached to a steriliser containing hot sterile salt solution. The whole of the peritoneal cavity was next washed out rapidly, large quantities of pus being dislodged from the pelvis and from beneath the liver. The wound was then packed with large plugs of gauze so inserted as to prevent the cæcum from slipping back, and the wound was dressed in the ordinary way.

Mr. Beale remarked that this was a typical case of a variety of suppurative appendicitis which was, happily, very uncommon. In dealing with over 250 cases of localised or diffuse suppuration due to a lesion of the appendix he had only come across four or five of this variety. The peculiarity of the symptoms was due to a very extensive absorption of the poisonous toxin or toxins produced by the *Bacillus coli* into the blood stream, and this it was which produced the anæsthesia of the skin, the hyperæsthesia, and irritability of all the voluntary muscles—in some respects resembling strychnine poisoning—the dilatation of the pupils, and the noxious odour of the breath and sweat. In none of the four or five cases of this kind that he had seen and immediately operated upon were there any of the typical signs of suppurative appendicitis—they were masked entirely by the toxæmia—but in every one there was a history of a typical attack of appendicitis about seven to nine days previously, and which had, apparently, passed off, leaving the patient

so well that in some cases he was able to resume his work, only to be seized a few days later by the symptoms such as are described as being present in the case he had just operated upon. In order to emphasize the class of symptoms, he mentioned the following as the first of this type of case which he had seen: Some years ago he was called to see a young man, æt. 21, living about six miles out of London, whose immediate symptoms were slight pain over the bladder, some impairment of memory and inability to fix the attention, muscular pains all over the body with spasmodic muscular twitchings constantly recurring, breath and sweat both had a noxious fæcal odour; the patient was constantly getting up and walking about the room, and was feeling on the whole fairly well. He had walked to his home from the City (six miles) that very day, but was seized with an attack of syncope soon after his arrival; his pupils were dilated and he was sweating freely. His previous history was interesting, for just a week before he suffered from a typical attack of appendicitis which kept him in bed for three days only, and from which his doctor believed he had completely recovered. Mr. Beale did not at that time realise the gravity of the man's symptoms, and gave a good prognosis after administering an enema with a very good loose action. This patient went to sleep at 12 o'clock the same night, woke up suddenly at 3 o'clock in the morning, ran round the room in a state of delirium, and dropped down dead on the floor. At a *post-mortem* examination next day, at which Mr. Beale was present, the abdomen was found full of pus, and the appendix ruptured and practically ulcerated away; the appearances rendering it quite certain that the rupture had occurred many days previously. Mr. Beale also referred to another case, which was perhaps still more striking. This was a lady, æt. 60, who was living on the coast of Devonshire and who had been treated one week previously for a typical attack of appendicitis which had subsided. The patient did not, however, feel perfectly well; she was of a very energetic temperament, and on the morning of the day on which Mr. Beale saw her she had actually walked three or four miles and bathed in the sea. She reached home with some difficulty on account of shortness of breath and irregularity of the heart's action, both of which she ascribed to a little indigestion. When Mr. Beale saw her about three hours after she had walked home she had a temperature of 100°, dilated pupils, very feeble rapid pulse, was sweating profusely, and slightly distended abdomen, absolute dulness in both flanks with emphysema beneath the skin all over the cæcum and ascending colon. An incision was immediately made in this region, and the abdomen was found full of pus with very large collections in the pelvis and beneath the hepatic flexure of the colon. Two concretions from a ruptured appendix were found free in the pelvis, and it was quite evident from the ulcerated stump, which was the only portion of the appendix left, that the rupture had occurred many days previously. This patient, therefore, had been walking about freely for several days with a ruptured appendix and her abdomen full of foul pus, and yet, although she was seen daily by a thoroughly capable medical man, he could discover no symptoms which could be regarded as serious. At the same time he admitted that he felt uneasy about the patient, but could not induce her to remain quiet in bed. From Mr. Beale's experience from these four or five cases, he considered that the only safe plan was to keep a patient who had suffered from an attack of appendicitis perfectly quiet for at least a week, after all acute

symptoms had subsided, and that the patient's friends should be warned that danger from the attack had not passed away, and that an operation might still be necessary at a moment's notice. In his opinion, if there was the very slightest doubt, there was far less risk in opening the abdomen over or behind the cæcum and exploring than in leaving the patient alone.

The case operated on at the Great Northern Hospital reported above is still doing fairly well eight days after operation, but this was the only one of this type which he, Mr. Beale, had known to progress favourably after operation.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, JULY 19, 1905.

DR. DOYEN DISCOURAGED BY THE PARIS COMMISSION.

EVENTS travel apace. A week ago we noticed in our leading columns the remarkable Report of the Cancer Research Association. In that notice a comparison was made between the patient logical methods of scientific investigation therein recorded and those of a French surgeon, who had established a kind of branch practice in London for the treatment of cancer on theoretical lines. The commercial side of that extraordinary new departure in international medical amenities was most unpleasantly apparent in the fact that the pamphlets of the surgeon in question were translated into many languages. Furthermore, in a recent notorious trial in France, it was shown that enormous fees had been charged to an American patient for treatment by a special serum prepared in accordance with uncorroborated theory and experiment. Dr. Doyen, before invading London, might at least have waited for the result of the scientific committee of inquiry appointed by the French Academy of Medicine. The report of that committee has now been issued, and if we are to believe the advance reports that have reached our shores, the whole fabric of Dr. Doyen's creation has been shattered, and shown to be worthless from one end to the other. This

exposure will bring small comfort to the over-credulous persons who have been led by his unsubstantiated statements to pay large sums for treatment. It will, of course, be at once obvious to all who are acquainted with formal scientific methods that Dr. Doyen has acted in good faith, and that his erroneous conclusions were the result of faulty observation rather than of deliberate and cynical irresponsibility. Indeed, were it not for the too-assertive commercial aspect of the matter our sympathies would be cordially extended to Dr. Doyen as an enthusiast whose energies had induced him to overshoot the mark. As things stand, however, it is hardly possible to absolve the Paris surgeon from responsibility. Before he announced to the world the discovery of the specific pathogenic organism of cancer in the shape of the so-called micrococcus neoformans he should have taken every possible precaution to have had his observations controlled by independent workers. Had he done so, he would have been spared the mortification of subsequent exposure by the Paris Academy. We cannot conceive a more unhappy position than that of a medical man who has received large sums of money on the strength of alleged discoveries that would not survive an ordinary scientific investigation. The whole affair, indeed, presents a painful picture of the man of science who is led into untenable positions because of the faultiness of his intellectual methods. That the cause of cancer and its consequent cure will one day be discovered can hardly be doubted in the light of the faith created by the marvels of modern science. It is to be hoped, however, that when the good news comes it will bring good to all humanity rather than fabulous wealth to the coffers of any single human being. It will be a sad day for the honour and dignity of medical science when it adopts the methods of the modern man of business, who must become rich at all costs. The history of Dr. Doyen's campaign is soon told. He isolated an organism, the micrococcus neoformans, which he pronounced to be the specific pathogenetic organism of carcinoma. With the aid of cultures of this microbe he produced a serum with which he claimed to be able to cure cancerous disease in human beings. The French Academy of Medicine ultimately appointed a Commission of five eminent members to test his claims. Twenty-four patients were produced by Dr. Doyen, and treated by him under the scrutiny of the Commissioners. Of these patients several died, the greater number grew worse, some remained stationary, but no single instance of cure is reported. More than that, the report states that not one of the twenty-four patients experimented upon in all these months has derived the slightest good from the new treatment. The following sentence from Dr. Delbet may be quoted: "Nothing whatever has been observed in the examination conducted by Commission to justify us in saying that Dr. Doyen's treatment is in any way beneficial to

patients suffering from cancer." And thus is pricked another bubble reputation.

VACCINATION POLICY.

THERE are some tenets of the faith medical which it is as dangerous to impugn or to criticise as any of the faith theological. This is more easily comprehensible than justifiable. It is comprehensible that after warm discussion and re-terminations have raged round a question, opponents are apt to resent interference with any *modus vivendi* that may have been patched up between them; but when the opponents on one side are medical men, it is only to be expected that their superior intellectual training will give them grace to listen carefully to any new light on the subject, even if need be to the extent of suffering fools gladly. The question of vaccination has been, and still at intervals continues to be, a subject of much feeling. It is only natural that when a preventive measure of practically absolute efficacy has been discovered and freely given to humanity medical men should feel not only hurt at the ingratitude of those who reject it with scorn, but impatient with the pettifogging sophisms and pinchbeck arguments with which its rejectors support their opposition. To any man who has had experience of small-pox, and, indeed, to any man whose mind is open to reason, the protection afforded by recent vaccination is the most self-evident phenomenon in a world of chimeras. Only the hopelessly ignorant or the hopelessly prejudiced would venture to doubt it; no amount of fresh evidence could upset the experience of the past that so far as efficient, recently performed vaccination as a prevention of small-pox is concerned, the question is no longer a question; it is a *chose jugée*. The anti-vaccinationists never tire of taunting present-day advocates of vaccination with the mistake made by the early vaccinationists in thinking that the protection afforded by vaccination was life-long. Rhetorically, such reproaches enjoy a certain success; but they do nothing to further the elucidation of truth. All observers of small-pox are aware that although the protective influence of vaccination is all but absolute for several years after a successful operation, the protection gradually lessens as time passes, until it is barely, if at all, traceable in old age. Consequently the Acts that have made the vaccination of infants compulsory, have had the effect of altering the age-incidence of small-pox in the community, so that the disease when it appears in well-vaccinated communities, now affects persons in adolescence and middle-age rather than the young. The Acts have had this effect, but they have not eliminated small-pox from the country, nor is it scientific to expect that they will. Besides the unvaccinated, there remains a large susceptible vaccinated population, and this factor can be eliminated only by stringent re-vaccination, and if we may use the expression, re-re-vaccination. Now in discussing a matter of this kind, it is necessary wholly to dissociate the medical

question of the efficacy of vaccination—which no reasonable man disputes—from the political question of how the community is to be secured from the dangers of small-pox—which many unreasonable people dispute bitterly. The medical profession have done their duty faithfully in urging that the only complete safety lies in universal vaccination and re-vaccination, and the country as a whole have rejected the policy. With regard to primary vaccination, a serious loophole is created by the refusal of many people to have their children vaccinated, and recently the Government have announced that they propose to take no steps with regard to re-vaccination. It may be taken for granted that the Liberal party, if they come to power at the next election, are even less likely to make any move of the kind. The point, therefore, remains—how far partial primary vaccination is protective to the whole community? It has been pointed out more than once, and the fact receives illustration in every outbreak of small-pox, that a good deal of the dissemination of the disease is carried on by mild cases of the disease occurring in vaccinated persons, who are not sufficiently ill to seek advice. In this way the good done by primary vaccination in protecting children is to a certain extent counteracted by the harm done by the vaccinated adults, and the assessment of this factor is a point of grave importance. Moreover, there remains the reflection that a great deal of the stupid, unreasoning prejudice against vaccination is due to the compulsory character of the vaccination laws, for despite the conscience clause, vaccination is still more or less compulsory, and the effect of the old severe and the new benign compulsion are still powerful elements in stiffening the necks of the anti-vaccinationists. Those who are watching the newer phases of the vaccination question will be interested to read the report on the small-pox epidemic of 1904 at Leicester recently presented by Dr. Killick Millard, the medical officer of health for that borough. Leicester is a notoriously badly vaccinated town, and its small-pox future has been mapped out for it in gloomy terms; but though it has passed through outbreaks in 1903 and 1904, the methods adopted by the sanitary department have been remarkably successful. In the former year 394 cases occurred with 21 deaths, and in the latter 321 cases with but four deaths. A vigorous policy of isolation, disinfection, and vaccination of contacts has been pursued, and whether by good-luck or good management, the results have proved surprisingly at variance with the predictions of the past. In making itself the *corpus vile* on which a gigantic experiment in public health may be performed, Leicester is obligingly doing for itself what no one would have suggested should be done to it, but there is no denying that if with an efficient staff and a complete modern organisation it is able to cope with all future outbreaks as successfully as with those of 1903 and 1904, it will take out of the criticisms that have been levelled at it much of their sting.

But many years must yet elapse before the experiment can be held to be complete.

THE TEACHING OF OPERATIVE SURGERY.

THE traditional method of teaching operative surgery by the actual performance by the student of operations on the dead body has much to recommend it. It has the great advantage of forming a connecting link between the dissecting-room and the hospital theatre, while it impresses on the student the fact that all surgical procedure is based on anatomic knowledge. It allows him to recognise structures in a similar condition to that in which he is used to them in the dissecting-room, although he approaches them from a different stand-point. As long, too, as surgical operations were performed only along the lines of certain "classical operations," a student could gain knowledge of the special method required for each operation by work on the *cadaver* better than by any other means. In pre-anæsthetic days, when speed was of the utmost importance, a precise knowledge of the steps of a proposed operation was a matter of greater moment than at present. Nowadays, however, a somewhat different kind of knowledge and skill is required in a surgeon, and it must be admitted that a course of operative surgery on the *cadaver* alone is not sufficient in giving the necessary knowledge of operative procedures. The most important part of surgical technique at the present day is not the use of the hands or of the tools, but the thorough practice of asepsis. So far from helping to a knowledge of aseptic methods operative work on the dead body carries with it necessarily an entire disregard of surgical cleanliness. The success of a surgeon nowadays depends, not on his performing a "neat" operation, but on his knowing how to prevent sepsis developing in his wounds. Moreover, with the freedom given by aseptic methods and the use of anæsthetics, but little regard is paid to the classical methods. An operator does not proceed by cast-iron plan, but he gives himself leave to change his road to the desired end should he think it advisable so to do in the course of operation. Every man is, in fact, a law unto himself. Under these circumstances it is obvious that the traditional method of instruction has not the same value at the present day as it possessed a generation or two ago. It emphasises points which are gradually losing their importance, while it entirely fails to supply certain requirements of modern surgery. With the view of remedying these defects, and of accustoming students to the manipulation of living tissues, some of the American schools, notably that of Johns Hopkins, have adopted the method of supplementing instruction on the *cadaver* by a course of what is termed "comparative surgery." This is, in fact, a course of operative surgery on the lower animals, the treatment of each patient being as closely as possible assimilated to the surgical treatment of human beings in hospital. Clinical histories are kept on regular hospital sheets; the effect of the

anæsthesia on pulse and temperature are noted; pathological notes and post-operative facts are recorded; and where death occurs, a careful autopsy is performed. Measures are taken to protect against sepsis just as strictly as in the case of human patients, and notes are kept of the steps adopted to procure cleanliness both of operator and of patient. By operating under such circumstances a responsibility is added which is entirely absent if operations be only on the *cadaver*. The student, in dealing with a living patient, has to look forward to the progress of the case as his justification or condemnation, just as in the case of a human being. Moreover, on a living subject—and on a living subject only—can he learn, let us say, how to deal with hæmorrhage, or how to protect an abdominal cavity from infection. There are, however, obvious difficulties in adopting the method in these countries. The difficulty of obtaining sufficient material, and the obstacles imposed by the laws regulating vivisection, place a formidable though not an insuperable bar in the way. In America, similar difficulties were at first met, but as time went on, at Johns Hopkins Hospital, at least, a most pleasing solution was found. Learning of the work, the owners of animals suffering from surgical diseases, which in many cases veterinary surgeons are loth to operate on, have begun to bring them to the surgical teachers for operation, with the result that there is now promise of an animal clinique which may furnish material sufficient for teaching operations. That thoroughly sound work is done from the points of view of both student and patient, is shown by the careful records of cases published in the official journal of that institution.

Notes on Current Topics.

Taxation of Scientific Instruments.

As to whether Protection or Free Trade be the better State policy, we are not prepared to offer an opinion, but to men of science, at any rate, there are certain advantages in living in a country of free imports. For instance, we in this country have great advantage over our American colleagues in that scientific instruments are not subject to a heavy tariff. There is, for instance, in the United States a heavy import duty on microscopes, with the result that purchasers must either pay a very high price for an inferior instrument to an American maker, or pay an enormous tax on a European article. Nowadays, when microscopes are a necessity for every intelligent physician, a law like this acts as a serious bar to the progress of the scientific knowledge of medicine. A peculiarly hard case of the application of this law has lately been made known by Professor Councilman in a correspondence published in the American journals. A medical man, a pupil of Dr. Councilman's, 1902 had bought a Zeiss microscope, paying full duty thereon on its arrival in America. In 1904, he brought the instrument with him to Manila, and while there, one of the

lenses requiring repair, he despatched it to Jena. It has now been returned to America, but is held in Boston Custom-house for a duty of fourteen and a half dollars. As the original cost of the lens was about thirty-five dollars, it is now perhaps worth some twenty-five, and Dr. Councilman, drawing attention to the hardship of the case, has appealed to the United States Treasury for remission of the duty. The Treasury officials, however, decline to afford any relief, quoting the law that "dutiable merchandise imported, and afterwards exported, although it may have paid duty on the first importation, is liable to duty on every subsequent importation."

Ambulances for London.

WE are glad to see that the long promised Ambulance Scheme of the London County Council has at last been produced. The Council propose to begin in a small way, and the scheme generally suggests an amount of self-diffidence that is rather surprising. Londoners are in earnest about having some ready and useful form of aid for street accidents, and they have waited for it far too long already. The County Council propose to erect one principal and seven district stations, to which access may be obtained by street calls similar to those used for the fire-brigade. At each station there will be a motor ambulance, and two or three men trained in first aid. One of the men is to be married, and the wife is to keep house for them all. At the principal station there is to be a superintendent of the whole service, five ambulance drivers, and servants. After the scheme has been approved by the Council, parliamentary powers will have to be sought, and we hope there will be wide enough scope to admit of an extension of the very modest proposals now put forward. Eight stations for the whole of London cannot be regarded as excessive, for it must be remembered that the utility of such a service depends on the needful assistance being obtainable at a few minutes' notice. If injured people have to lie in the streets while the ambulance is summoned from a distance of some miles, it is not improbable that serious complaints will be made. It is to be hoped that power will be sought to inflict severe fines on people who summon the ambulances needlessly, or for slight causes, as they might easily be kept racing about all day to attend to the cuts and bruises that are daily sustained by wayfarers. We notice that, as might have been expected, there is to be no recourse to medical advice; first aid proficiency being deemed all that is essential to equip an uneducated man to deal with the gravest emergencies in the streets of a vast city.

A Dust-arresting Respirator.

THE discovery of a trustworthy dust-arresting respirator for the use of those engaged in dusty trades would be of considerable importance to public health. That we are not within easy distance of such discovery would seem to be shown

by the failure of the Society of Arts to receive any satisfactory response to their offer of a prize for such an apparatus. It will be remembered that a couple of years ago the Society offered a prize for the best dust-arresting respirator, and the decision of the committee of adjudicators has recently been published. (a) It appears that no less than sixty applications for the prize were received, of which thirty-three, or more than half, came from abroad. Out of the entire number the committee have failed to find any which they could recommend for a prize. This is not perhaps matter for wonder, as we hardly think the genius of an inventor is likely to be much stimulated by the offer of a prize, and if there had already been any trustworthy apparatus it would have been known. Among so many appliances offered, there was, of course, great variety of device, but most of those of any promise, in the eyes of the committee, were respirators of the bag type, furnished with a pad of some sort to arrest dust. In nearly all, however, the air passages were insufficient, and the use of the instrument would be exhausting to the wearer. While the enterprise of the Society of Arts has hardly done much to prevent the inhalation of dust, it has, in another sense, cleared the air, as it has shown that while there are many useful respirators in actual employment, there is none which can be regarded as entirely trustworthy and convenient.

Louis XI.'s Physician.

THE monarch of old had a sharp and effective way of dealing with those of his courtiers and servants from whom he disagreed, and the physician who wished to retain his post as attendant to the Court had to tread warily among the pitfalls that beset his path. It is not surprising therefore, that many a Court physician became something of a sycophant, and it is pleasing to read of one, at least, who retained his independence, even if the means he used were not those that would commend themselves to the practitioners of to-day. Louis XI. is notorious as having been one of the most fickle and untrustworthy kings in history, and especially towards the end of his life, was constantly dismissing his attendants and clapping his courtiers into prison or subjecting them to torture. The only officer whose influence over him never wavered was his physician, Dr. James Coctier, who not only demanded exorbitant fees for himself and good appointments for his friends, but treated the King with a *sang froid* which amounted almost to contempt. Comines records of him that in Louis' last illness he charged him 54,000 crowns in cash for his services, obtained the Bishopric of Amiens for his nephew, and other great offices and estates for himself and his friends. "Yet this doctor used him so scurvily, one would not have given such unbecoming language to one's servants, as he gave the King, who stood in such awe of him he durst not forbid him his presence." Coctier's influence seems to have rested in a

(a) *Journal of the Society of Arts*, June 9th, 1905.

threat to the King, that if his Majesty dismissed him as he had done many other officers, he (the King) would not live eight days. So terrified was Louis that he followed Coctier's injunctions to the letter, and to the chagrin of his followers, continued to flatter his physician, who fawned upon him: "which," adds the historian, "must needs be a great mortification to a Prince who had been obeyed all along by so many brave men much above the doctor's quality."

Dermic Malingering.

THE literature of malingering is by now fairly large, though for the most part scattered and not easily accessible. An interesting account of a rather rare mode of malingering—the production of skin eruptions—has recently been published by Dr. Heidingsfeld of Cincinnati (a). As with other forms of malingering the subjects most affected belong nearly altogether to one of two classes, men who wish to escape work or military service, and hysterical young women. All Dr. Heidingsfeld's patients belonged to the latter class, the assumption being that the motives actuating the former class are absent in happy Cincinnati. Feigned eruptions can for the most part, be recognised by their peculiar form, unlike any known lesion of disease, and by their localisation to parts easily accessible with the right hand. In many of the cases, although there was no doubt as to the diagnosis, it was found impossible to discover the means by which the lesions had been produced. In two, for instance, the left arm was marked by very regular excoriations a couple of inches long by half an inch broad, such as might be produced by rubbing with a piece of glass; warning the patient that the nature of the disease was known prevented the appearance of any further lesions. In another very peculiar case the lower limbs were found studded with superficial abscesses. Careful examination revealed that each abscess contained a pin or needle, and in all, some hundred pins or needles were removed from the patient. The motive in this case was self-torture on religious grounds. The importance of being able to recognise self-inflicted lesions of the skin is very great, as in some of Dr. Heidingsfeld's cases, heroic measures had been advised by other physicians before the true nature of the case had been recognised.

Another "Bloodless Surgeon."

THE Medical Defence Union have added another to their long series of successful prosecutions against offenders under the Medical Acts. The defendant was in individual named Walford Bodie, of Arundel Street, Leicester Square, who masqueraded at the Camberwell Palace of Varieties and other music halls as "the Bloodless Surgeon." In this capacity he did "turns" which consisted in treating by mesmerism, hypnotism, and magnetism, people "given up" by other surgeons. We are not sure that even a metropolitan magistrate might not hold the description "Bloodless

(a) *The Lancet*, April 29th, 1905.

Surgeon" to be an offence against the Acts—certainly the use of the word "surgeon" would be sufficient to do so under an ordinary reading of the law—but "Dr." Bodie made the assurance of his conviction doubly sure by having the letters "M.D." appended to his name. Mr. Avory, who defended, put forward the excuse that the initials "U. S. A." should have been added to those of "M.D.," as Bodie possessed medical degrees in America that entitled him to use the letters "M.D." and "C. M." It should be well-known that there is no University in America that can be described by initials as "U. S. A." any more than there is any English University that can be described as "Eng." Any diploma purporting to allow a man to practise medicine under the description "M.D., U.S.A." would be as worthless for State purposes in America as it would in this country. The magistrate, Mr. Francis, agreed with Mr. Avory that the case was not one that called for a heavy penalty, and inflicted a fine of £5 with £5 5s. costs. We wonder if Mr. Francis would consider it a bad case if some adventurous spirit were to describe himself as a "Barrister-at-Law," and appear on the stage of second-class music halls to give displays of his forensic cunning.

Singular Death from a Blow.

A CASE of much medico-legal interest was investigated last week by Major Arundel, coroner for Pontefract. The inquiry was held upon the body of Arthur Wilson, aged 16, a stonemason's apprentice. The evidence of the boy's friends showed that on the evening of his death, deceased and others met a boy of twelve named Herbert Gardham, who had been fishing and had a rod in his hand. Wilson and Gardham began to quarrel, and after Wilson had struck Gardham several times with his fist, Gardham retaliated and struck Wilson across the region of the stomach with the fishing rod. Wilson stood for a second with his hand upon his stomach, then dropped to the ground, and died after gasping once or twice. Dr. Rigby, who was called immediately, said that he tried artificial respiration for an hour, but without avail. He had made a post-mortem examination of the body, and found all the organs healthy and quite normal. There were no external marks beyond a bruise upon the right shin about the size of a sixpence. None of the abdominal organs were in the least diseased. Witness was of opinion that death was due to syncope consequent upon the blow. He did not think it was due to excitement. A heavy blow such as might have been given from the fishing rod produced would probably cause a reflex action from the nerves of the stomach to the nerves of the heart, which would cease beating at once and death would be instantaneous. This would especially be the case if the blow were unexpected and the stomach full of food, as was the case. In reply to a question he thought the deceased could not have been expecting the blow where he got it, or the abdominal walls would have become rigid and probably

there would have been no evil result. The jury, after retiring, returned a verdict that death was due to syncope consequent upon the blow given by Gardham who, by misadventure and against his will, had caused the death of Wilson.

Damages for Enteric Fever.

THE establishment of the responsibility of property owners for disease arising out of negligence of sanitary matters is clearly of great importance to the community. From this point of view the attention of our readers may be called to a recent case settled in the Derby County Court. The plaintiffs brought an action to recover £70 damages for illness alleged to have been caused by certain sanitary defects in a house of which they were tenants and the defendant was owner. The property in question was one of a block of four cottages, in which drains were conspicuous by their entire absence, and which had been visited by typhoid fever no fewer than four times, with one death. In February, 1904, the premises were condemned by the Medical Officer of Health as unfit for human habitation. Nothing was done by the defendant and the plaintiffs later contracted typhoid fever. The case was tried by a jury, who were called upon to decide a number of questions of fact. The reassuring feature so far as the future of public health administration is concerned lies in the verdict of £24 10s., with costs entered in favour of the plaintiffs. The offence in this instance was aggravated by the fact that the owner of the cottages was Chairman of the Chelmorton Parish Council, a member of the Bakewell Rural District Council, and a member of the Sanitary Committee of that body. No wonder the county medical officer of health is so often hampered in the discharge of his duties.

Dr. Doyen's Serum.

The general bearing of the exposure of the worthlessness of Dr. Doyen's so-called "discoveries" is noted at length in our leading columns. We cannot assume any expression of surprise at the news that the Committee appointed after the Surgical Congress in Paris last January to investigate Dr. Doyen's cancer serum has pronounced it to be a failure. Dr. Doyen's methods are sufficiently well-known to the readers of this journal to need no further comment. Dr. Delbet, who read the report to the Surgical Society, informed his audience that the Committee were unable to satisfy themselves of even the existence of the "micrococcus neoformans," which was supposed to be the bacterium of cancer, and by means of which the serum was prepared. The therapeutic investigation had lasted five months, and twenty-six patients had been under observation! Nothing was noticed in these cases except the "temporary deceptive improvement which usually follows the first use of serums in general." The conclusions formed after watching the twenty-six cases were that twenty were unmistakably worse, two

remained in an unaltered condition, and in one recrudescence had occurred. The other three cases had not been sufficiently long under observation for a definite pronouncement to be made. It would seem, then, that Dr. Doyen's serum is destined in the near future to take its place in the limbo of discarded "cures" for cancer—that is if there be any room left for its reception. It remains to be seen if Dr. Doyen will pursue the plan of establishing a home for cancer patients in London, as we have been given to understand he purposes to do.

A Jenner Centenary.

JULY 4th of the present year marked a somewhat interesting centenary in connection with the illustrious discoverer of vaccination. On that date 100 years ago he was presented with the Honorary Freedom of the City of London. At a meeting of the Court of Common Council on August 11th, 1803, it was resolved that the Freedom of the City should be presented to Dr. Jenner in a gold box, "as a token of their sense of his skill and perseverance in bringing into general use the inoculation of the cow pock." In his reply on the occasion of the presentation Dr. Jenner expressed a hope that the act of the Corporation would counteract those attempts which had been recently made to retard the progress of vaccination: attempts which he boldly declared originated entirely either from ignorance or from prejudice. A hundred years later and the worthy doctor might be using the same words in an address to the Corporation. But his discovery has nevertheless worked a revolution during the intervening century.

A Modern Niobe.

THE readiness with which the average woman gives way to tears on the small provocation provided by the refusal of a new hat or the suggestion that the time is ripe for administering corporal punishment to her erring infant, is only equalled by the promptitude with which the tears cease when the occasion for them has passed. We read in *American Medicine* for July 1st, of a lady of Sioux City whose case forms an exception to this happy rule. The proximate cause of the trouble is not stated, but it appears that for some reason or another Mrs. Kate Wilbourn found cause for weeping; and once opened the flood-gates refused to close. We can imagine the consternation of Mrs. Wilbourn and her friends when they found their efforts at consolation were in vain, but at the time of writing the poor lady had been crying incessantly and uncontrollably for four days, and no advice or treatment had any effect. The patient does not seem to have been particularly unhappy, and she is asserted to be perfectly sane, but of her own accord she presented herself to the Board of Insanity Commissioners and asked to be committed to a State Asylum, for she felt sure the hospital physicians could relieve her. We recently came across the case of a patient who was

so much amused at a joke he heard at a theatre that he laughed and chuckled at it for two years, to the disruption of his domestic happiness and the disorganisation of his professional work. We hope that the subsequent career of Mrs. Wilbourn will be related, for one can only hope her future may not be so dismal as that of the poor creature whom Latona treated so shabbily.

PERSONAL.

HIS MAJESTY THE KING has ordered that three wards in the Military Hospital, Millbank, shall be named respectively "King Edward," "Queen Alexandra," and "Princess Victoria," in commemoration of their Majesties' inspection of the hospital on the 1st inst.

THE first session of the Congrès International des Gouttes de Lait will be held in Paris on October 20th and 21st. The presidents are Dr. Variot, physician to the Children's Hospital, and Dr. Dufour, the founder of the "*goutte de lait*."

KATHARINE COUNTESS OF STAMFORD AND WARRINGTON, whose will has now been proved, left £200 each to the Queen's and General Hospitals, Birmingham; £500 to the Leicester Infirmary in aid of the Children's Hospital; and £100 to Corbett's Hospital, Stourbridge.

A NEW Dental Hospital was formally opened at Birmingham on July 6th by Sir Oliver Lodge, Principal of the University.

At a meeting of the Manchester and District Association of the Fellows of the Royal College of Surgeons of England, held on July 8th, the following propositions were passed: That it is desirable that Manchester be represented on the Council of the Royal College of Surgeons. That Mr. G. A. Wright be requested to stand as a candidate for the next election.

At a quarterly meeting of the Council of the Royal College of Surgeons of England last week Mr. Tweedy was re-elected president and Mr. Henry T. Butlin and Mr. Edmund Owen were elected vice-presidents for the ensuing year.

At the same meeting of the College the following professors and lecturers were elected:—Hunterian Professors: Warrington Haward, A. H. Cheatle, H. J. Paterson, and C. G. Seligmann. Arris and Gale Lecturers: J. H. Watson and Sydney W. Curl. Erasmus Wilson Lecturer: James Sherren.

ON reference to the report from our Edinburgh correspondent in another column, it will be seen that Sir Wm. Muir, the venerable Principal of Edinburgh University, who recently resigned that position on account of failing health, passed away last week, in the eighty-sixth year of his age.

DR. DAVID WALSH will read a paper on the "Cap Film Isolation of Ringworm" at the Public Health Congress held this week at King's College, London.

THE Long Fox Memorial Lecture for this year will be delivered by Dr. E. Markham Skerritt in November.

A REPRESENTATIVE Committee of those interested in the Amalgamation of Medical Societies has been formed of delegates from thirty-seven medical societies.

DR. SINCLAIR of Dundee, is the new President of the Forfarshire Medical Association.

PROF. R. SAUNDBY has been appointed on the recommendation of the Senate, as a delegate to represent

the Medical Faculty of the Birmingham University at the International Congress of Medicine to be held in Lisbon in 1906.

DR. FREDERICK W. PRICE has been appointed Medical Registrar of Westminster Hospital.

Special Correspondence.

[FROM OUR OWN CORRESPONDENT.]

SCOTLAND.

DEATH OF SIR WILLIAM MUIR.

THE venerable Sir William Muir, lately Principal of the University of Edinburgh, passed away, in the eighty-sixth year of his age, on July 11th. He had resigned his Principalship on account of failing health, in 1902, after having served his alma mater for nearly a score of years, but was able to lead his usual life until about ten days ago, when his strength gave way, and though hopes were at first entertained that the indisposition might be merely temporary, he never rallied from it. Sir William Muir was an Ayrshire man, of a respected burgher family. With his three brothers, he was educated for the East India Company's service, and was a matriculated student of the University over which in later years he was to preside in the years 1833 and 1834. More than half a century elapsed, however, before he returned to Edinburgh as Principal—years of strenuous work in India, marked by the high administrative capacity and unswerving devotion to duty which more than justified the honours with which his country repaid him. During the Mutiny he was shut up in Agra, where he acted as head of the Intelligence Department, and was the friend and fellow-worker of the chief actors in that historic struggle; when peace was restored he became Secretary to the Viceroy, and superintended the re-organisation of the North-West Provinces. Thereafter he was member of the Legislative Council, and then Lieutenant Governor of the North-Western Provinces—the ruler of forty millions of men. In 1874 he became Finance Member of Council, and two years later retired from the Indian Service, though from 1876 to 1885 he continued to place at the disposal of the Empire his intimate knowledge of Indian affairs by continuing as a member of the Indian Council in London. In 1867 he was made Knight Commander of the Star of India, and when the Principalship of the University became vacant through the death of Sir Alexander Grant in 1885, the Curators selected Muir as his successor. His eighteen years of office were conspicuous for the hospitality and graciousness with which he presided at the head of the University; his relations with the students were especially friendly, and his influence on them—the intangible influence of an upright, gracious, and tactful personality—was none the less strong that it is difficult to express it in words. By none was the venerable Principal more beloved than by the undergraduates, and no interests were dearer to him than theirs. He took the deepest interest in all projects—social, intellectual, and athletic—which made for their welfare, and thoroughly earned the name of a "Students' Principal." During his term of office the University came under the influence of the Universities Act of 1889, and the operation of the Universities Commission; the McEwan Hall was built, and the University Union became a centre of social life among the students. Sir William Muir was an Oriental scholar of renown, and his writings on Mohammedan literature, on Mahomet, on the Caliphate, and allied topics earned for him the D.C.L.Oxon., the Ph.D. Bologna, and the LL.D. of Glasgow and Edinburgh.

THE forty-second annual conference of the British Pharmaceutical Society will take place at Brighton from July 24th to 28th, under the presidency of Mr. W. H. Gibson, F.C.S.

THE Committee of the Hospital for Sick Children, Great Ormond Street, has received a donation of 100 guineas from the Mercers' Company.

Correspondence.

THE REPORT OF THE IMPERIAL CANCER RESEARCH FUND.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I was interested to read the excellent article which appeared in your last issue, with the general tenour of which I am quite in accord. Nevertheless, it seems to me that a few points in reference to the scientific work conducted by the Fund calls for some comment.

Sir William Church, in moving the adoption of the annual report of the General Committee, is stated to have said that "the malignancy of cancer appears to consist in the inherent power the cells possess of division and multiplication. If we can find out the nature of this apparently unlimited growth it is not unreasonable to hope that we may be successful in obtaining means for checking or limiting their proliferation, and thus neutralising their malignancy."

I venture to submit that the conclusions regarding the nature of this unlimited growth and the probable means of checking or limiting the cell proliferation and neutralising the malignancy of the cells or their secretion have already been advanced in your columns and elsewhere.

Dr. J. Beard (1) has stated that it is not in the nature of parasitic maladies to lead to that unrestricted cellular increase and multiplication such as is characteristic of cancer. According to his investigations founded on embryological research, for some time he has taught, as for example, say, in the fowl, that the fertilised egg or the product of the union of sperm and egg does not *directly* give rise to the chick, but to a pre-embryonic "trophoblast" or larva; in man the chorion, which is capable of indefinite unrestricted cellular increase and multiplication. Upon this trophoblast arise the "primary germ cells," one of which forms the embryo. The rest migrate into the embryo, the majority reaching the germinal ridge from which the reproductive cells arise, and which thus are not formed by the embryo, but handed down to it in "morphological continuity," and for which it serves as a temporary shelter. It never happens, however, that all the germ cells find their way to the normal position in the embryo. Some may remain dormant, commencing later to grow. Cancer is this uncontrolled and imperfect attempt to repeat the life cycle of trophoblast and germ cells with all their enormous inherent potentialities of cell growth and other properties. Dr. Beard himself notes that Nusbaum in 1880 enunciated the conclusion that the germ cells must be special cells of the egg cleavage, which at no time took a share in forming the individual, but which were intended for future generations; that is to say, the segmented egg divides into somatic cells and the germ cells. This, or that of Boveri is the hypothesis apparently entertained in the Report of the Imperial Cancer Research Fund. On the other hand, Dr. Beard holds that when cleavage is really finished there are no somatic cells present, that the formation of germ cells is found to take place prior to the appearance of any trace of an embryo.

Amongst other confirmatory facts supporting Dr. Beard's conclusions by various observers may be noted the recent embryological conclusions of Dr. J. Voigt (Göttingen). He has found, as I understand, that human trophoblast possesses the structure of carcinoma even down to the "prickles" of squamous epithelioma, and he, like Dr. Beard, also comments on the fact that trophoblast of *early* gestation and carcinoma have the like physiological properties.

The one hopeful aspect of this embryological view, as taught by Dr. Beard, is that in normal development at a certain period the embryo is able to suppress the trophoblastic foundation upon which it arises; in the commencing functional activities of the pancreas which initiates an alkaline digestion and ferment—"with good reason for the hope if not the sure belief

that the same means might also be potent when directed against and in the treatment of cancer."

On other grounds, as pointed out I(2) had myself independently arrived at the conclusion that in cancer the function of the pancreas was in part at fault, and had been led to commence trial of hypodermic injections of its proteolytic ferment trypsin, in the treatment of inoperable cancer.

Subsequently, and in the now admitted failure of "sera," Dr. Beard (3) drew attention to the important fact discovered by Prof. Blumenthal, Bergell and others (Berlin), that all carcinomata are always very easily digested by pancreatin.

So that the import of trypsin and its indication in the treatment of cancer alone, or aided by other substances which increase its action, has been arrived at independently by different observers and from different routes of enquiry.

Hitherto I may remark that no adequate explanation has been advanced of cases in which cancer has been known to disappear spontaneously. In view of the above considerations, it is not unreasonable to suggest that the function of the pancreas, temporarily interfered with or inhibited, has been restored. So also in the question of age incidence, the possible premature decay of the pancreas in advancing years may be suggested, or in cases of cancer in the young, its imperfect developmental function. Just as the amylolytic properties of saliva are known to vary in different animals so also possibly may the proteolytic properties of the pancreatic ferment—explanatory of varying susceptibility to transplanted growth, or that this secretion sufficient to deal with the natural need of the economy is not sufficient to control the transplanted growth, or neutralise the intracellular acid malignancy.

I am, Sir, yours truly,

JOHN A. SHAW-MACKENZIE, M.D.Lond.

ABOLITION OF VIVISECTION.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR.—That distinguished member of our profession, Dr. Hadwen, who devotes his talents so generously to the cause of anti-vivisection, seems to have quite won over the *Evening Standard*. Supporting Dr. Hadwen's views, the Editor in his issue of July 15th appears to insist upon what he styles "the guiding principle that dumb animals should not be made to suffer that the higher may gain a problematical benefit." One wonders whether the Editor has ever heard of the practice of castrating and splaying animals with the object of making them more docile, or rendering their flesh more suitable for food. Is he aware that these painful operations are performed without anæsthesia upon at least one half of all the horses, cattle, sheep, swine, and fowls, used in the service of man? Will he tell us whether the infliction of such an amount of pain with such an aim is justifiable on the grounds of expediency or morality; and if not whether he does not consider he might well begin with an endeavour to diminish this vast amount of suffering before attempting to put an end to experimentation on animals, which, even at the grotesquely

exaggerated estimate of fanatics, cannot be considered as more than a single pin-prick in comparison.

I am, Sir, yours truly,

PHYSIOLOGIST.

"ALLUROPHOBIA," OR FEAR OF CATS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR.—In your interesting article on the above subject various symptoms are enumerated as having been produced by the presence of cats—sneezing, chilly sensations, suggestive of "catarrh." We are surprised there is no mention of "catalepsy," nor is any allusion made to female patients being more susceptible during the "catamenia"!

Of course, numerous other symptoms could be collected and form a category. Should the complaints produced by allurophobia become at any time epidemic, it would be nothing less than a "catastrophe," for the treatment of which a mere cataplasm would not be sufficient. In well-marked hysterical cases the threatened application of the cat (and nine tails) might prove effective. We only wish that "allurophobia" (or fear of the cat) could be extended to the East End hooligan.

I am, sir, yours truly,

London, W., July 14th. ALEXANDER DUKE.

THE GUILD OF HEALTH.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR.—In your "Notices to Correspondents" you offer the following remark:—"Mr. C. H. S.—The insertion of your letter would open up a discussion on religious subjects, for which our columns are unsuitable, and which it has always been our rule to avoid."

Now, Sir, I submit that credential religion is as closely allied with insanity as is alcohol, and since the discussion of one in a medical journal is as necessary as that of the other, that is if we hope to penetrate into the causes and deplete our public asylums of so many sad cases of so-called religious mania.

In a clerical contemporary a work by Mr. A. Lewis Bettany, "The Confessions of Lord Byron," is reviewed, and among them is one where the poet regards insanity as having been mistaken for inspiration—an opinion beyond doubt that numbers share in.

I am, Sir, yours truly,

CLEMENT H. SERS.

Brighton, July 10th, 1905.

[To discuss religious beliefs is an entirely different matter from the scientific consideration of melancholia, of which religious tendencies are a marked symptom.—ED].

Obituary.

SIR WILLIAM MUIR, K.C.S.I.

EDINBURGH has lost one of its representative men in the person of Sir William Muir, who was, from 1885 to 1903, Principal of the University of Edinburgh, and a member of the Civil Service of India from 1837 to 1876, but he will probably be remembered most for the great services rendered to the University of Edinburgh during the eventful year when changes in the constitution of the Scottish colleges made by the Act (1889) led to a modification of the curriculum adopted by the Universities Commission. Sir William Muir showed a great and sympathetic interest in schemes for the welfare of the students. He received the honorary degrees of D.C.L. of the University of Oxford, LL.D. of the Universities of Cambridge, Edinburgh, and Glasgow, and Ph.D. of the University of Bologna. He died at the advanced age of eighty-six. See also notice from our own correspondent in Scotland.

JOHN GORMLEY, B.A., R.U.I., L.R.C.P. and S.Ed., OF LIVERPOOL.

ON the 13th inst. the interment took place of Dr. John Gormley, one of the oldest and most respected medical men at the north end of the city. Taking his degree of B.A. at the Royal University of Ireland,

he left Castlereagh, his native place, to join the medical profession, and for upwards of thirty years in Liverpool the best traditions of that profession were sustained by him.

Literature.

THE DENTAL ANNUAL FOR 1905. (a)

THE cost of bringing out the Dental Annual must be very considerable; and if the work had not proved a great success it could hardly have survived a second year. That the third edition is more valuable than its predecessors is evident, and its greater success seems assured. This year the important question of anæsthesia is fully discussed, and a greater number of notes than in previous editions are given on materia medica and other subjects. All the leading men, a long list, who contributed monographs to the first issue have revised and brought their contributions up-to-date, and a great number of authorities who have not before written for the Annual now send valuable papers or notes on a great variety of scientific and practical subjects. The Annual is now an established institution, and needs no pressing upon the attention of dental practitioners and workers in dental science; it is moreover a directory to the profession so that it supplies useful information in a dual capacity.

MEALS MEDICINAL. (b)

WE have not been able to make up our minds after reading "Meals Medicinal," whether its author, Dr. Fernie, wishes us to take him seriously, or whether his treatise is an elaborate practical joke. This contribution to the science of medicine is dedicated to "Our 'Little Marys'" (playfully named); "with the Homage of a Lifetime spent in their Service"—an inscription which shows that Dr. Fernie is abreast with the humour of the day, even if his scientific acquirements are not those to which the term "orthodox" could be unreservedly applied. Of meals we learn little; of articles of diet much. The book deals, in a delightfully discursive, irresponsible way, with most of the foods, drinks, and drugs that enter the stomach of man. Dr. Fernie is so full of information of all sorts that he can never stick to one subject at a time, but roams off when discussing water to formulate theories as to the value of light-treatment, to the stories of Ruskin's disgust with his doctors, whilst he leaves us in the middle of tea to discourse upon a child's ideas of the diet of the Almighty. Of quotations the book is a mine; we catch, in turning over the leaves, citations from the following (*inter alia*):—Oliver Wendell Holmes, Virgil, Mark Twain, Robert Hutchinson, Sydney Smith, Keats, Dagonet, Pliny, Boswell, Charles Lamb, Dryden, Jane Austen, Chaucer, Lewis Carroll, Horace, Alexander Haig, Emerson, Hartly Coleridge, Pepys, Dr. Martineau, Horace Walpole, Stevenson, Ruskin, Dickens, Austen Dobson, and (need we add?) Shakespeare, and the Bible. Most of these are the reverse of *à propos*. On the other hand, there is a quantity of curious lore about the healing properties of foods and herbs, which has an interest of its own, but most of it is retailed with an air of verisimilitude that makes it difficult to judge whether or not the author adopts the ascribed virtues as his own opinions. On the whole, we are inclined to think that Dr. Fernie has no theoretical axe to grind, but is merely an irrepressible *raconteur* who must out with anything he reads or hears. And he reads and hears a good deal. It seems almost ungrateful to point out that his ideas of the value for diabetics of ordinary cream and Devonshire are the reverse of those of other authorities, or that Niels Finsen was not born in 1832, when he is stated (p. 725) to have made his famous discovery of the curative value of red light in small-pox—probably

the least trustworthy of any of Finsen's observations. For anyone who wishes to throw aside the cares of practice for an hour after dinner and wander into virgin forests of odd ideas and good yarns, we can heartily recommend these amusing digressive pages.

LAKE ON DISEASES OF THE EAR. (a)

THIS work, now in its second edition, is primarily intended for the instruction of those who propose to make a special study of diseases of the organ of hearing, and the author goes very thoroughly into the details of the various manipulations and operations which for the most part are far beyond the scope of any but a specialist. Nevertheless, the general practitioner will find therein the information that will enable him to diagnose such conditions as are amenable to direct observation, and he will derive material assistance from the numerous illustrations, especially from the three sheets of coloured plates that give a vivid idea of the lesions they depict.

Aural surgery has the reputation of being an ungrateful department of practice, but it is evident that the specialist can in suitable cases do a great deal to improve hearing, and to check the spread of aural disease to dangerous because contiguous zones. This volume, which is of moderate dimensions, and price, is a succinct guide to the pathology and treatment of ear diseases, and will be equally welcome to the general practitioner and to those who aspire to a more particular knowledge of the subject.

Literary Notes and Gossip.

THE Association for the Oral Instruction of the Deaf and Dumb, in their recently-issued report for the past year, indicate much success in their efforts to secure adequate training for teachers and instruction for children.

THE Livingstone College Year-Book for 1905 is not only an exceptionally interesting record of the work of this admirable missionary college, but it also contains hints and suggestions on health, outfit, and travel which should prove of the greatest service to all travellers.

A VOLUME of essays by Professor Osler will be published early in the autumn. It is entitled "The Fixed Period," and is said to deal fully with the question of the proper life-period in men of affairs.

THE current issue of *Climate*, the useful quarterly journal of health and travel, edited by Dr. C. F. Harford, contains a paper by Colonel T. H. Hendley, I.M.S., on "Health of Europeans in India," and an article on "Tala-azar," by Dr. Sambon.

Medical News.

Royal College of Surgeons in England.

A QUARTERLY meeting of the Council was held at the College on Thursday, the 13th inst., Mr. John Tweedy, president, in the chair. The result of the election of members of council by the Fellows of the College was reported, and Mr. Edward Owen, Mr. Rickman J. Godlee, Mr. C. H. Golding-Bird, and Mr. Harrison Cripps took their seats on the council. Mr. John Tweedy was re-elected president, and Mr. Henry T. Butlin and Mr. Edmund Owen were elected vice-presidents for the ensuing year. The following professors and lecturers were elected:—Hunterian Professors, Warrington Haward, A. H. Cheate, H. J. Paterson, and C. G. Seligmann. Arris and Gale Lecturers, J. H. Watson and Sydney W. Curl. Erasmus Wilson Lecturer, James Sherren.

A Diploma of Membership was issued to Norman

(a) "The Dental Annual and Directory; a Year-book of Dental Surgery, with a Directory of the Dental Profession." London: Baillière, Tindall and Cox, 1905. Price 7s. 6d.

(b) "Meals Medicinal, with 'Herbal Simples' (of Edible Parts)". By W. T. Fernie, M.D. Bristol: J. Wright and Co. 1905. 9s.

(a) "Handbook of Diseases of the Ear." By Richard Lake, F.R.C.S., Surgeon to the Royal Ear Hospital. Second Edition, with plates. London: Baillière, Tindall and Cox, 1904. Price 6s.

Duncan Buchanan, of Canada, and a Diploma for the Licence in Dental Surgery to Francis Sydney Doran, of Manchester. It was determined to close the Museum during August and September for repairs and redecoration.

A report was received from the Committee of Management of the Conjoint Examining Board in reference to the application of the Cairo Medical School for recognition as a place of study for candidates for the diplomas of the two Royal Colleges. The committee recommended that, subject to certain conditions, candidates who have received the diploma in medicine and surgery of the Egyptian Government, after passing the required examinations and completing the curriculum of professional study at Cairo extending over four years, be admitted to the final examination of the Conjoint Board on the completion of one year of additional study at a recognised medical school and hospital in the United Kingdom, during which they shall complete the courses required by the regulations of the Conjoint Board. The conditions provide, among other things, that an official representative of the Examining Board of the Royal Colleges be appointed annually to attend, as visitor, the examinations of the Cairo Medical School and Hospital, which are held in December and January, to take a general survey of the examinations, and to note the methods of the examiners and the standard required in each subject. The committee also reported that a communication had been received from his Excellency the Minister of Education of the Egyptian Government expressing his complete concurrence in the conditions laid down. This report was approved and adopted by the Council, having previously received the approval of the Royal College of Physicians.

It was agreed to send an address of congratulation to the Royal College of Surgeons of Edinburgh on the occasion of its fourth Centenary Celebration.

Society of Chemical Industry.

THIS important Society, the membership of which now numbers between 4,000 and 5,000, held its annual meeting in London last week, a large number of scientific and manufacturing chemists having come over from the United States to support the president.—This year an American—Dr. H. W. Nichols, of New York.

The business part of the Congress was held in University College, in which the election of council took place, and the president delivered an address, founded on personal knowledge and experience of the management of chemical industrial organisation and research. A cordial vote having been accorded to Dr. Nichols for his address, Dr. Edward Divers, F.R.S., was inducted as president-elect.

The entire week was filled in with sessional work, receptions by the Lord Mayor and various scientific societies, banquets, excursions to Windsor, Woolwich Arsenal, Greenwich Hospital, the Royal Botanical Gardens, and was wound up by a visit on Saturday to the extensive manufacturing premises and chemical laboratories of Messrs. Burroughs Wellcome and Co., at Dartford. By a coincidence, the year 1905 happens to fall on the quarter-century of foundation both of the Society of Chemical Industry and that of Messrs. Burroughs Wellcome and Co. In a medical journal but scant reference is necessary to the firm in question, for what medical man in the civilised world does not know of its productions in the daily practice of his profession? At Dartford could be seen the laboratories whence the tabloids, the malt extract, the medical equipments for travellers, &c., emanate, but the day was a holiday, and the factory hands, as well as the Society of Chemical Industry were being entertained in commemoration of the dual event by the principal, Mr. H. E. Wellcome, with a sumptuous luncheon, to which more than fifteen hundred sat down, no fewer than thirteen hundred being employees on this gigantic establishment. After various speeches and toasts had been made and responded to by eminent members of the medical and scientific professions, the natural

trend of which was towards the blending of scientific medicine with progressive pharmacy, an enthusiastic recognition was accorded to Mr. Wellcome for the munificence of his reception of the Society, and by the enormous staff of workers in testimony of the popularity and esteem in which he is held by them. The rest of the day was spent by the visitors in witnessing the sports and entertainments provided. In the evening a *recherche* dinner was partaken of by nearly two hundred specially-invited guests, among whom were many medical men and their ladies. The extensive grounds of the Wellcome Club and Institute were subsequently illuminated, and a display of fireworks closed a most enjoyable day's outing, the visitors being taken back to London by a specially provided train.

The Coombe Hospital, Dublin.

THE annual meeting of the Coombe Hospital was held on the 6th inst., the Lord Mayor in the chair. The Report stated that a total of 17,351 patients had been treated in one or other of the departments of the Hospital, and that only five deaths had occurred. The maternity department had been much improved, a suitable waiting ward and a labour theatre having been added. The number of students attending the hospital had passed all previous figures, and many past students had returned for second or third periods of work. The number of probationary nurses also remained satisfactory. Among those who took part in the meeting were the Master (Dr. Stevens), Sir John Moore, Rev. Dr. Hughes, and Dr. Neill.

Annual Meeting of the British Medical Association.

THE Seventy-third Annual Meeting of the British Medical Association will be held at Leicester on July 24th, 25th, 26th, 27th and 28th, under the presidency of George Cooper Franklin, F.R.C.S. The first general meeting of members will be held on Monday, July 24th, at 2 o'clock p.m., to be followed by the representative meeting. On Tuesday, July 25th, the representatives will resume their session at 10 o'clock, and at 2 o'clock there will be the adjourned general meeting. At 8.30 o'clock in the evening the President will deliver his Presidential Address and receive the colonial and foreign guests in the Temperance Hall, and present the Gold Medal of Merit of the Association to Sir Constantine Holman, M.D., and to Mr. Andrew Clark, D.Sc., F.R.C.S., and the Stewart Prize to Mr. Wm. Henry Power, C.B., F.R.S., F.R.C.S. On Wednesday an Address in Medicine will be delivered by Henry Maudsley, LL.D., M.D., F.R.C.P., after which the adjourned general meeting will be held to consider where the Association shall meet in 1906 and to nominate the President-elect, followed by the representative meeting. On Thursday, at 2 p.m., an Address in Surgery will be delivered by Charles John Bond, F.R.C.S.; at 3.30 p.m. the representative meeting will continue its work. At 7.30 p.m. the annual dinner of the Association will be held in the County Assembly Rooms. On Friday, at 8 p.m., a popular lecture will be delivered by Professor William Stirling, D.Sc., M.D., F.R.S.E., on "Rest and Fatigue." On Wednesday, Thursday, and Friday, from 10 a.m. to 1 p.m., the following twelve scientific sections: Medicine, Surgery, State Medicine, Industrial Hygiene and Diseases of Occupation, Laryngology, Otolaryngology, and Rhinology; Navy, Army and Ambulance; Obstetrics and Gynaecology, Ophthalmology, Psychological Medicine, Pathology, Dental Surgery, Tropical Diseases will meet in the Technical Schools, the work promising to be of special interest. Much hospitality will be offered to members. On Wednesday afternoon, July 26th, the chairman of the Leicester Infirmary will give a garden party in the grounds of the Infirmary, and in the evening the President and members of the Midland Branch of the Association will give an entertainment at the Museum buildings. On Thursday afternoon there will be a garden party given by the President and members of the Leicester Medical Society in the grounds of the County Asylum and another given by Mr. Maurice Levy, M.P., at Hamberstone Hall. On the evening of this day the annual

dinner will take place, and the Ladies' Committee has arranged an entertainment at the Grand Hotel. On Friday afternoon Mr. Samuel Faire, J.P., will give a garden party at Glenfield Frith, and there will be an excursion to Belvoir Castle, the seat of the Duke of Rutland, and also a golf match on the Leicestershire Golf Club links. In the evening the Mayor of Leicester will give a garden fête in Abbey Park. On Saturday various excursions have been arranged to Buxton and neighbourhood, and the Charnwood Forest district. On July 27th, 28th, and 29th, the cricket match between Leicestershire and Derbyshire will be in progress on the County Grounds, Leicester. The Entertainments Committee has arranged that various public works and factories shall be open for inspection to members of the Association and their friends.

The Royal Hospital for Incurables, Dublin.

THE Royal Hospital for Incurables, in existence for more than one hundred and sixty years, made a new move this year in summoning the first annual meeting of its friends and subscribers. The meeting, which was held at the Hospital on the 6th inst., was well attended. The report showed that of the 213 beds in the hospital, the average number occupied through the year had been 205. Of these thirty-nine were reserved for consumptive patients, and thirty-two for cancer. The result of the treatment of consumption in the hospital showed that even among the cases classed as incurable, healthy surroundings, careful nursing, and sufficient feeding were able to cause a great improvement in health and a prolongation of life. The ordinary expenditure for the year amounted to £7,137 13s. 5d., while the ordinary income was £6,392 4s. 8d., leaving a deficit of £745 8s. 9d. to be met out of capital. During the year Dr. J. M. Finny had become consulting physician to the hospital in room of the late Dr. Cranny. Among those who spoke at the meeting were Mr. William Fry, Junr. (chairman), the Lord Mayor of Dublin, Sir George Roche, and Mr. Maurice Dockrell.

Trinity College, Dublin.

LIST of successful candidates during Trinity Term, 1905. "Previous" Medical Examination.

Anatomy and Institutes of Medicine.—William S. Thacker, Johannes C. Pretorius, Wilfred J. Dunn, and Frederick Stevenson, eq., David J. Miller and Allan J. Powell, eq., Charles H. O'Rorke and Edmond H. Sheehan, eq., James C. C. Hogan, Henry de C. Dillon and Thomas P. Dowley, eq., Denis J. Stokes, John A. L. Hahn, Albert V. J. Richardson, James R. Yourell, William Knapp, and James D. K. Roche, eq., Ernest N. Ryan and William H. Sutcliffe.

Physics and Chemistry.—Thomas A. Hughes, Arnold K. Henry, Albert Stals, John D. Kernan and Perceval G. Leeman, eq., William S. S. Boxwell, Charles G. S. Baronsfeather, Peter H. Lemass, James Alston, Louis Trichard and William R. Watson, eq., Charles H. Denham, Hubert G. Holdbrook and Robert E. T. Tatlow, eq., Adams A. McConnell, John C. Baker and Ernest Jameson, eq., Frank Smartt and Alexander S. M. Winder, eq., Gervase Scroope, Alfred H. Smith.

Botany and Zoology.—Arnold K. Henry, David L. McCullough, Beatrice M. Hamilton, Thomas A. Hughes and Cecil P. Smyly, eq., Perceval G. Leeman and William P. H. Smiley, eq., George Eliot, James H. Crane and William R. Watson, eq., Edward P. Allman-Smith and Hilgard Müller, eq., Adams A. McConnell, Marius A. Diemont, John Gardiner, and Henry H. Ormsby, eq., Euphon M. Maxwell and Eric J. Powell, eq., John D. Kernan, Victor G. Best and William A. Taylor, eq.

John Mallet Purser Medal.—Johannes C. Pretorius. The following were successful at the Medical Scholarship examination (Trinity Term, 1905):—

Anatomy and Institutes of Medicine.—William Pearson, Trin. Coll. Scholarship; Robert E. Wright, Stewart Scholarship.

Physics, Chemistry, Botany and Zoology.—Richard P. Hadden, Trin. Coll. Scholarship; Hugh R. M. Ferguson (Sch.), Stewart Scholarship.

University of Glasgow.

THE following have satisfied the Examiners in the fourth (final) professional examination for M.B., Ch.B.:—

Andrew Blair Aitken, George A. Allan, William S. Allan, Andrew Allison, Andrew W. Anderson, John Bain, M.A.; Annie A. Baird, M.A., James H. Baird, B.A., Hugh Barr, Andrew F. Bell, Ethel L. Chapman, Jeannie T. Clark, Robert W. Dale, M.A., David W. Davidson, Robert S. Dewar, M.A., Hugh M.M. Donaldson, Allan C. Douglas, John S. Dunn, M.A., Eric J. Dyke, Hamilton W. Dyke, Alexander B. Ferguson, Mary T. Gallagher, William Gilchrist, William H. Gillatt, William M. Gilmour, Joseph Glaister, Louis L. Greig, William Grier, Alexander R. F. Hay, James W. Hay, Ralph V. Howell, John M. Huey, James Hunter, Harry S. Hutchison, B.Sc., Arthur Innes, William B. Jack, Arnold E. Jones, Robert D. Kennedy, William L. Kirkwood, Alexander L. George Hugh Logan, William Logie, John B. McCabe, Walter G. Macdonald, M.A., Duncan M'Ewan, Hugh A. Macewen, Robert M. Macfarlane, James D. Macfie, Milne M'Intyre, John M'Millan, Peter Maguire, William B. M. Martin, Robert May, Henry J. Milligan, Macdonald Munro, Frank A. Murray, John D. Nisbet, David Panman, Henry S. Ranken, Cunison D. Rankin, Thomas T. Rankin, John Reid, James M. Renton, William Rolland, Alexander C. Russell, Frank D. Scott, Jane R. Shaw, Lily Smellie, James A. Somerville, Arthur A. Stewart, Daniel Stewart, John L. Stewart, M.A., William A. Stuart, Joseph R. Sutherland, Elizabeth T. Talbert, John Taylor, William L. Walker, M.A., Robert Wallace, Alexander McM. Watson, Archibald C. West, Archibald S. Wilson.

The following passed with distinction in the subjects indicated:—

In (a) Surgery and Clinical Surgery, (b) Practice of Medicine and Clinical Medicine—Jeannie T. Clark, Peter Macquire. In (a) Surgery and Clinical Surgery; (b) Midwifery—James H. Baird, B.A. In Surgery and Clinical Surgery—Hugh A. Macewen. In Medicine and Clinical Medicine—George A. Allan, Andrew Allison, John S. Dunn, M.A., Arthur Innes, William B. Jack, Cunison D. Rankin, John L. Stewart, M.A. John Taylor.

Royal College of Surgeons in Ireland.

FELLOWSHIP EXAMINATIONS.

MR. MICHAEL ULICK O'SULLIVAN, L.R.C.S., Edin., &c., having passed the necessary examination, has been admitted a Fellow of the College.

Royal College of Physicians and Surgeons (Ireland).

THE following candidates have passed the second Professional Examination as undernoted:—*With Honours*—T. C. Boyd, J. C. L. Day, J. Murray, T. J. M'Donnell, W. G. Ridgway. *Arranged in Alphabetical Order*—P. H. Black, T. P. Cormack, P. J. Cusack, J. J. Cuskelly, G. A. Finegan, J. P. Grainger, F. N. Holden, S. W. Hudson, C. Hyland, P. MacCarthy, M. J. Saunders, A. Sheridan, P. J. Timoney.

ST. MARY'S HOSPITAL, London, has received a bequest of £2,000 from the executors of Mr. J. H. Lucking towards the £17,000 additional income required to maintain the work of the hospital during the present year.

THE Secretary of State for India has received the following telegrams, dated July 8th, in regard to the plague:—"Deaths from plague reported in places outside Bombay Presidency in June last: Madras Presidency, 41; Calcutta, 160; Bengal (excluding Calcutta), 936; United Provinces of Agra and Oude, 2,258; Punjab, 21,601; Burma, 416; Central Provinces, 6; Mysore State, 124; Hyderabad State, 11; Rajputana, 556; Kashmir, 95. No plague reported elsewhere.

ON Wednesday last, her Royal Highness the Duchess of Argyll opened the buildings for epileptic children at the Colony of Mercy, Lingfield, Surrey. These homes are intended to receive poor epileptic boys and girls whose maintenance is assured by Boards of Guardians and other private bodies.

Notices to Correspondents, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

COUNTRY DOCTOR.—Your story is not incredible. Ignorance on these points among the poor is astonishing. A labourer near Brighton is reported to have become indignant at the comments of a doctor on a tuberculous pig, and to have said that an animal like that was tastier. "We never kill a pig of his sort till he coughs, then we know the flesh is soft."

DR. F.—Quacks often advance as proof of their "electric" power the exhaustion that follows in themselves after massaging, whereas the most efficient worker is he who uses no more strength than is needed and is not exhausted by any amount of work which an ordinary man could get through. The personal requirement is physical strength, trained to do the will of a trained mind.

ALIENIST.—The X-Rays in epilepsy were first tried three years ago, upon the theory that epilepsy depends upon the instability of the, cellular brain elements, and the X-Rays stimulate protoplasm into greater activity. On the other hand, serious mental disturbance has been attributed to the action of the Rays. Manders claims that one in every thousand in Europe is epileptic.

DR. S. H. (Hull).—Roentgen's experimental works are published in *Annalen der Physik und Chemie*. He was born at Lennep in 1845, and graduated at Zurich.

L.S.A.—There were over 130 applicants for medical posts in connection with the London County Council, and twenty applicants were selected.

BABY-BOY TABLOIDS.

In his speech at Dartford on Saturday last, at the luncheon given in honour of the president and members of the Society of Chemical Industry, Mr. Hy. S. Wellcome said that among the many requests for Tabloids received from various parts of the world came a not uncommon one for "Baby-boy Tabloids," if, as was sometimes added, it was not an illegal act to use them.

MAB.—Your question does not appeal to the medical profession, therefore we cannot insert it in our columns. Try one of the lay journals.

KERATITIS.—As far as we can judge from your statement your conduct was professionally correct.

JUDGE.—We have not heard any thing relating to your complaint.

M.D. EDIN. The Society is progressing very favourably.

PATH.—The subject will no doubt be brought forward at the ensuing meeting of the British Medical Association.

A COUNTRY MEMBER.—The last meeting of the session was held on the 13th inst., we hope to publish the report in our next.

A. S. WESTON.—The report referred to is of American origin, we cannot vouch for the truth of the statements therein made; to us they appear not only incredible, but practically impossible.

A SCOTCHMAN.—The fees are somewhat less at some of the Scotch Colleges, than they are either at the English or Irish Colleges.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JULY 19th.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (11 Chandos Street, Cavendish Square, W.)—5.30 p.m. Annual General Meeting. Election of Office Bearers and Report of the Council.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chentles Street, W.C.)—4 p.m. Mr. J. Paydoe: Clinique. (Surgical.) 5.15 p.m. Mr. A. Lane: Abdominal Surgery.

THURSDAY, JULY 20th.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (7 Fitzroy Square, W.)—5 p.m. Lecture:—Dr. H. Schnarlieb: Some Post-anæsthetic Complications. (Post-Graduate Course).

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chentles

Street, W.C.)—4 p.m. Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m. Mr. W. E. Miles: Neoplasms of the Rectum and Anus.

Vacancies.

- The Victoria University of Manchester. Junior Demonstrator in Physiology. Salary £100 per annum. Applications to the Registrar.
- The Hospital for Consumption and Diseases of the Chest, Brompton. Resident Medical Officer. Salary £200 per annum, with board and residence. Applications to the Secretary, at the Hospital. Frederick Wood, Secretary, Brompton.
- Borough of Leicester—Education Committee. Medical Officer. Salary £400 per annum. Applications to T. Groves, Secretary, Leicester.
- The Grocers' Company's Scholarships.—Salary £300 per annum. Applications to the Clerk of the Grocers' Company, Grocers' Hall, London, E.C.
- Parish of Hammersmith.—Infirmary Medical Superintendent and Workhouse Medical Officer required. Salary £250 per annum, with unfurnished house, coals, light, and washing. Applications to J. Lamb, Clerk to the Guardians, Guardians' Offices, 206 Goldhawk Road, Shepherd's Bush, W.
- Royal Berkshire Hospital, Reading.—Secretary and House Governor. Salary £200 per annum, with residence. Applications to the Secretary.
- The Royal National Hospital for Consumption, Ventnor.—Senior Resident Medical Officer. Salary £200 per annum, with board and lodging in the Hospital. Applications to the Secretary, 34 Craven Street, Charing Cross, London.
- Dorset County Hospital, Dorchester. House Surgeon. Salary £100 per annum. Applications to W. E. Groves, Valetta, Iceway Dorchester.
- Wallasey Dispensary and Victoria Central Hospital, Liscard.—House Surgeon. Salary £100 per annum, with good apartments, board, and service.—Applications to Mr. E. Russell Taylor, Kingscourt, Liscard, Cheshire.
- Weston-super-Mare.—House Surgeon. Salary £100 per annum, with board and residence in the Hospital. Applications to the Honorary Secretary.
- Royal City of Dublin, Hospital.—Pathologist, Anæsthetist, X Rayist and Dentist. Immediate applications to the Hon. Secretary, Medical Board.

Appointments.

- BALL, JOHN BRAMLEY, L.D.S.R.C.S.Eng.**, Dental House Surgeon to Guy's Hospital.
- BURNET, R. W. M.D.Aberd., F.R.C.P.Lond.**, Consulting Physician to the Great Northern Central Hospital.
- FORTY, ARTHUR ALAN, L.D.S.R.C.S.Eng.**, Dental House Surgeon to Guy's Hospital.
- HEWKLEY, FRANK, M.B.Durh., F.R.C.S.Eng.**, Honorary Physician to the St. Pancras and Northern Dispensary.
- SYMES-THOMPSON, H. E., M.D., M.R.C.P.Lond.**, Physician with charge of out-patients to the Great Northern Central Hospital.
- TEENFIELD, GEORGE HENRY, L.R.C.P.Lond., M.R.C.S.**, Surgeon to the Midland Railway at Bristol.
- WATERHOUSE, RUPERT, M.D.Lond., M.R.C.S.Eng.**, Pathologist and Curator of the Museum at the Royal United Hospital, Bath.

Births.

- BOURNE.**—On July 15th, at Bridge House, Halling, Rochester, the wife of H. J. F. Bourne, L.R.C.P., of a daughter.
- MISKIN.**—On July 12th, at Blade House, Kennington Road, London, the wife of Ernest Miskin, M.B.Lond., of a daughter.

Marriages.

- GIBSON-FLOWER.**—On July 15th, at St. John's Chapel, Melbourn. Frederick Gouborn Gibson, M.D., of Christchurch, New Zealand, to Dorothy Mary Flower, only daughter of James Flower, of Basingdon, Bexley, Kent.
- KLUMPP-CRAWFORD.**—On July 12th, at St. James' Church, Kidbrook. Ernest George Klumpp, M.B., of Wootton Bassett, Wilts., to Dora Elizabeth, daughter of Colonel Crawford, Royal Artillery (retired), of 13 Kidbrook Park Road, Blackheath.
- TRINDER-CROOKES.**—On July 1st, at Bembridge, I.W., Alfred Probus Trinder, M.R.C.S., L.R.C.P., to Constance Rose Nellie Crookes (née Masenll).
- WITT-WATTS.**—On July 15th, at St. George's, Hanover Square, Tansley. third son of the late Charles Witt, M.D., to Gertrude, widow of Colonel John Germain Watts, India (Bombay) Staff Corps, and only daughter of John Macdowell Hay.

Deaths.

- GABE.** On July 16th, at Westwood, Ashby de la Zouche, Leicestershire, Grace Winifred, the dearly beloved wife of John Rees Gabe, M.D., M.R.C.S.Eng., of 16 Macklenburgh Square, London.
- KAY.** On July 17th, at Bentley Cottage, Bentley, Hants. Mary, Ellen (Lille), the beloved wife of William Kay, M.R.C.S., L.S.A.

THE OPERATIVE TREATMENT OF RECTAL CANCER.

POST GRADUATE LECTURE. (a)

By EDWARD H. TAYLOR, M.D., UNIV. DUB., F.R.C.S.I.

Deputy Professor of Surgery, Trinity College, Dublin; Surgeon to Sir Patrick Dun's Hospital.

GENTLEMEN,—As I have had to deal with a considerable number of cases of cancer of the rectum in the course of the past eighteen months, I thought the present occasion would be very suitable for demonstrating to you the results which can be obtained by operation under favourable conditions, and explaining the particular form of operative procedure which I now employ. I must preface my remarks, however, with a very brief allusion to certain facts concerning the anatomy of the rectum. Nowadays, we assign as the limits of this segment of the bowel the level of the lower border of the third sacral vertebra above, the anal orifice below, and we further subdivide it into two parts, viz., an upper or intrapelvic part, the rectum proper, and a lower or extrapelvic part, the anal canal. Only for about half of its extent has the rectum any relationship to the peritoneum, and that of a limited character, viz., in front and on each side. From the level at which the membrane leaves it down to the commencement of the anal canal, the rectum is invested in both sexes by loose tissue containing a variable amount of fat together with the hæmorrhoidal blood vessels, nerves, lymphatics, &c., enclosed within what I may call its sheath of pelvic fascia, *i.e.*, the recto-vesical fascia in front separating it from the bladder, seminal vesicles, and prostate in the male, from the

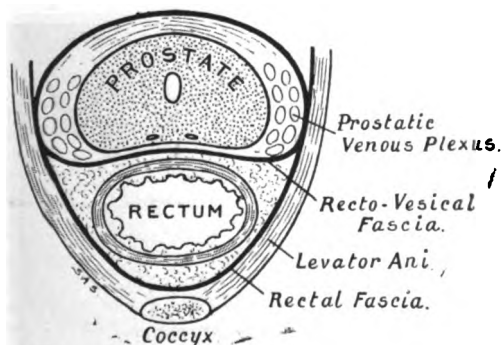

FIG. 1.—Diagrammatic representation of the pelvic fascia in its relationships to the rectum.

vagina in the female, and the rectal fascia behind, separating it from the sacrum and coccyx (Fig. 1). This fascial sheath possesses very great significance in connection with excision of the rectum. In approaching the bowel from behind after the coccyx and part of the sacrum have been removed, the rectal

layer just mentioned will be encountered and should be divided freely in the vertical direction before the rectum is sought for. I regard this apparently trivial detail one of no small importance as its omission would be very apt to lead to difficulty in the further stages of the operation. For instance, an operator oblivious of this fact, thinking he is in immediate contact with the rectum after the bone is removed, would probably expend his efforts for some time in merely detaching the pelvic fascia from the front of the sacrum upwards to a very undesirable extent. By opening the fascial sheath of the bowel promptly the perirectal fatty tissue is at once exposed, and the rectal wall identified.

With the limits which I have just assigned to the rectum, it is possible in nearly all cases by a digital examination to detect a malignant growth in its interior. Growths which are entirely out of the reach of the finger, especially if the examination be made with the aid of anæsthesia, must be regarded as being situated not in the rectum proper, but in the pelvic colon.

In the cases which I am about to demonstrate the disease was for the most part confined to the rectum. In some the pelvic colon was involved to a slight extent, but in none was the sphincteric zone encroached upon. In all the plan of operation which I carried out was the same, and as this differs in many respects from the methods usually described, I propose to devote the remainder of the lecture to the description of its details, and the results generally which I have obtained.

There are just two matters, however, to which I must refer before entering upon the operative details. The first of these is the selection of suitable cases for operation. Extension of the growth beyond the peripheral confines of the bowel, but more especially in front should be regarded as a distinct contra-indication. The best way for roughly determining the local extent of the disease is to introduce the examining finger through the stricture, if one exists, or to the upper border of the growth if this involves but a part of the circumference of the bowel, and by drawing the mass down towards the anus, observe how far the rectum retains its natural mobility. Immobility of the diseased segment and marked rigidity of the surrounding tissues indicate extensive local infiltration, and point strongly against excision being attempted. The normal range of mobility of the rectum in the vertical direction varies within fairly wide limits. In one patient a digital examination will reveal great laxity of the perirectal tissues, as evidenced by the facility with which the growth moves up and down with the finger engaged within the bowel. I always regard this as a most hopeful sign, as it enables one, among other things, to form a fairly correct estimate of the ease with which the pelvic colon will descend in the course of the operation. In another patient with possibly quite a limited amount of disease one may fail to get much evidence of mobility, and the probability is that in such a case considerable difficulty will be encountered in drawing down the pelvic colon to the level of the anus. I have noted

(a) Delivered in Sir Patrick Dun's Hospital, June 19th, 1905.

this difficulty in males more frequently than in females, and in stout persons more constantly than in those of spare build.

The second point to which I would direct your

FIG. 2.—Position of patient in the operation of trans-sacral excision of the rectum.

attention is the necessity for careful preparatory treatment. Very often patients suffering from rectal cancer experience progressively increasing difficulty in securing a free evacuation of the bowels. Now, above all things, this is a matter which must be attended to; indeed, its importance cannot be over-estimated. My practice is to devote some days towards attaining this end. Large doses of castor oil serve the purpose admirably. I find it well to administer about three doses altogether, at intervals of forty-eight hours, or the first dose of oil may be followed in forty-eight hours by two ounces of black draught, and later on by another dose of oil. During this period the patient's diet consists of fish, milk, thick soups, eggs beaten up, &c., and no food is permitted which would be calculated to leave much residue in the bowel. Unless a marked degree of stricture is present the bowel is washed out each evening with weak boracic solution. Twenty-four hours before the operation the patient is given opium in the form of *Pil. saponis*, grs. v., and the same dose is repeated at intervals of four hours until three or four pills have been taken. This ensures a quiescent state of the bowels both during and for some time after the operation, and as we shall see, this means a great deal in promoting a smooth and uneventful convalescence.

Let us now pause for a moment to consider wherein consist the principal points of difference between the rectum, and the other sub-divisions of the

large bowel, at least so far as the operation of resection is concerned. The principal are as follows:—The rectum is more fixed, with a partial investment of peritoneum; its blood vessels run vertically to its long axis instead of at right angles as is the case with the intestinal vessels higher up. The principal vessels are the superior hæmorrhoidal, the two main divisions of which descend upon the posterior and lateral aspects of the bowel. Upon the integrity of these vessels its vitality mainly depends, and consequently they must be treated with very great circumspection. Finally, the rectum at its termination is provided with a highly co-ordinated sphincteric apparatus, and it should be one of the great aims of the operation of excision to leave it intact and capable of carrying on its normal functions.

In anticipation of what is about to follow, I may mention that end-to-end junction of the healthy segments of the rectum after excision is not at all satisfactory. Not alone is it a difficult matter to bring the bowel edges neatly and accurately into apposition, but the suturing process is greatly hampered if attempted through the sacral wound, and even if one were to succeed in carrying it out the failure of union would be very apt to occur as the opposing surfaces devoid of peritoneum to a large extent, if not entirely, do not lend themselves to rapid union. Furthermore, even if an attempt at union were to take place, the resistance offered by the undivided sphincters would result in severe strain on the suture line, and very possibly rupture followed by fæcal extravasation into the pelvic cellular tissue. Apart from the immediate danger of sepsis with its possibly fatal consequences, such an accident would most likely entail the establishment of a fæcal fistula in the sacral region which would need to be closed later by a second operation.

THE OPERATION.—The patient having been anaesthetised by nitrous oxide gas and ether, I first wash out the rectum as thoroughly as possible. I employ boracic solution for this purpose, and take care to ensure that all the fluid injected comes back again. The lower part of the rectum and the seat of disease

FIG. 3.—This figure represents the extent of the superficial incision. The line of bone section appears as a double dotted line, and below the tip of the coccyx the levatores ani muscles, together with the ano-coccygeal raphe, are indicated in the depth of the wound.

are then wiped dry with some muslin swabs or pledgets of absorbent wool held in forceps. I always wear rubber gloves during this washing-out process, and change them for another sterilised pair before proceeding further with the operation.

The patient is now placed upon the left side with a small air cushion protected by a mackintosh beneath

to be accompanied by tearing of the rectal wall, and contamination of the wound with matter from within the bowel. I much prefer to obtain command of the latter above the disease, and subsequently to proceed with the excision. Further I have no doubt whatever that the best way for accomplishing this is to open into the cavity of the peritoneum (pararectal fossa)

without delay. This is most readily done by snipping through the perirectal fatty tissue between catch forceps just below the divided sacrum and about half an inch to the right of the bowel wall (Fig. 4). If the tissues are divided too close to the latter there would be considerable danger of wounding the corresponding main division of the superior hæmorrhoidal artery. The right index finger is now introduced into the pelvic cavity through the peritoneal aperture, and made to project on the opposite side of the bowel, where it can be cut down upon and pushed through. It is an easy matter then to pass a strip of gauze around the rectum to serve as a traction loop. A limited division of the fatty tissue behind the rectum and of the lateral peritoneal reflection on each side permits of a fairly extensive stretch of bowel being drawn up into the wound, indeed it is often surprising how readily the pelvic colon comes down when its mesentery is thus partially divided. Of course, a free division of this structure would be dangerous owing to the risk of wounding the hæmorrhoidal vessels. If any doubt now exists as

FIG. 4.—In this figure, the coccyx and lower part ($\frac{3}{4}$ in.) of the sacrum have been removed. The divided margins of the rectal pelvic fascia are held aside with forceps and the pelvic cavity has been opened into. Traction loops of silk separate the margins of the peritoneal aperture.

the great trochanter. The buttocks are brought on a line with the edge of the table, and the knees are well drawn up. The skin is disinfected as thoroughly as possible, and an incision about five inches in length is made exactly in the middle line from near the middle of the sacrum to within an inch of the anus. The wound is rapidly extended through the subcutaneous tissues until the coccyx and lower part of the sacrum are exposed. By moving the tip of the latter backwards and forwards one readily perceives the level of the sacro-coccygeal articulation provided it is not ankylosed. I now measure off a piece of the lower end of the sacrum about $\frac{3}{4}$ -inch in extent by

laying my middle finger across the bone immediately above the joint line and drawing a scalpel across the tendinous structures at this level (Figs. 2 and 3). The tissues attached to the bone below this are divided on each side, the osseous section is completed, an Adams' saw answering admirably for the purpose, and the coccyx and lower part of the sacrum are removed. In addition to some small branches of the sciatic artery which require the application of hæmostatic forceps, the middle sacral artery is divided and is sometimes a little difficult to secure owing to its very close connection with the front of the sacrum. The rectal layer of the parietal pelvic fascia is next identified, picked up and divided between catch forceps. It is advisable also to extend the incision downwards for a short distance into the ano-coccygeal raphé between the levatores ani (Fig. 3). The next step in the operation I regard as the real key to the situation, viz., the isolation of the diseased segment of the bowel. Some operators adopt the plan of first dividing the gut below the diseased part and then proceed to separate it from below upwards, but I do not think this

wise, because the division is almost certain

to the exact position of the upper limit of the growth an assistant introduces his finger into the rectum and indicates a point fully an inch above the diseased area. A stout silk ligature is applied here and tied as tightly as is possible. Another ligature is similarly applied still higher up, whereupon the bowel is cut across between the two, carefully wiped dry, and disinfected, as well as can be, with liquid carbolic acid or the cautery. Before proceeding with the dissection further a good plan is to fix the upper bowel segment temporarily to the skin of the buttock as shown in Fig. 5.

FIG. 5.—The bowel has been divided between silk sutures above the growth. The upper segment is fixed temporarily to the skin of the buttock, while the lower is being separated from its surroundings. The aneurysm needle threaded with catgut has been passed beneath the middle hæmorrhoidal artery. Note the line of peritoneal division represented in the figure below the eye of the needle.

does not usually present much difficulty. In front the peritoneum at the recto-vesical or recto-vaginal reflection, as the case may be, is divided, and then with the help of the index finger or a blunt dissector the bowel is separated from the bladder and prostate in the male, from the vagina in the female. On each side the so-called "lateral ligaments" of the rectum

through the anus it is advisable to suture its anterior or serous aspect to the divided peritoneum of the recto-vesical or recto-vaginal pouch (Fig. 5). The next step consists in connecting the everted mucous membrane of the lower part of the rectum to the side of the bowel which has been made to emerge at the anus, as is represented in Fig. 6. A useful precaution also at this stage is to connect the ligatured extremity of the gut to the skin in the vicinity of the anus by a temporary suture. The free ends of the occluding suture may be employed for this purpose. This prevents the parts slipping back and receding within the anal aperture.

It now remains to close the large wound in the sacral region. It is well to introduce a few deep sutures of catgut first through the musculature of the pelvic diaphragm, and the rectal wall. These sutures serve to take the strain off those already introduced at the anus, and prevent the bowel slipping back. Finally the greater part of the wound is closed with silkworm gut and a couple of strips of iodoform or xeroform gauze are introduced for drainage purposes as there is likely to be a considerable amount of sero-sanguineous oozing after the patient is put to bed (Fig. 7). The gauze is removed after forty-eight hours and a fresh plug introduced.

As it is desirable to keep the bowels constipated for some days after the operation, the administration of opium is continued. *Pil. plumbi c. opio* answers very well. The protruding extremity of the bowel is inspected from time to time to see if there is any evidence of gaseous or fecal accumulation above the ligature. As a rule there is no need to interfere with this for at least three days. If necessary, a small puncture may then be made and flatus allowed to escape. By this time the opposing peritoneal surfaces have acquired adhesions, the pelvic cavity is sealed up and the protruding bowel has become securely anchored in its new site. If after removal or spontaneous separation of the ligature the parts do not recede gradually within the grasp of the sphincter, they may be trimmed with scissors, bleeding points being ligatured with catgut, but this is seldom necessary. At the end of a week or ten days the bowels are made to act freely with castor oil.

FIG. 6.—The upper segment of the bowel occluded by a silk ligature has been drawn down through the anus and connected to the everted mucous membrane of the anal canal by a series of interrupted sutures. The deep sutures connecting the levatores ani muscles are shown in situ.

containing the middle hæmorrhoidal vessels are ligatured with catgut—I employ this material for all ligatures in this operation (Fig. 5). By snipping through the perirectal tissues on each side with blunt-pointed scissors the rectum is separated from its connections quite down to the commencement of the anal canal.

At this stage of the procedure two alternatives present themselves: 1. The rectum may be doubly ligatured below the disease and the cancerous segment removed, tied securely at each extremity; the remaining healthy mucous membrane is then everted through the anus. Or 2. The entire cancerous segment of the rectum, occluded above by a ligature, may be invaginated, *i.e.*, turned inside out and made to protrude through the anus. It is possible to do this if the growth is not bulky, and it is certainly to be recommended, as it enables one to thoroughly inspect the diseased area and make the lower section with ease and precision.

The temporary suture retaining the upper segment (Fig. 5) is now undone and one notes if the laxity of the latter is sufficient to permit of its being drawn down through the anus. If not, the fatty tissue behind the bowel may be still further divided, preferably by blunt dissection, and the peritoneum on each side of the mesentery snipped with scissors. While this is being done one should carefully examine for lymphatic glands, and remove any which may be felt or seen. Before drawing down the ligatured bowel

FIG. 7.—View of the completed operation. The sacral wound is not completely closed by suturing, but is left partly open and packed lightly with iodoform or xeroform gauze.

I shall now demonstrate to you some specimens of rectal cancer which I have removed by this method. As to the results you can judge for yourselves.

CASE I.—The first to which I shall direct your attention is that of an elderly man (J. H.) past seventy, who was sent to me by Dr. Hamilton, of Arklow.

has completely lost his cachectic appearance and is now in the enjoyment of excellent health.

CASE 2.—The next case is that of a woman, Mrs. L., æt. 65. She was transferred to my charge early in June last year by my colleague Dr. Finny. On examination I detected a soft cauliflower growth in the rectum, its upper limit being just within reach of my finger.

It was situated for the most part posteriorly, and was well above the sphincters. Some few days later I removed the affected segment of the bowel exactly as I have described. You will see in it (Fig. 9) another type of rectal cancer occasionally met with. A raised mass of cancer growth, for the most part flat on the surface, extends over a considerable area of the rectal wall. In some places its edges are prominent and overhanging, in others they slope away imperceptibly into healthy mucous membrane. Before undertaking the operation I was struck with the very free mobility of the rectum as ascertained by digital examination. The correctness of this observation I subsequently confirmed as I experienced but little difficulty in the actual excision and in the subsequent drawing down of the pelvic colon through the anal aperture.

You will notice an interesting fact on examining this patient, now twelve months after operation. She has developed a small hernial protrusion in the sacral region. This she attributes to a severe attack of bronchitis from which she suffered during the winter months, but it does not cause her much annoyance. On digital examination, as in the last case, you will detect a barely perceptible cicatricial ridge marking the line of junction of the two bowel segments. There is absolutely no evidence of stricture and she has perfect sphincteric control. I may mention also that she has gained considerably in weight.

CASE 3.—The third and last case which I purpose bringing under your notice to-day is that of an old man,

FIG. 8.—Cancerous growth involving the rectum removed by the trans-sacral operation. Case I.

Before his admission to hospital he had had increasing trouble in getting his bowels to act for several months. He experienced little pain, but an abundant discharge of clear mucus, which escaped involuntarily per anum and soiled his clothes, caused him great annoyance. On digital examination a large mass of growth could be felt; it extended to within about two inches of the anus, but it was possible to feel healthy bowel above it. The growth lay posteriorly, and did not interfere with the normal mobility of the rectum. It is now sixteen months since the excision was performed, and this specimen (Fig. 8) which I removed on that occasion represents a well-marked type of rectal cancer, *i.e.*, an irregular mass of cancerous growth projects prominently into the lumen of the bowel. The patient, who has been good enough to attend here to-day for your edification, is now in perfect health. On introducing a finger into his rectum you will detect a faint ridge immediately above the commencement of the anal canal which indicates the level of bowel junction. Observe that there is not the least evidence of stricture or narrowing here, and that the resistance of the sphincters is perfectly normal. He

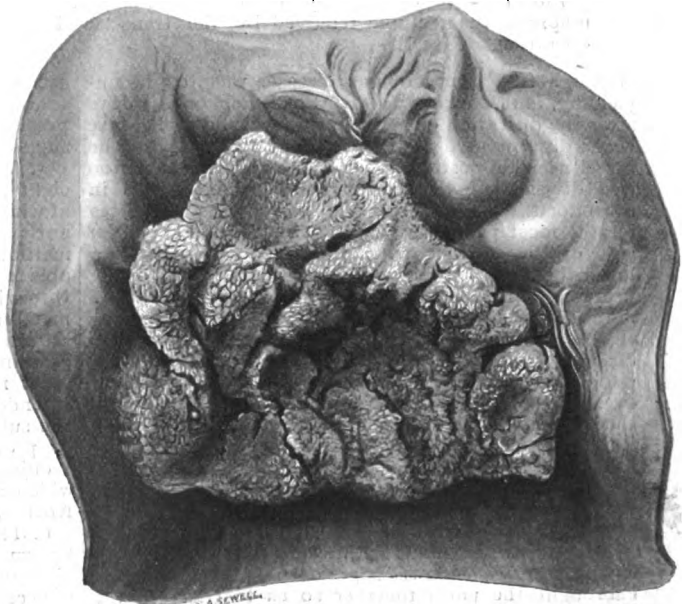

FIG. 9.—Cancerous growth of rectum excised by the trans-sacral operation. Case II.

N. S., æt. 72, who was sent to me from the out-patient department by Dr. E. J. Watson. On examination I found a hard mass of malignant growth extending completely around the rectum narrowing its lumen to a very marked extent. It is a good example of the annular type of cancer (Fig. 10). Such a growth is very apt to cause obstructive symptoms as it leads to stenosis of the lumen of the bowel of a progressive character. It is in such cases also that one is most likely to encounter difficulty in promoting a free evacuation of the bowels before operation. The upper part of the stricture in the present instance could just be reached by the finger, but it required an effort to do so. The mobility of the rectum was limited, but nevertheless it was sufficient to reassure me that excision was possible.

The steps of the operation, which was performed thirteen months ago, were precisely similar to those which I have described, but I experienced considerable difficulty in rendering the pelvic colon sufficiently lax to enable it to reach the anus as its mesentery,

FIG. 10.—Annular variety of cancerous growth involving the rectum, removed by the trans-sacral operation. Case III.

although free from obvious disease, was tough, unyielding, and loaded with fat. Some four or five days after the operation on removing the occluding ligature I was disappointed to find the lower extremity of the bowel necrotic posteriorly. This I attributed to a too free division of the hæmorrhoidal blood-vessels in my efforts to bring down the bowel. As the fæces for the most part from this time onwards escaped by way of the sacral wound, I decided to extend the latter through the sphincters into the anus. The healing process continued to progress satisfactorily, but I noticed that the upper bowel segment receded gradually, so that its discharging orifice came to lie hidden beneath the divided sacrum. A few months later the patient returned to me, complaining of want of control over the bowels, and a scalding sensation referred to the skin in the vicinity of the sacral wound. Yielding to his entreaties to do something to improve his condition I dissected the bowel free from its surroundings, opening the pelvic peritoneum in doing so, and drew it down without much difficulty to the anus, where I fixed it by sutures, having first vivified the parts here. Then, having pared and undercut the margins of the skin wound and freshened the edges of the sphincter behind, I brought the parts together so as to cover in the posterior aspect of the bowel and re-establish the normal condition of parts in this region. I am happy to say the result of this second operation has exceeded

my expectations. The patient, as he himself will tell you, is in a much more comfortable condition; his control, although not perfect, is nevertheless good, except after taking medicine, when the motions assume a liquid character. On examining the bowel with the finger you will find it quite healthy, and the anal region in a sound condition.

I had hoped to have had two other cases to exhibit to-day, in both of which the operative results have been most satisfactory, but as the individuals concerned live in remote parts of the country, I found it impossible to carry out my intention.

There are many points relative to the surgery of rectal cancer which I could not possibly include within the compass of a single lecture. You doubtless have heard of other operative methods, but time does not permit me to review them in detail. I shall therefore conclude by summarising the main facts which I would like you to carry away with you.

1. Of the cases of rectal cancer which come under observation, a comparatively small percentage is in my experience suited for excision. This is due mainly to the insidious nature of the disease, which enables it to make great headway before its presence is even suspected. I would impress upon you, therefore, the necessity for making a careful rectal examination in patients who come to you under the impression that they are merely troubled with hæmorrhoids, or who present vague symptoms of rectal discomfort.

2. Excision of the rectum should never be attempted unless the operator is quite certain that purgation of the intestinal tract has been thoroughly accomplished. Failure to observe this rule can only end in disaster and bitter disappointment.

3. Rectal excision is an operation which demands the most minute attention to aseptic details. As I have already explained one should aim at removing the diseased segment of the bowel without contaminating the large pelvic wound. Since adopting the method of operation which I have described my cases have recovered with remarkable rapidity, and the results as regards sphincteric control have in nearly all cases been most satisfactory.

4. The real key to a successful sacral or coccygeal resection of the rectum lies, I think, in opening early into the cavity of the peritoneum. This step can usually be accomplished in the way I have described; it enables one to get round the bowel quickly and with precision, and enormously facilitates the subsequent stages of the operation.

5. The retention of a ligature for at least forty-eight hours on the healthy bowel beyond the point at which it emerges from the anus, plays a most important part in promoting post-operative asepsis. This method of dealing with the bowel seems to me preferable to that of Kocher, in which the bowel is drawn down through the anus and sutured to the everted mucous membrane of the anal canal, the sutured parts being returned immediately within the anus. While readily granting that this is a great advance on some of the older methods, I cannot help regarding it as being attended by some risk, especially if one or more of the sutures should give way. The method of seeking to prevent this accident by dividing the sphincter I object to strongly, and this apparently is a detail which should not be overlooked in the procedure of Kocher.

6. I have not so far made any reference to what is known as the perineo- or sacro-abdominal method of operation for rectal cancer, as I consider it, as a rule, unnecessary when the disease lies within easy reach of the finger. This operation, I should say, finds its principal indication in cases of malignant disease in the lower part of the pelvic colon, and the neighbourhood

Dr. EARL's report: "The tumour consists of a stroma of very dense connective tissue, in which are alveoli of varying size, but generally small. These alveoli contain masses of small cells with round nuclei and a thin layer of protoplasm. The tumour has the general appearance of a carcinoma, though the cells are smaller than are usual in carcinomata. There are many parts of the sections from which no other histological diagnosis could be made than that of carcinoma. On further careful examination several appearances are seen which make it evident the cells filling the alveoli are derived from the endothelium of the vessels. It is possible to trace a connection between some of the alveoli filled with cells and normal small vessels, and, as is wellseen at A and B (see Fig. III.), a connection can be traced between the normal endothelium of vessels and the cells that fill the alveoli. In some of the vessels the endothelium has become cubical on part of the vessel, as at C (in Fig. III.). It is also worthy of note that even in alveoli in which the cells, as is generally the case, cannot be traced to the endothelium of vessels, the outer cells of each mass are cubical and form a fairly definite lining to the alveoli." The diagnosis is therefore endothelioma of the fundus of the uterus.

Clinical Records.

LIVERPOOL NORTHERN HOSPITAL.

Two Cases of Excision of Gasserian Ganglion for Neuralgia.

Under the care of DAMER HARRISON, F.R.C.S.E.,
Surgeon to the Liverpool Northern Hospital, &c.

CASE I.—J. G., æt. 45, labourer. Was admitted into the Liverpool Northern Hospital, March, 1893, having suffered from paroxysmal neuralgia on the right side for five years. The attacks had been of dreadful severity, recurring sometimes in the morning, sometimes in the evening, with varying periods of entire relief. At this time (1893) the pain was in the inferior dental and infra-orbital nerves, and the first operation consisted in opening the inferior dental canal and excising $\frac{3}{4}$ inch of the nerve, and stretching the infra-orbital nerve at its exit from the infra-orbital foramen. This operation was followed by immunity from pain for ten months.

The second operation was in November, 1894, and in this case all the steps for removal of the Gasserian ganglion by the pterygoid route were followed until the inferior division of the fifth nerve was exposed at its exit from the foramen ovale; it was there seized with forceps and torn from its connection with the ganglion. The middle division of the fifth was dealt with in the same way by means of a hook in the sphenomaxillary fissure. After this second operation there was immunity for nine months.

The last operation (July 10th, 1896) was removal of the Gasserian ganglion by Mr. Rose's method, and was difficult to perform in consequence of the guides to the foramen ovale having been removed at the previous operation. There has been no recurrence of pain since the ganglion was excised, now eight years ago.

CASE II.—J. B., æt. 40. Was admitted into the Northern Hospital in December, 1896, having suffered from increasingly painful attacks of neuralgia during the previous three years. The Gasserian ganglion was excised, with complete immunity from pain up to this time, seven years and eight months from the date of the operation.

The operation by the pterygoid route is dangerous and difficult, and certain objections may be urged to this route when compared with the temporal route which has been adopted in recent years. The wound leaves a disfiguring scar upon the face; there may be

necrosis of the zygoma, and the coronoid process may be lost. There is often severe bleeding from the pterygoid plexus of veins and from the internal maxillary artery. There may be difficulty in finding the foramen ovale, and danger of sepsis from accidental opening of the Eustachian tube.

These cases are of special interest from the long immunity from pain which I am able to report in each case—a longer period without recurrence has so far not been reported.

Transactions of Societies.

BRITISH GYNÆCOLOGICAL SOCIETY. MEETING HELD THURSDAY, JULY 13TH, 1905.

DR. WILLIAM ALEXANDER, President, in the Chair.

DR. CHARLES MAUNSELL read the particulars of an interesting case of

ENDOTHELIOMA UTERI.

illustrated by drawings and micro-photographs, which will be found under the heading of "Original Communications," page 83.

In the discussion that followed—

Mrs. SCHARLIEB, M.D., stated that she recently read notes of a case of endothelioma of the uterus, which was singularly like the one just described by Dr. Maunsell, both in its macroscopical and its microscopical characters. There was a large formation of new vessels, many new lymphatics, many of which were filled with cells. She would have much pleasure in showing the specimen and the slides on a future occasion.

Dr. MACNAUGHTON-JONES said that the Society was indebted to Dr. Maunsell for bringing forward this case. So far as he knew, no similar one had been as yet recorded. Endothelioma of the uterus was extremely rare. This was not the case with regard to the ovary, for Lange had collected, up to 1903, over forty cases of the latter. This was accounted for by the difference in the histology of the two organs. It would appear that in Dr. Maunsell's case the endothelial growth commenced not from the outer sheath, but from the inner or endothelial lining of the vessels. Of the two chief sources of origin, lymphatic and vascular, his case appeared to be of the latter.

Dr. SMALLWOOD SAVAGE proposed that the specimen should be referred to the Pathological Committee of the Society.

Dr. MACAN proposed that Dr. Maunsell's name be added to the Committee, and seconded Dr. Savage's proposition.

Mr. BOWREMAN JESSETT asked what were the contents of the tumour, and the patient's age?

Dr. BELL asked whether there were any early uterine symptoms before those narrated manifested themselves? Was there any discharge from the uterus, or had that organ been interfered with previously by curettes or otherwise before the patient came under Dr. Maunsell's care?

Dr. MAUNSELL, in reply, said he had to thank Mrs. Scharlieb and the others who had kindly spoken on his paper. Under the term endotheliomatous endometritis conditions were described, but he could not find a description of endothelioma occurring in the substance of the uterus, as that tumour appeared to do. He would be glad to have the tumour submitted to the Pathological Committee. In reply to Mr. Jessett, the cyst had been discharging for nine months through the sinus in the abdominal wall, and contained only pus and degenerated cells. Mr. Bell asked whether curetting had been done. There had not been any treatment at all beyond poulticing the swelling in the abdominal wall. She came to the hospital, from the West of Ireland, where she had no gynæcological treatment. The patient had poulticed the swelling herself until it burst.

Dr. MAUNSELL also read some notes on an improved method of

VENTRO-SUSPENSION OF THE UTERUS,
which we hope to publish next week with illustrations.

Dr. H. MACNAUGHTON-JONES: read a short paper on POST-OPERATIVE PAROTITIS, WITH NOTES ON CYLLIN AS A POST-OPERATIVE ANTISEPTIC which will be found on page 81.

In the discussion which followed.

Mr. W. CHARROTT LODWIDGE said he was responsible for the preparation which Dr. Macnaughton-Jones had just brought forward, because he first practically introduced it to the profession at large. When he first came to take up the substance as an intestinal antiseptic he helped Dr. Bousfield to discover what action it exerted upon the secretion of the bowels, and also on the bacteria of the bowel, and whether it had any injurious effect on the body. Thirty-six minims a day for eight days were given to a patient in the form of 3 min. palatinoids, and the faeces examined every day. At the end of eight days the number of the bacillus coli in the intestine was reduced by 97.5 per cent. The substance had produced no toxic effects whatever. He had used it in the case of young children, even as young as fifteen months of age, 6 min. a day, and there had been no trouble whatever. It was an oxidised hydrocarbon, having a diphenyl nucleus in place of the single phenyl found in carbolic acid and its homologues, Cyllin had antiseptic properties, which varied according to the bacterium for which it was used. For instance, it was thirty-four times stronger than carbolic acid for *B. pestis*, it was eleven times as strong for tubercle, and nine times as strong for the staphylococcus pyogenes aureus. Dr. Klein also suggested to him that it had a specific action on the white corpuscles of the blood. It not only destroyed the tubercle bacilli, but it induced an increased phagocytosis.

Dr. ROUTH considered that much depended on the condition of the mouth in the treatment of a great number of diseases. He had made it a rule in many cases, whatever the disease was, when the man or woman was losing his or her appetite and flesh, to turn his attention to the mouth, and almost always found the breath foul. Frequently after giving five drops of dilute carbolic acid all the symptoms disappeared in a day. Cyllin, he believed, was one of the best medicines of the same kind, because it was comparatively harmless, and almost any reasonable quantity of it diluted could be taken without injury. Certainly it was more powerful than carbolic acid, was much less dangerous, and as such it was a remedy which should be used in all cases for vaginal injections.

Dr. MACNAUGHTON-JONES, in reply, said that one of the most interesting matters connected with operative gynaecology was the occurrence of parotitis after such operations as ovariectomy, and similar pelvic operations.

[NOTE.—The remaining papers and discussion at this meeting will be given in our next.]

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, July 23rd, 1905.

A NEW TREATMENT OF WHOOPING COUGH.

NUMERLESS are the drugs given for pertussis. Amongst the new agents there appears to be one however, which may claim a certain efficacy—gomenol. According to Prof. Ausset, of Lille, this drug has succeeded in his hands in several cases of the most exaggerated type and where other agents had failed.

A child of 7 years of age had had the whooping cough already one month. A mixture containing grindelia, belladonna, valerian, produced no relief. Vomiting persisted in spite of large doses of antipyrine. The patient had from 30 to 40 attacks daily. It was at this period that injections of a solution of gomenol and oil (20 per cent.) were begun. The first day 10 cubic centimetres (2½ drachms) were injected, but the condition remained the same. On the third day the seizures were diminished by one third and the vomiting had

ceased. Improvement from that time was astonishingly rapid, for a week later the child had only five attacks, and twelve days after the first injection they had disappeared. The patient coughed a little still, and the injections were replaced by fumigations of gomenol and a fortnight subsequently the patient had completely recovered.

Another case was that of a child of 5. The family refused at first the injections and the child was given a mixture of valerian, belladonna and antipyrine without result. M. Ausset having warned the parents of the danger to the patient of whooping cough at that age, was authorised to practise the injections. He injected 5 cubic centimetres daily (1 drachm) of the 20 per cent. solution and at the end of ten days the seizures had fallen from 23 to 4 in the 24 hours. At this period the injections were suppressed and replaced by syrup of gomenol.

TREATMENT OF BOILS AND ANTHRAX.

The treatment of boils and anthrax is general and local. The general treatment is that of the cause, uric diathesis glycosuria albuminuria. Even when no special diathesis can be incriminated certain hygienic precautions, says Prof. Reclus, are necessary,—baths, frictions with a hair glove followed by spirit of lavender, internally beer yeast can be given with advantage to the digestive tract.

The local treatment is very simple. Pulverisations of a weak solution of phenic acid (1-100), lasting half an hour and renewed four or five times in the twenty-four hours. After each seance the antiseptic ointment, already mentioned in this journal, is applied.

As to the history, Prof. Reclus uses it rarely and only in one of three conditions. Where the pain is excessive when the tumour continues to extend in spite of the spray and where the boil is seated in dangerous regions, as the face or the upper lip, where meningo-cerebral complications might be feared.

When an operation is indicated, a solution of storaine in the case of boils, may be injected as a local anaesthetic. The needle should be inserted outside the inflamed region and pushed under the tumour, which becomes white; at that moment it can be opened largely without the slightest suffering and the pulverisations continued with the antiseptic dressing.

In cases of anthrax, which do not yield to the spray and the antiseptic ointment the thermo-cautery should be used in the place of the knife, and the patient put under chloroform. But, adds M. Reclus, cases of surgical interference are happily rare, for the great majority of cases, whether of boils or anthrax, yield to the simpler treatment above detailed.

Germany.

BERLIN, July 23rd, 1905.

At the Society for Innere Medizin, Hr. Hans Kohn showed preparation from a case of

GANGRENE OF THE LUNGS,

excited by a foreign body in the bronchus. The foreign body was a chicken bone that got into the bronchus in August last. The first symptoms were spasmodic cough, with purulent, and finally foetid, expectoration. The diagnosis was not clear at the earlier periods. The history was doubtful, no bronchoscopic examination was made, and when at last a diagnosis was made by aid of the bronchoscope, the gangrene had become extensive and the patient's condition had got so bad that there was no possibility of avoiding a fatal ending to the illness. The case was a warning that when there was even a remote suspicion of the presence of a foreign body in a bronchus, bronchoscopy ought to be resorted to.

Hr. A. Fraenkel observed that since the introduction of the bronchoscope admission of a foreign body into a bronchus ought not to be dangerous so long as proceedings were taken sufficiently early. The case before them came under his observation only in February last; there was then infiltration of the whole of

the lower lobe of the right lung. The patient stated that he believed he had got a piece of bone in his windpipe in August last, but his statement was not at all a decided one. He proposed the bronchoscope, but the use of the instrument was declined. The use of it, however, at that stage, and the discovery of the foreign body would scarcely have been helpful, as the bone had been there months already, and its extraction would not have averted the unfortunate termination. Moreover, the diagnosis appeared very uncertain for the following reasons:—

(1) There was already a rectal fistula that raised suspicion of tuberculosis; (2) tubercle bacilli were found in the expectoration, so it really appeared to be a case of gangrene of the lungs caused by the tuberculosis and the expectoration was putrid even then.

Hr. Edm. Meyer had seen the patient for the first time only two days before. He was then worn down and had fever, and was sent to him for bronchoscopy. The bronchoscope was introduced under cocaine, and was successful in showing a foreign body embedded in soft mucus, and lying in a bronchus of the third degree. On account of the distressful condition of the patient, however, it was not extracted. By means of the bronchoscope one could make quite certain that the case was not one of single large abscess, but that there were a large number of smaller ones scattered about so that there was no indication for surgical interference. Probably a timely use of bronchoscopy would have led to a favourable result. As it was not a dangerous procedure, it might be made use of on suspicion only.

Hr. Heubner observed that one of the assistants in his Klinik had succeeded in extracting a foreign body from the bronchus of a child after bronchoscopy months after it had been swallowed, and after it had set up putrid bronchitis, and that the child had made a perfect recovery.

At the Surgical Congress, Hr. Hackenbruch spoke on
THE TREATMENT OF INFANTILE PARALYSIS BY
NERVE GRAFTING.

He showed a child, *æt.* 13, whom a year and a half ago he had treated by implantation of nerve. There was paralysis of the peronei and extensor muscles. The tibial and peroneal nerves were exposed and a long strip from the tibial was introduced and fixed into the sheath of the peroneal. Recovery was uninterrupted. After four and a half to five months distinct movements of abduction could be seen; the muscle was not movable electrically. Now, after a year and a half, the function was perfect, the muscle responding to both galvanic and faradaic currents.

Hr. Rehn spoke on

TUMOURS OF THE BLADDER AMONG ANILINE WORKERS.

He had already reported on twenty-three cases of such tumours at the last Congress. He now showed a preparation from a man, *æt.* 50, who had worked at aniline works for eighteen years. He had bladder troubles, and had the high operation performed for tumour of the bladder a year ago. Recovery was slow, but in the end the patient was discharged free from trouble. In January of the present year, he got hæmaturia, bladder disturbance, and in February retention of urine. There was recurrence of the disease, and an operation was again performed which was very difficult. The high operation was again done, and the bladder was also entered from the perinæum. The patient died six weeks afterwards. The autopsy showed carcinoma of the right kidney and of the right ureter. The preparation showed that the cancer of the kidney was the primary lesion, that the disease had not reached the ureter along the lymph track. The symptoms due to the bladder disease had therefore masked those of the kidney mischief.

VIENNA, July 23rd, 1905.

CONGENITAL DEFECT IN SEPTUM VENTRICULORUM.

At the Gesellschaft für Innere Medizin, Drey showed

a child, *æt.* 3½, who was cyanotic when nine months old, and then observed to be rachitic. In its history it had chicken-pox and several times inflammation of the lungs.

About the beginning of February the following conditions are recorded on its reception into hospital:— An imperfectly nourished child, with a rachitic thorax. There is no cyanosis, nor dyspnoea to be observed, but a distinct tendency to drumstick fingers was present. The left side of the chest was quite vaulted, but no "fremissement" nor pulsatio epigastrica.

Percussion gave dullness below the third rib extending to the middle of the sternum towards the right, and the anterior axillary line to the left. The apex beat was in the axillary line with a loud blowing systolic murmur, loudest over sternum and third left intercostal space, where the sound was harsh and grating; the second sound was loud and strong on closing, which could be heard along the pulmonary artery. The pulse was small and regular; no rising of the vessels in the neck, and no pulsation could be detected in the jugular vein.

The Röntgen rays only tended to confirm the clinical examination, particularly the cardiac area of dullness. It may be mentioned that a few glands about the size of peas were detected over both clavicles, as well as both axillæ, with a few large rales in the bronchi.

With these complex phenomena he was inclined to reserve judgment, but considered it one of septal defect with insufficiency of the mitral valves.

Hochsinger said that he had seen this little patient in its fifth month, and thought there was no mistake about the diagnosis of a serious defect in the wall of the ventricle, but there certainly was a little mystery about the disappearance of the cyanosis on admission to hospital. He thought this might be explained by the higher pressure in the left ventricle, even with a defective septum, where the blood would be pressed from left towards the right side and not *vice versa*, as occurred when the patient was younger, and when the cyanosis was present.

ADENOID VEGETATION.

Spieler showed four patients from the Ambulatorium of the Carolinen Hospital, whose ages ranged from eight years to thirteen years, with bilateral exophthalmia associated with vegetation on the tonsils. He contended that this combination was more common than Holz would accept. Within a very short period he had met with a number of these cases, but would not venture to theorise on the cause of the exophthalmia, although it subsided after removal of the adenoid from the throat. One of the cases presented had recently been curetted and the testimony of the mother and friends was that the ophthalmia was now much less. It would seem from this that some connection exists in the etiology of the disease, probably due to the adenoid first causing a hyperplasia in the throat which may act on the lymphatic circulation and subsequently cause a congestion of the retrobulbar lymphatic that may lead to the exophthalmia. This is only presumption, but such an anatomical connection may be established.

Among his cases were a few "tower crania," which show deformity in this direction, but such skulls usually have no influence on the production of exophthalmia.

RHINO CLEROMA.

At the Gesellschaft, Freund showed a case of a man who came to him on April 19th, with an intractable rhinoscleroma. He immediately commenced the Röntgen rays with six minutes' exposure at a time.

Making no improvement, the treatment was stopped and recommenced after a long pause. This was repeated three times so that the whole treatment of twenty-three exposures may be divided up into four series, which resulted in an increase of the pigment, but no visible change in the tissue.

The rays were finally given up as inoperative, but, strange to relate, shortly after stopping the rays the nose began to soften and the infiltration to disappear.

The upper lip is still a little thickened, but the face and nasal orifices are quite free, permitting the patient to breathe freely, which he could not do before.

RELATION OF CARDIAC VOLUME TO PULSE.

Heitler reminded the members of his experiments on animals in 1889 to prove that the heart was altered in volume immediately the pulse was altered and *vice versa*. Shortly after these experiments his attention was directed to arrhythmia, which further proved his experiments on dogs to be correct.

His latest experiments were on the human heart by acting on the pulse through continued pressure over the region of the liver or upper ribs of the chest. This mechanical operation so acts on the pulse that its effects can readily be observed on the heart. This enlargement of the heart when the pulse is reduced has been verified by the Röntgen rays as well as by percussion, and is now proved to be an indisputable fact which ought to enter into our calculation in morbid anatomy.

The exact measurements of the shadow with 60 centimetres of focal distance varied between 0.5 of a centimetre to 1 centimetre; one of his measurements exceeded 2.7 centimetres. The increase of breadth is more frequently on the left side than the right, and is as often upwards as downwards.

Bungary.

FROM OUR OWN CORRESPONDENT.]

BUDAPEST, July 28rd 1905.

At the last meeting of the Hungarian Gynaecological Society, Dr. Tuszkaï Odón read a paper on **HYPERÆMESIS GRAVIDARUM—A GASTRO-INTESTINAL AUTO-INTOXICATION.**

In 1897 Dirmoser first 'enunciated' his theory that hyperæmesis gravidarum is an auto-intoxication due to the absorption of putrefactive products of albumin, such as indol and skatol, from the gastro-intestinal tract. It has received support from the work of Albu, Kraus, Nothnagel, Taksch and others.

From analyses of the urine in thirty-six severe cases up to 1904 it was found that: (1) the excretion of urobilin was abundant in all; (2) blood colouring matter was present in four cases; (3) albumen was present in small amount in all, and often varied with the severity of the attack; (4) acetone was found four times; (5) peptone was found thrice abundantly, once a trace only; (6) oxalic acid was usually increased; (7) indoxyl and skatoxyl were almost always increased; (8) urinary sediment was always abundant, it thrice contained hyaline and granular casts, and often blood corpuscles, fatty epithelium, and numerous crystals of triple phosphates, sodium urate and calcium oxalate. Dr. Tuszkaï concludes (1) that the products of metabolism, normally excreted such as indol, skatol, and ethyl-sulphates, are found in increased amount in these cases; (2) that abnormal constituents, namely, albumen, urobilin, acetone, and peptone occur in the urine; (3) that acute nephritis may occur. A similar condition of the urine and kidneys is found in many acute infectious diseases, such as the diarrhœas of children, Asiatic cholera, ileus, &c., and are due to the stimulation of the kidneys by poisonous products absorbed from the bowel.

Only a few necropsies are recorded. There is usually atony of the intestinal tract, and slowly swelling and fatty degeneration of the liver and kidneys. Should this auto-intoxication theory be correct, intestinal disinfection is indicated.

INTRACTABLE VOMITING OF PREGNANCY.

Dr. Révész Vilmos said that the gravity of the vomiting does not altogether lie in its intensity or its frequency, for pregnant women often vomit after each meal, apparently all the food, without serious impairment of nutrition and with little or no loss of weight. On the other hand, in intractable vomiting not only is the digestive function perverted, but nutrition is very rapidly and profoundly altered; the complexion becomes waxy, the skin dry and scaly, and the epidermis cracks. In primiparæ intractable vomiting is more

common in the second and third months, in multiparæ in the fourth. In the former the symptoms progress more rapidly than in the latter; not only does the vomiting immediately follow the ingestion of a spoonful of fluid, but there is a constant sensation of nausea, and continual futile and extremely painful attempts at vomiting are made. The writer recognises as causes two conditions: hysteria and auto-intoxication. Treatment differs accordingly. Either may be fatal.

What signs show the necessity of inducing abortion? Oliguria and progressive and continued loss of weight are of the greatest importance. If, in spite of treatment malnutrition is rapid and continued, the question must be raised. Expulsion of the ovum may take from one to ten days, but its death alone leads, if not to cessation, to diminution of the vomiting. In one case the patient was able to retain a glass of milk six hours after the introduction of a sound, though the ovum was not expelled. This fact shows the value of dilating the cervix, but in a primipara digital dilatation in the second or third month is impossible; then laminaria should be used.

Operating Theatres.

ROYAL FREE HOSPITAL.

OPERATION FOR REMOVAL OF A THYROID ADENOMA.—

Mr. T. P. LEGG operated on a woman, æt. 49, who for the last two or three years had noticed a swelling in the lower part of the left side of the neck. The swelling had slowly increased in size and was now as big as a tangerine orange; it had caused some shortness of breath and a little discomfort on swallowing. The swelling was situated in the left lobe of the thyroid; it moved up and down freely on swallowing; it was globular in shape, very elastic and smooth on its surface. The trachea was pushed over a little to the right of the neck. Examination of the larynx showed that both cords moved freely; there was very slight enlargement of the right lobe of the thyroid. A transverse incision two and a half inches long was made over the lower part of the swelling. The deep cervical fascia and the platysma having been divided, the supra-hyoid muscles were separated from one another in a vertical direction and held apart by retractors; the tumour in the thyroid was then exposed and was found to be covered by a thin layer of thyroid gland tissue; this was carefully divided till the tumour itself was reached. A thyroid scoop was next passed in between the capsule and the tumour, which last was then readily enucleated except where the vessels entered it on its deep aspect; these were clamped before being divided, care being taken to keep as close to the tumour as possible. The vessels were then ligatured and the cavity in the gland was sewn up by a couple of purse-string sutures. The muscles were then replaced, the cut edges of the platysma united, and the skin incision closed by a continuous silkworm gut suture. Examination of the tumour showed it was a typical adenoma of the thyroid; it was solid throughout and composed of ordinary gland tissue. At one part there was a small mass of calcareous material which Mr. Legg said was not uncommonly found in old-standing goitres, especially in elderly people. He pointed out also that there were two chief varieties of innocent thyroid tumours—the first, in which the whole gland becomes enlarged, this is called a parenchymatous goitre; and the second, in which definitely enucleable tumours (adenomata) are formed. The present case, he said, was a good example of the latter variety, and the importance of clearly distinguishing these two forms arises from the fact that the operative treatment of the two varieties is different. In the parenchymatous goitres extirpation of one lobe

after ligation of the vessels is required; in the case of adenomata enucleation, usually a much less serious proceeding, is the treatment. Mr. Legg remarked that the diagnosis could generally be made by noticing the shape of the tumour, which is globular in adenomata, as well as by the trachea being displaced to the opposite side by the growth; it is not so important, he thought, to diagnose cysts in the thyroid tumours, because cysts are very often due to degenerations in adenomata, as it is to distinguish parenchymatous from adenomatous goitres because cystic adenomata are treated like the solid adenomata. As regards the operation itself, he said that the transverse incision is always to be preferred, as it leaves much less scarring. Two other points in the operation, he remarked, are of importance—first, to recognise and divide the layer of thyroid tissue overlying the tumour, and to make certain, therefore, that one has got into the layer of suppuration between the tumour and its capsule; if this layer is clearly recognised the tumour shells out without any difficulty. The other point is the hæmorrhage, and as this is usually venous and the veins are often very big, unless obvious veins are avoided the amount of blood lost may be very great. It is, however, generally at the last step of the enucleation, he pointed out, that hæmorrhage takes place, and it can generally be controlled temporarily by plugging the cavity and subsequently tying the vessels. It is a good plan, too, he thought, before the incision is sewn up, to allow the patient to come round partially from the anæsthetic; the straining thereby induced will often cause a vessel to bleed freely which had before been collapsed. A minor point, he considered, is to sew up the infra-hyoid muscles if they have been divided, and to unite by three or four stitches the cut edges of the platysma. This latter step brings together the margins of the skin incision and enables the surgeon to remove the skin stitches on the fourth or fifth day without there being any risk of the wound opening up. In some cases where the cavity left is large, it is advisable, he thought, to put in a drainage tube for twenty-four hours. The indications for removal of thyroid adenomata, Mr. Legg said, were, first and foremost, dyspnoea; sometimes small adenomata, especially when situated low down, will give rise to considerable dyspnoea. Another important indication is displacement of the trachea, and a third indication increase in size of the tumour, especially rapid increase in size, which suggests cystic degeneration with possibly hæmorrhage into the cyst. In elderly patients the possibility of the occurrence of malignant disease should be borne in mind in thyroid tumours, which rapidly begin to grow.

Seven days after operation the patient left the hospital perfectly well. The stitches were removed on the fourth day.

THE report of the National Society for the Employment of Epileptics, which was adopted at the twelfth annual meeting of the Governors, shows that at the end of the year 1904 the accommodation at the Colony of Chalfont had been raised to 198 beds, distributed in the various houses or homes.

THE Lord Mayor has received a cheque from the Chief Rabbi for £1,161 19s. 7d., being the amount collected in the various synagogues of London, in addition to the collections already received from the West End Synagogue (£269) and the Spanish and Portuguese Synagogue (£180). The total of the Hospital Sunday Fund is now nearly £60,000, to which Mr. George Herring will add about £12,000.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, JULY 26, 1905.

THE INFANTILE MORTALITY.

THERE is no greater blot upon our boasted modern civilisation than the excessive infantile mortality that year after year is recorded by the Registrar-General of the United Kingdom. Among a certain class of popular writers the subject is wrought up with lurid extravagance of literary treatment, but it may be doubted whether they do more than justice to the case. What words can describe adequately the appalling waste of infantile life that acts as a constant drain upon the resources of the nation? Some persons argue that intellectual methods should be exercised to curtail the production of children, while others condemn with the utmost indignation any measures that check the natural growth of population. But whatever view we may take as to the moral issues involved in the procreation of children there can be none whatever as to the necessity of putting them under favourable conditions of environment, so as to secure a maximum survival of the infantile population. The question of the excessively high infant mortality rate and the means of remedying it were ably discussed in a paper read last week by Dr. George Carpenter at the London Congress of the Institute of Public Health. The Registrar-General's Returns for 1904 show that the average death-rate for the 76 great towns of England and Wales was 17.2 per 1,000 living, while the rate for infants in the first year of life was 160 per 1,000 births. In 142 other towns the infantile rate was 154 per 1,000, and for rural England and Wales 125 per 1,000. Certain other large towns showed a still higher rate. Thus, Birmingham had 197; Liverpool, 196; Stockport, 203; Hanley, 212; Preston, 218; and Burnley, 229. In London the highest borough rate was Bermondsey with 172, and the lowest Marylebone with 94. The infantile mortality rate in various wards of Birmingham has been shown to be no less

than 331 for St. Mary's and 263 for St. Bartholomew's. These and other startling statistics that might be quoted demonstrate a position of affairs with regard to the infantile mortality rate that may be regarded as a standing menace to the future prosperity of the country. One of the most disquieting features of the situation is that the waste of life is due to a class mortality, that is to say, it is practically confined to artisans and poor classes and does not exist to any extent in the middle and upper classes. In view of the diminishing birth-rate the more or less stationary figures of the total population assume a position of extreme importance. Most medical men will agree with Dr. Carpenter's proposition that improper feeding is the main factor in the excessive infantile mortality. That statement becomes practically self-evident in the light of the further information that three-fourths of the deaths of children under twelve months of age occur among those who are bottle fed. Most medical men, also, will agree with the author's contention that the remedy for the present disastrous state of matters must be sought in the provision of a sufficient supply of pure cow's milk to the poorer classes of the community. The suggestion of cow's milk is, of course, intended only for children whose mothers for some reason or other are unable to feed them from the breast, as intended by all-wise and unerring nature. In fact, Dr. Carpenter comes round to the necessity of a municipal supply of sterilised milk, to be supplied on easy terms to the poorer population. As the same time he advocates a general stiffening of the regulations under which milk is produced and distributed. It is not within the province of the present remarks to analyse the article above quoted. Those who are interested in the subject will do well to acquaint themselves at first hand with the views of an author who has long ago established his name as an authority in infant feeding. It might be mentioned in passing that a French apparatus was described in another section of the Congress, the *Salvator*, which was said to be able to sterilise milk rapidly in any quantity. If that be so, the problem of municipal milk supply will be greatly facilitated. It is to be hoped that ere long the public conscience will be aroused as to the massacre of infants that is going on daily in its midst. Meanwhile the patient, self-sacrificing labours of scientific men are doing much to unravel the thousand-and-one perplexing coils beneath which this great and vital question is for the present well-nigh hopelessly hidden.

MUNICIPAL MILK

To preach to medical men the virtues of a healthy milk supply is to preach to the converted, but, unfortunately to the outside public the voice is as one crying in the wilderness. The excellent societies and guilds that make it their business to try to improve the conditions under which workers live have this subject much at heart. It is important, however, in every fight to measure the prowess of one's adversary, and when one contemplates

the forces arrayed on the side of the dairy interest, it is hardly surprising that little progress is made. A peculiar difficulty lies in the heterogeneity of these forces; no one organisation is concerned, but many of different types and calibres. The temperance reformers find the trade they attack one self-contained entity, but milk-reformers are denied that privilege, and have to attack their foes in detail. The farmer apologises for his faults by pointing at the railway companies; the railway companies blame the dairy companies; and the dairy companies hark back to the farmer. Consequently a vicious circle is formed which it seems as difficult to break as it is to fix individual responsibility under the cunningly devised system prevalent at the War Office. Eyes naturally turn to the public authorities charged with the execution of the Dairies, Cowsheds, and Milk Shops Orders of the Local Government Board, but admirable as the intentions of these orders are, they are notoriously limited in scope and clumsy in practice. In most parts of the country the orders are wielded with so tender a hand that they are practically a dead letter, and even when administered with some vigour, as in certain larger towns, their operation is found to affect but the fringe of a great question. It is in fact becoming increasingly evident that if the milk trade is to be placed on a satisfactory basis—that is, if pure, fresh, uncontaminated milk is to be available at a price within the reach of the poorest, an effort of far greater force and effect than anything yet attempted will have to be put forth. Such an effort can be directed at its objection in one or two ways—either by a frontal attack or by a flank movement. To adopt the former a storm of public indignation and determination would have to arise in such force as to carry all before it. Dairymen and dairy companies will have to be attacked by every process of law and public opinion till they capitulate without discretion, and find for their clients farms where sanitation is above reproach and cows are groomed with the attention given to race-horses, with vessels sterilised and sealed throughout the whole course of their wanderings, a railway service providing cool and rapid transit by train, and honest retailers and distributors, who have either no opportunity of diluting or adulterating the milk, or no interest in doing so. In spite of all that has been written and said on the subject, we fail to discern any indication of such a storm on the horizon; the sleeper merely stirs when roused, and turns uneasily on to the other side. The second method of which we have spoken, namely, that by flank movement, is the one to which indications at the moment point, and it is the one which is most in consonance with the present trend of affairs. By flank movement we mean a gradual replacement of the private vendor by the municipality. Liverpool, Battersea, St. Helen's, and Bradford, to name only some of the leading towns, have of late years established milk-depots for the supply of sterilised milk to the poor

under the tutelage of their sanitary committees, and though such enterprises are doubtful commercial ventures, these towns claim a sensible reduction in the diarrhoea death-rates among the infants fed with their milk. At Rochester, in the United States, an elaborate and carefully managed municipal milk-supplying system has been set on foot, and every detail in connection with the production and distribution is worked out in careful fashion, but the municipalities in this country have so far had to content themselves principally with obtaining ordinary commercial milk and sterilising it for themselves. The drawbacks to such a plan are obvious, and there can be no doubt that the next step will be towards the Rochester plan, whereby the municipalities own their own farms and are responsible for the whole milk traffic. Now, municipal trading is strongly opposed by a large section of the community, but in the case of a necessity as vital to the well-being of the nation as milk is, political inexpediences are preferable to physical detriment, and if the future brings forth the municipal milk-can and the half-yearly milk-rate, the apathy of the public will have itself only to thank. The purveyors of water, gas, traction, and electricity have, by default, found these enterprises pass from sources of private profit to themselves into the property of the public, and if the milk trade makes a similar change of allegiance, there will not be many tears shed by hygienists. That milk produced under ideal conditions can be supplied at a profitable rate has been shown at York, and again at Copenhagen, where a private company pays a 5 per cent. dividend in spite of its additional expenses. There should, therefore, be no reason on the score of expense why the supply of milk should not pass into public hands. In the meantime, with all the horrible reports of filth and disease connected with milk constantly coming to hand, the only avenue of safety lies in sterilisation. This process can be admirably carried out by the Salvator apparatus, as announced at last week's Public Health Congress in London, without any noticeable change in the quality or flavour of the milk, and the immunity it confers is absolute.

Notes on Current Topics.

Personation of a Medical Practitioner.

A REMARKABLE case of personation has recently come to light at Gravesend, when last week a man was charged before the magistrates with forging a death certificate and committing perjury. A few weeks ago, Walters, who was a stranger in the town, called on a Mrs. Cohen, wife of a tradesman, and attended her on the representation that he was a qualified practitioner. Mrs. Cohen subsequently died, and Walters gave a certificate stating that death was due to pneumonia. Owing to certain suspicious circumstances attending the death an inquest was held. Walters attended as a witness, and said he was the person mentioned in the *Register* as Arthur Peacefield Walters, M.R.C.S.

L.R.C.P., of 11, Beaufort Road, Clifton. He received a guinea for attendance, and signed the receipt. At the magisterial inquiry the real Arthur P. Walters appeared and stated that he was now practising in Scotland, and the address in the *Register* was that of his sister, given while he was travelling abroad. His diploma as well as three letters and his birth certificate, found on the prisoner, were at one time his property, and he was not aware he had lost them. He did not know accused and could only surmise he must have sent in the documents when applying for some post or other and that they had not been returned. It is not a little disquieting that that gross personation of this kind should have been disclosed by the merest accident. The General Medical Council, whose duty it is "to look after the *Register*," adopts no precautions whatever to guard against personation. A systematic inspection of signatures of death certificates would doubtless reveal similar abuses. Some day perhaps the Medical Defence Union, our ever present refuge and hope, will confer upon the profession the immense boon of a systematic record of names of persons who sign death certificates. Somerset House might possibly help.

Inebriate Reformatories.

THE inebriate reformatory is still more or less on its trial, and there are not wanting critics, lay and medical, who have not much faith in its future. Certainly its task is not a very hopeful one under the present state of the law and in the prevailing temper of certain magistrates. Before the inebriate reformatory is condemned it should be given a fair trial, for it is not often that it gets inmates whose condition can reasonably be regarded as capable of real amelioration. In Dr. Branthwaite's Report under the Inebriates Act he relates the case of a stunted, imperfectly-developed woman of forty-three who had been before the police courts 219 times for the following offences:—Drunkenness, with or without disorderly conduct, 180 times; assaults, 10 times; larceny, 9; wilful damage, 12; prostitution, 6; causing obstruction, 1; offence against the Licensing Act, 1. Her first conviction was at the age of seventeen, and altogether she had been convicted 198 times and had spent over sixteen years in prison. She was then sent to a reformatory for two years, and on her release relapsed into the old life. The futility of expecting a reformation in such a character in two years must be obvious to the meanest intellect. On the other hand, the case is quoted of a younger woman who gave way to drink, and was convicted three times in the course of four years, and finally sent to a reformatory for three years' detention. This woman since her release has been living a sober, industrious life, and has not touched liquor since. Dr. Branthwaite pleads for cases to be sent early in their career and for long periods, before the expedient of short police court sentences has degraded and hardened the offenders. The

reformatory, to be a success, must be treated fairly by committing authorities, and not looked upon as a *dernier ressort* for the hopeless drunkard.

"Bile Beans."

SOME interesting revelations were made in the action taken last week by the Bile Bean Manufacturing Co. to protect the title "Bile Beans." It appears that this well-advertised nostrum is put on the market by two gentlemen named Gilbert and Fulford, who apparently constitute the "Manufacturing Co.;" and is made from a formula drawn up by the latter gentleman. He is the "Charles Forde" described in advertisements as "a great scientist," although his partner was obliged to admit that, as far as he knew, Fulford had no scientific training whatever, unless a few years' work behind a druggist's counter was to be so designated. Of other training or study in chemistry or *materia medica* in any university or school he had none. Of an extract from an advertisement which referred to Captain Cook's discoveries in Australia, and his observation of the healthiness of the natives there, which was due to the medicinal properties of the indigenous plants, and Charles Forde's idea that these plants might be made useful to civilised men and women, Gilbert had to admit that there was nothing authentic but the reference to Captain Cook. He declined to say whether Australian plants entered into the composition of "Bile Beans," but neither he nor his partner had ever made any extensive inquiry into the medicinal properties of Australian herbs. Much stress was laid by the proprietors on the peculiar and ingenious shape of their product, so that they must have been taken aback when the presiding judge compared its appearance to that common object of the barn floor which indicates the vicinity of the ordinary rat.

Sterilisation of Degenerates.

ALTHOUGH the reception generally accorded to Dr. Rentoul's proposal to "sterilise" those harmful members of society who hand down their vicious traits to their offspring, was, and still is, a cold one, we notice that the seed he has sown has not fallen altogether on stony ground. In the Annual Report of the Gloucester and County Lunatic Asylums, the medical superintendent, Dr. Craddock, in speaking of the increasing amount of accommodation that is necessary for the insane in his county, warmly advocates some system by which physical means should be used to prevent the unfit from producing children. Dr. Craddock is much impressed with the influence of heredity in the production of insanity, and also with the increasing hopelessness of the cases that come under his notice. With these facts constantly before his eyes he urges that duty lies in the use of measures for the prevention of insanity quite as much as, if not more than those of attempted cure, when cure is so remotely to be hoped for. He fears that public opinion is not sufficiently advanced to adopt Dr. Rentoul's remedy, and he

sees but one possible alternative, namely, the life-long segregation of the unfit. The cost to the community of the latter plan would naturally be immense, if we accept Dr. Rentoul's carefully collected figures. These show that one in fifty of the population of the country is mentally degenerate, and no less than one in five is physically diseased—or undeveloped. The whole subject bristles with difficulties and prejudices, but we hope that the Royal Commission on the Care of the Feeble-minded, which is now sitting, will find some way by which imbeciles and half-witted girls can be prevented from bearing illegitimate children to unknown fathers in the appalling way that they do now. If a beginning could be made with this unfortunate class, the larger question might be gradually attacked.

The Psychology of Anæsthesia.

TWO centuries ago it was a moot question among philosophers, "Does the soul always think?" Though apparently the question was quite satisfactorily answered in the negative, at the present day again it may deserve consideration. This is due particularly to the fact that during recent years, with the discovery of the large field of sub-conscious psychological phenomena, the appeal to consciousness loses its finality in answering questions in psychology. There is, indeed, in modern psychology no more interesting branch than this of the sub-conscious, and it may be argued with show of reason that sub-conscious psychological activity is always present, and consequently that "the soul *does* always think." Whether this be so or not we leave to the philosophers and psychologists, but the latter have recently requested the assistance of physicians in the study of a point which may have some bearing thereon. Professor Jastrow, who occupies the Chair of Psychology at Wisconsin, suggests that a useful series of observations might be made on persons undergoing anæsthesia for surgical purposes, particularly in the process of "going under" and "coming to." He suggests certain details on which information might be gathered, such as the degree of suggestibility of the patient, and the possibility of the production of automatic acts during light anæsthesia. The observation of such phenomena as automatic talking, mechanical acts, tricks of manner, and so on, may give some help in the elucidation of the processes of sub-conscious psychological activity. The recollections of an intelligent and instructed patient of his own experiences would also be of use. We have no doubt that there are many practising anæsthetists who would be glad to co-operate with Professor Jastrow in the interesting research he suggests.

Liquid Air.

SINCE the discovery of the liquefaction of atmospheric air, but few attempts seem to have been made to use the fluid in the treatment of disease. In the *Medical Record* for July 8th there is a suggestive paper by Dr. William Trimble, of New York

on therapeutical applications of liquid air in dermatology. The conditions in which he has used it are chiefly those in which other measures have been disappointing or inapplicable. Five cases of pigmented mole are recorded, in all of which the result of the treatment seems to have been satisfactory. The liquid air is brought to the clinique in a Dewar's tube, and it is applied to the part to be dealt with by means of a swab of cotton-wool fixed on to a long stick. Varying degrees of pressure are used in applying the air and for various lengths of time. Light pressure causes slight reaction and inflammation; medium pressure, ulceration with superficial sloughing; hard pressure, deep sloughing. The part touched is instantly frozen and becomes quite hard, and if medium or hard pressure is used, obliterating endarteritis with necrosis of the tissue is brought about. Scarring to a greater or less extent results, but if the applications are infrequent and spread over a long period of time, the scarring is reduced to a minimum. The liquid, from its intensely low temperature, acts as an anæsthetic and no pain beyond slight tingling and burning is felt. Two cases of epithelioma of the face are related; the first of these healed completely after two applications; the second, which had failed to respond to X-rays, was cured by one. Two patients suffering from nævus vasculosus (strawberry mark) and two from lupus erythematosus did well, but their cases had not all been completed at the time of report. There would seem to be little doubt that in liquid air we possess a medium whose usefulness is well worthy of further investigation.

The Fourth of July and Tetanus.

THE returns of accidents due to Fourth of July celebrations in the United States have not yet come to hand, but we hope that the number of fatalities may show a decrease corresponding to what was noticed last year. In 1903 the number of persons killed as the result of firework celebrations on the Fourth was 466, while in 1904 it had fallen to 183. There were in each year in addition about 4,000 cases of serious accidents not resulting in death. The decrease in tetanus, too, was considerable; in 1903 there were 415 fatal cases reported, while last year there were only 105. There is no doubt that this improvement is due in great part to the energy of the medical papers of the States in preaching a crusade against the blank cartridge, the special engine in the production of tetanus, and in instructing laymen and medical men alike in the steps that must be taken to avoid the disease. Formerly, the wound of the palm caused by a blank cartridge was in most cases treated by household dressing, and even if submitted to a surgeon it received little more attention. It has, however, been impressed on the surgeon that all wounds such as may give rise to tetanus must be thoroughly cleansed to their depths, and on the part that the

aid of a surgeon should in all cases be invoked. The greater attention, however, given by parents to the dressing of wounds, in cases where a surgeon's assistance is not called in, has had its drawbacks. Very often excessively powerful antiseptics, such as strong solutions of carbolic acid, have been employed, to the great damage of children's hands, gangrene having ensued in several cases. It is unfortunate that a great nation cannot celebrate its festivals without the sacrifice of children's limbs and lives, but we hope that, owing to better instruction, the holocaust may this year again show a diminution.

Pathology of Cerebro-spinal Meningitis.

THE recent epidemic of cerebro-spinal meningitis in Silesia has afforded plenty of material for the study of this little-understood disease, and a report by Westenhöffer, which appears in the *Berlin Klinische Wochenschrift* for June 12th, contains some interesting observations. The most important of these has resulted in his being able to trace the path of infection, which is still held in much doubt by competent scientific Americans who have had the opportunity of making pathological researches on those who have died of the disease. Westenhöffer asserts that the posterior nares and especially the pharyngeal tonsil, are the paths of entry, and that by infection of the lymphatic and basic meningitis, starting in the region of the pituitary body, is set up. He holds that the meningitis rarely or never arises through extension of the inflammation from the ethmoidal cells. The disease, therefore, is contracted by inhalation of the organism; the patients are chiefly children. He found the diplococcus intracellularis meningitis in most of the cases he examined, but many other cocci were associated with it, and he does not consider the evidence of Weichselbaum's organism being the only, or even the chief, causative agent as conclusive. With regard to prevention, Westenhöffer points out that as the disease is one contracted by inhalation, the principal measures to combat it are those which aim at rendering the interiors of the houses clean and healthy. Grawitz, in the same journal, enters a protest against the name "epidemic" cerebro-spinal meningitis being used for a disease whose manifestations are chiefly sporadic, and suggests the term infectious or contagious meningitis. The latter are certainly more accurate, and have the additional advantage of not being cumbersome.

Criminal Charge Dismissed.

THERE seems to be no end to the monstrous charges which people prefer against medical practitioners, and the only satisfaction that can be derived from the contemplation of them is that juries have the good sense to see through these worthless actions. At the Winchester Assizes, on the 6th and 7th of this month, the trial of an action against a Gosport doctor for damages for seduction was heard before Mr. Justice Bigham.

The case had been tried previously, but upon that occasion the jury had been unable to agree. The plaintiff was a fishmonger, and his daughter alleged that after two operations had been performed on her throat by the doctor, she paid him several visits at his surgery. During these visits the defendant made overtures to her, and finally seduced her. A further suggestion was made that the doctor had given her certain drugs when he was informed that she was pregnant. These drugs had been analysed and were found to contain nothing more harmful than magnesium sulphate and myrrh. The plaintiff's daughter's evidence was uncorroborated, and after hearing the opening remarks of counsel for the defence and the doctor's formal denial of the charge, the jury stopped the case. The judge, in giving his verdict for the defendant, said that he quite agreed with the view the jury had taken. However careful a doctor may be, it is always open to malicious and unscrupulous females to invent charges of misconduct, and it is of the highest importance to the honour and dignity of the profession that these charges should be met with a bold front and fought to a finish. The doctor in this case was defended by the Medical Defence Union, who have done such excellent work in protecting practitioners, and whose name is justly feared by adventurers and blackmailers.

Plasma as a Therapeutic Agent.

ANTITOXIC sera of various sorts have now so firmly taken their place in medicine that it is right that we should understand not merely the therapeutic action of the antitoxin, but that of the serum which is its vehicle. To this end Mr. Montgomerie Paton has been engaged for some years in the study of the therapeutic action of simple plasma, and he has made known his results in a recent paper (a). He has come to the conclusion that the nutritive value of plasma administered by the mouth is greater than has usually been supposed. In suckling mothers, where lactation is for any reason defective, the regular administration of plasma is found to act promptly and vigorously in producing normal secretion, and in maintaining it for the necessary length of time. Even in the case of mothers previously weakly a better condition of health is produced, and the baby's nourishment is all that can be wished. In some cases so marked was the improvement in mother and child that the mother thought it unnecessary to continue the treatment, with the result that her health again failed. In many cases of debility, particularly in the very young and the very old, after, for instance, acute infective diseases or operative interference, plasma appeared to give very beneficial results. Mr. Paton has made use of it in very varying clinical conditions—splenic leukæmia, chronic nephritis, tuberculosis, and in no case has he thought its effects unsatisfactory. His proofs are, of course, not quite conclusive, but there are no doubt many

(a) *Intercolonial Med. Jour. of Australasia*, April, 1905.

physicians willing to test the value of plasma in their own practice, so that we are likely soon to obtain fairly certain results. The plasma of the sheep is probably the easiest to obtain, and is said to have as high nutritive properties as any other.

Rectal Feeding.

IN many conditions of the stomach, such as cancer or ulcer, it is impossible to give any but the simplest foods by the natural channel, and in recent years the tendency in such cases has been to abandon oral feeding altogether in favour of feeding by the rectum. It is possible that this method has been carried too far, and it is certain that in many cases attempts have been made to administer by the rectum foods which cannot there undergo absorption. It is necessary in rectal feeding to remember the limits imposed by the disabilities of the large intestine in the matters of digestion and absorption. In the ordinary course of nature no digestion takes place in the large intestine, and it is doubtful whether this part of the alimentary canal has, in fact, any digestive powers. In the ordinary course, too, it is probable that no absorption, except of water or salts, takes place in the large intestine. There is therefore every reason to expect the easy absorption of water or saline solutions when administered by the rectum, while there is no reason to believe that foods which require digestion can be of any use when given in this way. In fact, most physicians who take the trouble of inspecting the excreta of patients undergoing rectal feeding have learnt that practically all the solids administered as food are returned unaltered, but deprived of their fluid accompaniments. Nevertheless, recent investigations by Edsall, Miller and others go to show that fats can be absorbed in fairly large amount if administered in the form of soap, and it is probable that if rectal feeding is to retain its ground in the treatment of gastric disorders, it will be in this form that foods must be administered.

American Spelling Again.

THE Editor of the *American News* in a recent issue, publishes another gibe against English medical men for their audacity in condemning the American orthography, which he so faddishly affects. What authority, however, has he for saying that this orthography displeases "a small class of English ultra-conservatives?" As a matter of fact "this small class" only consists of the whole British medical profession. Nothing is more irritating to most educated and progressive authors and editors, to quote his own words, in this country, than to have to read sentences made up of mutilated English words with which certain American authors convey their meaning. Thus an example: "Say, doc, in my opinion, the physick signs are mostly medic, and neither surgic nor gynæcic." "Cemic" for chemical is another beautiful expression arrived at by the clipping of the "al." But how "gynæcic" for gynecological

can be accounted for etymologically, surpasses our comprehension. Again, some elegant words are made in America by leaving out the unassuming hyphen, such as "medicolegal" "proofreaders," "nonobservance," all of which, and many more, are common to readers of *American Medicine*. While "sulfate," "chlorid," "sulfuric," are other instances of labour-saving words. But if "chlorid," why not "suicid" ?—that is just the point—The difficulty is to find any reason for all this clipping; still, it may be that the wages bill for the compositors are a great drain upon the finances of the medical journals published in America, and so, in the cause of economy, this clipping and chopping of English words and unnecessary mutilations may have a sound basis from an economic point of view. However, the readers of *American Medicine* are occasionally indulged with the hyphen, for on one page in a recent issue one comes across "fare-mindedness"—not quite an English word anyway, and "self-doping," whatever that may mean in America. The curious point, however, about all this medical orthographic mania in America is that the lay journals of the country never inflict such eccentricities and barbarities upon their readers. Why, then, we may ask, should the medical profession be subjected to such an irritating style of orthography?

The Scalp Isolation of School Ringworm.

One of the most practical papers read last week before the London Congress of Public Health dealt with the important subject of school ringworm. It will be found reported in another column. Its author, Dr. David Walsh, therein described a new method which bids fair to revolutionise the attitude of school, no less than of public health, authorities with regard to this widespread disease of town children. Medical men insist that no child suffering from ringworm should be allowed to attend school. But under the most skilled treatment the disease lasts from six months to two or three years, or more. To exclude ringworm children, therefore, would be to deprive a vast number of them of the greater portion of their school life. But often-times Mahomet may go to the mountain when the mountain cannot come to Mahomet. Dr. Walsh encloses the shaved scalp in a film of collodion or other impervious adhesive material. The scalp may then have a few cautious exposures to the X-rays, but this step is not indispensable. Every ten days the cap-film is gently stripped off and on its shaggy under-surface will be found a great mass of healthy and diseased hair stumps. By this wholesale depilation cure is materially hastened, but there is no fear of permanent baldness. The great feature of the discovery, however, is that while wearing the cap-film a child may be allowed to attend school, for the scalp by reason of its impervious envelope is absolutely prevented from spreading infection. In London it would be easy to start central depots under expert medical supervision, whither ring-

worm scholars could be sent every ten days or so for treatment by Dr. Walsh's method, which, so far as we can see, offers a probable solution to one of the knottiest problems of school administration.

The Ice-Cream Season.

THE ice-cream harvest is now in full swing, and swarthy Italians are waxing fat in the garnering thereof. Whatever view the man in the street may hold as to the wisdom of excluding aliens from the shores of our tight little island, there can be no two opinions as to the need of regulating these trade operations if carried on to the danger of the health of the community. Yet ice-cream vendors too often spread disease and death far and wide in the course of their unwholesome traffic. Again and again it has been shown that the milk, the flour, the water, the ice, and other ingredients of their pestiferous dainties are kept in filthy garrets and courts and under conditions that are simply revolting to every sense of sanitary cleanliness. The vessels in which the ices are made are unclean beyond belief. What wonder if under these circumstances their ices contain germs of typhoid fever, diphtheria, bowel organisms, and many other disease-producing bacteria in hosts. Last but not least they are as a rule sold to children in small glasses from which they are actually lapped up by the unhappy little customers. In Birmingham recently two hundred children were poisoned by the polluted products of a single "hokey pokey" barrow. It is high time that local authorities imposed stringent regulations everywhere to control this most undesirable species of alien enterprise. Medical science has revealed the danger, lock, stock and barrel. It now remains for the civic authorities to act on the information and look to their by-laws.

Cigars and Bribery.

THE medical profession, sooth to say, is exploited on all hands by what the stockbrokers would call "bucket-shop" keepers. Out of our medical charities many fortunes are made by contracts of drugs, meat, groceries, milk and what not; lawyers make huge sums by managing mortgages, conveyances, and so on of property that in almost incredible bulk belongs to richly-endowed hospitals like St. Bartholomew's and Guy's; nursing journal editors make enormously valuable properties by exploiting the hospitals and obtaining their advertisements at high rates; society folk and City men get huge slices of patronage and angle, not unsuccessfully, for social prominence and titles. It is medical men generally who, so far from getting anything out of the medical charities, find in those institutions their keenest rivals, eager to rob them of their poorer patients by the pernicious pay system that permits Guy's Hospital and the London to take the pence of the poor with unblushing face, although the public pour hundreds of thousands of pounds into their coffers for the relief of the poor. Among

the unceasing exploitations comes a peculiarly degrading one in the shape of an enterprising cigar merchant who offers all medical men a reduction of 30 per cent, on his particular brand of cigars if the purchasers will recommend their wares to their patients. Knowing the ways of commerce, it is fairly self-evident that the merchant will lose nothing out of pocket in sacrificing 30 per cent. from retail prices. *Truth*, ever ready to take up the cudgels on behalf of the medical profession, has fearlessly and continuously exposed artifices of this kind, and naturally advises patients to beware of advice as to cigars coming from their medical men. We trust for the honour of our profession that no such meretricious advice will be forthcoming.

PERSONAL.

UNDER the auspices of their Majesties the King and Queen, it was recently decided that a new Red Cross Society be formed to co-ordinate all those existing societies concerned with the succour of the sick and wounded in war. A Council has been appointed by their Majesties, under the presidency of the Queen, with Lord Rothschild as chairman, and Lord Knutsford, Lord Esher, Lord Cheylesmore, and Mr. A. Loyd, M.P., as vice-chairmen.

H.R.H. PRINCESS CHRISTIAN, who was accompanied by her Highness Princess Victoria of Schleswig-Holstein, on the 17th inst. presided over a meeting of the Executive Committee of the National Committee for the Establishment of Sanatoria for Workers Suffering from Tuberculosis.

OWING to an epidemic of rabies in Penang, which has already resulted in four deaths, it is announced that Leong Fee, the Chinese Consul, has offered the Government to build and equip a Pasteur institute for the Straits Settlements and the neighbouring regions.

DR. CHARLES O'REILLY, of Toronto, is the Canadian delegate to the British Medical Association meeting this week at Leicester.

ON the 16th inst., the Duchess of Westminster opened the new maternity wards at the London Hospital.

THE French Ambassador, M. Cambon, recently unveiled at the French Hospital, Shaftesbury Avenue, a statue of the late Dr. Achille Vintras, its founder. The statue, which is the work of M. Lenteri, is in bronze and bears an inscription in French to the following effect: "To Doctor Achille Vintras, Founder and Physician-in-Chief of the French Hospital in London, from the grateful French Colony."

At a meeting of the Court of Edinburgh University on July 17th, the resignation was intimated and accepted of Professor Alexander Russell Simpson, who has filled the Chair of Midwifery for thirty-five years.

MR. ERNEST POWELL KING, of Wainsford, near Lymington, whose will has now been proved, left £100 each to the London Temperance Hospital, the National Hospital for the Paralysed and Epileptic, Queen Square, and the Royal South Hants Infirmary.

DR. HOWARD A. KELLY, of Johns Hopkins Hospital, Baltimore, was among those who received the Hon. Fellowship of the R.C.S.Ed., on the occasion of the Quatercentenary.

SIR RICHARD DOUGLAS POWELL, M.D., President of the Royal College of Physicians of London, has been

unanimously elected an honorary Fellow of the Royal College of Physicians of Ireland.

DR. C. H. C. FARQUHARSON has been appointed District Medical Officer at Port Maria, Jamaica, in place of Dr. J. A. L. Calder, transferred to Santa Cruz.

DR. F. A. BALDWIN has been appointed Medical Officer of the Gambia, West Africa.

DR. D. J. WILLIAMS, Medical Superintendent of the Lunatic Asylum, Jamaica, has arrived in England on leave of absence.

THE French Académie de Médecine has awarded, through the Minister of the Interior, a silver medal to Dr. Alan B. Green, bacteriologist in charge of the vaccine lymph department of the Lister Institute of Preventive Medicine, for his work on "Vaccine."

PROFESSOR D. I. MENDELEEFF, the distinguished professor of chemistry at St. Petersburg University, completed the fiftieth year of his public professional services on June 13th. A celebration in recognition of his services will take place on August 30th.

British Medical Association.

SEVENTY-THIRD ANNUAL MEETING, JULY 24TH TO 28TH
[NOTES FROM OUR SPECIAL CORRESPONDENT.]

ALTHOUGH Leicester cannot offer the classic attractions of last year's meeting-place it is a prominent centre of activity and offers manifestations of progress which make it a welcome gathering ground for the representatives of British Medicine. Great efforts and elaborate preparations have been made to ensure a successful meeting. Both the profession and the public have done their best to provide hospitality, social delights, and sound scientific food for the numerous visitors who have come from all parts of the country to meet friends and discuss the many problems which cluster about the science and art of medicine.

Leicester is an excellent railway centre, and the great facilities for attractive travelling are bringing many visitors to this year's gathering. Whatever may be said of the permanent scientific value of the "Annual Picnic" it is generally admitted that it offers a most desirable opportunity for the renewal of old friendships and the making of fresh friends.

THE NEW PRESIDENT.

Mr. George Cooper Franklin, the new President, is a thorough representative of Leicester. Born in the borough in 1846 he has practised within its borders for 30 years, winning honour as a citizen and gaining respect as a trusted surgeon and medical adviser. He received his general education at Leatherhead, in Surrey, and at Stonegate School, and his professional training at St. Thomas' Hospital in London. Mr. Franklin took his M.R.C.S. in 1870 and was admitted L.R.C.P. in 1871. In 1873 he was received after examination as F.R.C.S. Settling in his native town in 1875 he was soon appointed surgeon to the Leicester Provident Dispensary. In 1886 he joined the staff of the Leicester Infirmary; and now, after nearly twenty years of service, is senior surgeon. Although pre-eminently a surgeon, Mr. Franklin may be well characterised as an all-round practitioner, and it is interesting to note that from 1871-74 he was Resident Medical Officer to the City of London Hospital for Diseases of the Chest. Mr. Franklin, although by no means a voluminous writer, has contributed some valuable papers to scientific

medicine. In 1875 in collaboration with the late Dr. W. E. Buck, he issued a "Report on the Epidemic Diarrhoea of Leicester." He has also written on "Intra-thoracic Disease," and "Criminal Abortion."

The President has also played a prominent part as a citizen of Leicester; and as member of the Town Council, Churchwarden, and supporter of many societies—professional, benevolent, and social—he has exercised widespread influence. In this instance at least a practitioner of medicine has won honour in his own country, and to-day he has the proud distinction of presiding over the largest and most representative association of medical men in this country.

THE WORK OF THE SECTIONS.

Although the programme of the scientific work of the sections does not promise any startling features, and in some respects is disappointing, there is evidence that the discussions which have been arranged for will be of service in reviewing and perhaps extending knowledge and improving our practical methods. It is much to be regretted that under the new regime the purely business matters of the Association monopolise an immense amount of the time of many, and some who might well be taking a valuable part in the scientific work of the sections are held captive in the meetings of the Council. A growing number of members make entertainments and excursions their main interest. Thus it happens that between business and pleasure scientific medicine is in danger of being neglected. The foolish and short-sighted policy of the powers that be in issuing the notice that "Papers read are the property of the British Medical Association and cannot be published elsewhere than in the *British Medical Journal* without special permission" has also done much to discourage the best workers from taking part in the proceedings. There are twelve sections,

which meet on the mornings of Wednesday, Thursday, and Friday, July 26th, 27th, and 28th.

THE DISCUSSIONS.

Modern opinion and present-day practice clearly indicate that papers are of much less interest and service than suitably arranged and well directed discussions. The former can be printed and quietly considered as they appear in the pages of the *Journal*, but a discussion has wide educational value and does much to focus attention and energise effort along reliable paths. The discussions which have been arranged for promise to be of distinct interest, and no doubt will attract much notice. Sir Lauder Brunton is to open the discussion on the treatment of sleeplessness and pain; Dr. Howard Tooth speaks on the various forms of acute meningitis; Dr. Julius Dreschfeld deals with the diagnosis and treatment of cardiac degeneration. In the surgical section Mr. Moynihan will open the discussion on the surgical treatment of non-malignant diseases of the stomach; and Sir Charles Ball that on the treatment of malignant disease of the rectum. It seems likely that the section of state medicine will prove one of the most attractive departments, for here discussions have been arranged for on such much debated questions as—hospital isolation for infectious disease, sanatoria for the consumptive poor, infant milk depots, and, "What is notifiable diphtheria?"

In such a commercial centre as Leicester there should be much prominence given to industrial hygiene and diseases of occupation, and in the section devoted to these there are to be discussions on physical deterioration, anthrax, and accident and poisoning reports. The other more special sections offer attractive bills of fare which no doubt will provide select audiences of enthusiasts.

An attractive *Guide to Leicester and Neighbourhood* has been prepared by Mrs. G. Clarke Nuttall, B.Sc., and will prove invaluable as a concise and reliable handbook for visitors. The author, we understand, is the wife of a local medical man, and Dr. Reginald Pratt and others have assisted in its preparation.

The Temperance Breakfast organised by the Chairman and Committee of the National Temperance League has become a popular institution in connection with the Annual Gathering of the Medical Association, and this year the Dean of Hereford is to preside. The breakfast is held on Thursday, July 27th, at 8 a.m., in the Leicester Temperance Hall.

A number of Leicester factories will be open for inspection and should attract many who desire to observe for themselves conditions of industrial life and work.

The Pathological Museum is housed in a large room of the first floor of the technical schools and contains a valuable collection of gynaecological specimens and other preparations of pathological interest.

Receptions, garden parties, excursions, golf, and other delights have been arranged for, and in all probability will prove the most enjoyable and best patronised features of the Leicester Annual Meeting.

The Annual General Meeting of the Association was held in the Association Hall of the Leicester Y.M.C.A. on Monday afternoon. On Tuesday (July 25th) morning the new Council met and representative meetings were held. The customary religious services were conducted in the afternoon. Last night the President delivered

his address, and there was the usual reception of distinguished guests. To-day (Wednesday, July 26th) the real work of the meeting begins.

Special Articles.

THE LONDON CONGRESS OF PUBLIC HEALTH.

THE Annual Congress of the Royal Institute of Public Health has been held this year for the first time in London. It was largely attended and its organisation having been carried on on a comprehensive basis, the result must be of a most satisfactory nature to those concerned in the meeting. Proceedings began on Wednesday, July 19th, with an inaugural address by the Marquis of Londonderry, who at the same time opened a highly interesting exhibition at His Majesty's Theatre. Professor W. R. Smith was in the Chair, and formally welcomed the delegates and visitors to the Congress. Lord Londonderry delivered an interesting address on physical efficiency, and insisted on the need of educating the public in health matters. On the 20th, the Congress dinner was held at the Hotel Cecil, and was followed by a dance. Numerous excursions were organised to various places of interest, such as Taplow Court, Windsor, Burroughs Wellcome's manufactory at Dartford, the Downs Ringworm Schools, Hatfield, and a score of other places. On Sunday special services were held at St. Paul's and the Roman Catholic Cathedrals, as well as at the City Temple, Southwark Cathedral, and other churches and chapels. Scientific work began again on the 24th and 25th, and the Congress closed at the end of the latter day. As regards the sectional work, a number of first-rate papers were read in the various sections, which included Preventive Medicine, Municipal Administration of the Education Acts, Child Study and School Hygiene, Engineering, Bacteriology and Chemistry, Veterinary Hygiene, Practical Hygiene, Naval and Military Hygiene. The Section of Preventive Medicine was opened by that brilliant Nestor of Medicine, Sir J. Crichton Browne, who gave a characteristic address showing how the ideal average of life might be placed at a century. There were quite a number of papers by first-rate men dealing with sewage problems, especially in relation to river purification and sewage discharge. By some mischance, a bold suggestion advanced by Dr. Walsh that all sewage effluents should be sterilised by heat before discharge into streams, drifted into the Bacteriological Section. The last-mentioned section had some excellent discussions, one of them dealing with the possibility of establishing a bacteriological standard of purity for milk, opened by Professor MacFadyen, and maintained by Professor Kenwood, Nathan Raw, Dr. W. G. Savage, and others. Great interest and activity was manifest in the Veterinary Section, and some excellent papers were contributed dealing with meat and milk problems. In the Tropical Hygiene Section, one of the best contributions was on tropical life insurance by Mr. James Cautlee. In no section was better work done than in that devoted to Child Study and School Hygiene. Dr. George Carpenter, one of the Hon. Secretaries, read a valuable paper on the present high infantile mortality rate. Another important contribution was that of Postural Defects in Children, by Mr. Alfred Tubby. Among many other valuable papers was one by Dr. David Walsh urging the isolation of individual scalps in children, who might then be sent safely to school. This principle appears not unlikely to revolutionise school ringworm. The Child's Section was presided over by Lord Stanley, who delivered the kind of wise philosophical address one would expect from an educationalist of his great experience and culture. Altogether the Institute of Public Health may be congratulated on having achieved a most brilliant and successful Congress.

Correspondence.

IN DEFENCE OF THE PESSARY.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Having read with interest the valuable paper by Dr. Granville Bantock on the above subject in your last issue, I venture to notice a few points. Having myself been able to give more relief to females suffering from various symptoms due to displacements of the uterus, by means of replacement and a properly adjusted pessary, I naturally agree with much Dr. Bantock states (though I fancy it is some time since the paper was written, no date being given). I have always maintained that *true displacement of any form does not exist with a healthy uterus*, and the frequent existence of abnormal secretion alone would show this. I can quite understand the advocates of operation as a cure? for displacement, upholding their views, when such a man as Marion Sims can state "It has frequently taken me a fortnight and sometimes much longer, to adjust an instrument accurately, and sometimes it has been utterly impossible for me to do it at all." (page 280). Is it any wonder then, gynaecologists of the present day, finding themselves in a similar position (instead of recommending a brother practitioner, who understands the value of pessaries, and who might succeed, and save the patient expense, pain and risk), at once resort to operation? (It might be considered unkind should I suggest that an operation would pay better, and we all know it is easier to cut a cord than to untie a knot.) Call it "suspension" or "fixation," is it common sense to tether an organ (meant to have free movement) for all lifetime, when the same result can be almost all cases be attained by care, skill, and a well-adjusted pessary? I quite agree with Dr. Bantock in his wholesale condemnation of ring pessaries (above all, the rubber form). As I pointed out myself years ago, the vulcanite pessary can be softened in boiling water, moulded to the shape required, and then dipped into cold water, when it will retain its shape. The advantage of the block-tin instrument over it being: *It can be bent by the fingers after introduction* and retains its shape, and I have thus succeeded where the vulcanite instrument has failed.

I have found it a good plan, when the patient is fitted with pessary in consulting room, to ask her to drop down in sitting posture on a hard chair. If any complaint is made, the pessary does not fit and should be readjusted.

Should the percentage of failures by the suspension or fixation treatment of flexions, &c., increase, I presume the next step will be alteration of the female pelvis.

I am, Sir, yours truly,

July 20th, 1905.

ALEXANDER DUKE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I agree with the greater part of Dr. Bantock's very able paper on the above subject in your issue of the 19th inst., and, referring to his last paragraph, I do not consider he has used expressions one whit too strong, having regard to the importance of the subject and the ignorance often displayed in the treatment of displacements and flexions of the uterus. I would like with your permission to make a few remarks on the paper in passing.

I think in the first place, since gynaecology has drifted so much lately into the domain of surgery, that practitioners do not exercise the sufficient patience that the proper treatment of such cases entails, and so they betake themselves to the route that holds out a prospect of cure in the shortest possible time. Dr. Bantock remarks: "No work with which I am acquainted, with the exception of that of Hart and Barbour, clearly observes this distinction"—that between *retroversion* and *retroflexion*. I wish to draw attention to the fact that in my book, "Practical Gynaecology," I make the distinction very plain, giving separate sections to each condition. With regard to anteversion, the condition of the foetal uterus is that of antecurve, the cervix being as long as the body.

One word with regard to the Albert Smith-Hodge pessary. I devised and used at the Hospital for Women, the double curve, rendering the Hodge more effective in maintaining a retroverted uterus in its normal position, before I was aware that Albert Smith had suggested the same improvements, so that the present form may be acknowledged as a *Double Smith-Hodge pessary*.

I do not agree with Dr. Bantock that "retroversion with anteflexion is so very rare." I have not unfrequently found an anteflexion with the os uteri pointing towards the pubes, so that the lower portion is in a position of retroversion while the fundus is anteflexed. I quite agree with Dr. Bantock that to insert a pessary without first replacing the uterus, in the hope that it will restore the uterus to its normal position, shows lamentable ignorance, as also it does to put it in upside down!

Dr. Bantock rightly advocates the use of the sound for the replacement, and if the operator has a light hand, or if, finding the uterus tender, he first of all reduces the inflammatory condition, no harm will ensue. His directions as to the way the sound is to be used for the replacement leaves nothing to be desired. Dr. Bantock is rather hard on the "ring" pessary. I have found it of great service in some cases of early proclitidia, and also in prolapse of the vaginal walls, but he is quite right when he says that "it is impossible for a ring pessary to cure a simple case of retroversion."

These vaginal pessaries are absolutely useless to restore cases of anteflexion; nothing will do but some form of intra-uterine stem. In many cases where the os uteri is very small and the canal narrow, merely to dilate the canal with graduated sounds is only of temporary service; the uterus soon returns to its former condition. I have found the best plan is to dilate, then make two slight incisions inside the canal, forcibly dilate with Marion Sims' "glove-stretcher," which slightly tears the cervical fibres, and then insert a glass stem for a few days, when the dilatation will remain permanent, and pregnancy, often impossible before, will supervene.

I quite agree with Dr. Bantock that when a retroversion is complicated with adhesions, it is quite possible after appropriate treatment to be able gradually to restore the uterus to its normal position.

With regard to the best material for pessaries, I unhesitatingly give the preference to the plastic celluloid, *i.e.*, soft celluloid with a wire core; and when the proper size and shape have been ascertained, and the patient is able to wear it quite comfortably, *i.e.*, almost without being aware of its presence, a hollow aluminium one should be made to the exact pattern, and this by its lightness and cleanliness will greatly conduce to the patient's comfort.

I am, Sir, yours truly,
HEYWOOD SMITH.

Welbeck Street, London, July 22nd, 1905.

THE CANCER PROBLEM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I was privileged forty years ago to attend the wards of the Middlesex Hospital, and was much impressed with the masculine type of the women who suffered from cancer. The incidence of cancer is mostly after the cessation of the great and widely correlated—nay, cosmic—phenomena of maternity. It is then that the "energies" which have, up to 40 or 50 years of age, made for the greatest of all the processes and purposes of life, take in a different direction, and there often results the exuberance of cell development known as cancer.

Histologically, it is not possible to conceive that the cosmic energies which produce the sexual system, and the capacity for maternity, stop abruptly with the cessation of the monthly and ovarian functions; a *reliquia*, in biological continuity, must survive, and which seem to find their expression in the cell development of different layers of the blastoderm, especially

of the epiblast and its differentiations. In walks through the country, one may see "wild"—*i.e.*, naturally situated and treated—plants, run to a great exuberance of growth after the period of their flowering and fructification. Is the exuberance of cancer-cell growth parallel with such phenomena in plants?

I would venture to suggest the administration of ovarian tissue and its "modes" to a series of cancer cases, in women who have passed the age of child-bearing; the idea being, that, by even a most partial restoration to the system of its former "modes" and corelations, we might alter the metabolism and divert the "energies" which determine the epithelial cancer-cell evolution back into their old channels of harmonious corelation and continuity. Many analogies point to such a general method. Biology is full of instances of the intimate and essential corelations of the functions and structures of the system. We may not hope at present to compass the law and ratio of the organic evolution, to do in biology what Kepler did in celestial motions, or Grove did in the "corelation and continuity of the physical energies," but we may fairly hope for increasing light on biological corelations and continuity, attained by observation and analogy.

Darwin has given us a vast series of illustrations of how small changes of inner and outer environment determine the greatest variation in plants and animals, from the paleoneological series down to our present fauna. Observation of Nature and analogy may lead us to discovery long before we have unfolded the chemical or cellular continuity.

I venture to make the suggestion of the administration to women of ovarian cell modes and "motions"; and to men at the ages of decay of the sexual powers, of testicular modes and energies.

If it fail, others may be led to see and think more clearly and accurately.

I am, Sir, yours truly,
WILLIAM H. PEARSE.

Plymouth, July 20th, 1905.

Obituary.

JOHN JAMES RUTHERFORD, M.D.St.AND.,
F.R.C.P.Ed.

It is with regret that we record the death of Dr John James Rutherford, of Shipley, which took place at his residence on the 16th inst. Dr. Rutherford, who was one of the best known men in the Shipley district, had been failing in health for a considerable period, and it had been known for some time that there was little, if any, hope of his recovery. So long ago as in 1900, Dr. Rutherford had the misfortune to contract blood-poisoning during an operation, and he was then for some time seriously ill. Born at Kirkmichael, in Dumfriesshire, in 1846, Dr. Rutherford was in his fifty-ninth year. He was, of course, one of the oldest medical practitioners in the town, and his practice extended for a long time over a wide area. For six years Dr. Rutherford occupied the position of Medical Officer of Health for the Shipley district.

ELLERY TURNER, M.R.C.S.ENG.

We regret to record the death of Mr. Ellery Turner, formerly practising at Beverley, Yorks, who was found dead in bed at Rowton House, Vauxhall, where he had resided for four years. Mr. Turner graduated M.R.C.S.Eng. in 1865, and was highly esteemed by his patients and friends. He had been in failing health for the past six months.

JAMES MUDGE, M.R.C.S.ENG., L.R.C.P.ED., L.S.A.

The sudden death of Dr. J. Mudge, in Marazion, last week, has caused great regret in the neighbourhood. Deceased was well known, and, being of a genial disposition, his company was much sought after by a large circle of friends. He was medical officer of

health, public vaccinator, and medical officer to the eastern portion of Penzance Union. He graduated L.R.C.P.Ed. and M.R.C.S.Eng. in 1879, and commenced practice at Marazion about twenty-five years ago, where he had a large private practice, and was considered very skilful in his profession. Deceased, who was a native of Hayle, where he has two brothers in practice, was 47 years of age. Great sympathy is felt for the widow and three children.

DANIEL MURPHY, M.B., B.Ch., B.A.O., R.U.I.

THE loss of a genial and much esteemed young doctor of Cork, Mr. Daniel Murphy, has caused sincere regret in that city. He had been in ill health for some time, and spent the winter in Nordrach, where at first he seemed to make some progress towards recovery, but later he found it necessary to return home, where he died after a few days. For several years after graduation in 1893, Dr. Murphy was house-surgeon to the North Cork Fever Hospital, and afterwards became house-surgeon to the North Charitable Infirmary, Cork, for a few years, but on a vacancy occurring in one of the dispensaries of the city he was elected to, and until his death held the post.

WILLIAM DUNCAN, L.F.P.S. GLASG.

WE regret to record the death of Mr. William Duncan who for the past fourteen years has been in practice in Belfast, and died on July 11th after a lingering pulmonary illness. He was only 46 years of age and owing to his skill, genial disposition, and sympathetic nature he enjoyed a large practice among the working classes of Belfast. He leaves a widow and family.

Literature.

ABDOMINAL PAIN. (a)

WE confess to rising from the perusal of Mr. Ernest Maylard's "Abdominal Pain," with a sigh of disappointment. When we took it up, recollections of Hilton, the wise, the suggestive, the inspiring, and of Head, the brilliant, the original, the accurate, made us anticipate a treatise of philosophical breadth and ripe thought. Instead, we find a scrappy, disjointed set of facts, which strike us as having been put together without much reflection. There is little about abdominal pain that is new; and what is old is trite. The author starts out with the intention of helping the proverbial busy doctor in the differential diagnosis of obscure abdominal disease, but his method of procedure—namely, giving tables of the causes of pain occurring at various points, and some hasty remarks on the pains in other parts of the book, will not, we fear, be of much assistance to the bulk of practitioners. Mr. Maylard never comes to close quarters with his subject; he is for ever skirting round it; every now and again he looks as though he means business, but when it comes to the point he evaporates into banalities. Lack of space is a frequent reason given for not dealing thoroughly with a topic, but this reason looks uncommonly like an excuse in face of the fact that the last third of the book is taken up, not with abdominal pain at all, but with directions and hints on the technique of laparotomy. It is difficult to see why these chapters were introduced at all. They have a value as the embodiment of the ideas of a practical operator, but they cannot be said to be apposite. We note with pleasure that Mr. Maylard has the courage to record a case of pneumonia in which he was led to open the abdomen under the impression that the trouble was situated below the diaphragm; the mistake is not infrequently made in these days of early operation, but most of the surgeons and physicians concerned prefer to record other evidences of their perspicacity. Another point on which Dr. Maylard's experience is useful is in the definite citation of a case in which a calculus in one

kidney caused pain in the opposite loin; this possibility has been denied, but Mr. Maylard's case furnishes demonstrative evidence. Those who do not possess diagrams of Head's areas will be glad to find excellent plates reproduced in this volume, and, indeed, the whole printing and get-up of the book are uniformly creditable. We wish we could say the same of the literary style. Infinitives are split in ruthless fashion, and many sentences show marked lack of skill. Thus, page 36, "Such a consideration also tends to bridge the gap or unite together, what, on one side may be regarded," &c., and again, page 45, "Thus any portion of the alimentary tract, when incapable from stricture or other obstructing cause of normally passing on the contents of one section of the canal into another, begins to distend on the proximal side; and by exciting renewed and increasingly more vigorous efforts at muscular contraction, causes pain." To students who are making their first acquaintance with the mysteries of abdominal disease this book may be acceptable.

HERSCHELL ON ELECTRICAL METHODS FOR STOMACH. (a)

THIS little work sets forth the author's experience in a domain which he has made especially his own. Recent electrical developments have greatly increased the therapeutic power of applied electrical currents. It is hard to imagine any more brilliant achievement in practical medicine than the cures obtained in dilatation of the stomach. Those who wish to find an eminently clear account of the methods to be adopted in the electrical treatment of various affections will do well to consult this excellent little volume. Clearly if the theories as to the causation of functional gastric disorder hold good, it should be capable of receiving benefit from electrical treatment. The chapter on gastric neurasthenia or nervous indigestion connotes a catholic education, so to speak, in all branches of medical knowledge. The general practitioner will do well to make himself acquainted with the role of modern electrical therapeutics in constipation due to intestinal atony, and in other atonic, neurasthenic, and myasthenic disorders of digestion. Dr. Herschell has made a modest but sound addition to the understandig of a progressive subject.

Medical News.

Society for Relief of Widows and Orphans of Medical Men.

AT the 'Quarterly Court of Directors, held on Wednesday, Mr. Christopher Heath, President, in the chair, the Secretary reported that one death and one resignation had occurred among the members since the last meeting. The death of a widow was mentioned who had been an annuitant of the Society since 1886, and had received in grants the sum of £1,063 5s.; her husband had paid £52 10s. in subscriptions. An application for relief had been received from a widow of a deceased member, and a grant at the rate of £50 per annum was voted. Fifty-three widows and thirty-six orphans are now in receipt of relief, the total sum for the half-yearly grants being £1,324. Three new members were elected. The Secretary reported that during the past three months, fifteen letters had been received from widows of medical men, soliciting grants, and relief had to be refused in every case, owing to the fact that their late husbands had not been members of the Society. The annual election of the Secretary took place, and Mr. Edward J. Blackett was appointed to the post.

Deaths From Plague in India.

DURING the weeks ending June 17th and 24th, the deaths from plague in India numbered respectively 4,883 and 4,563. The principal figures were: Bombay City, 151 and 135; Bombay Districts, 238 and 255;

(a) "Abdominal Pain: Its Causes and Clinical Significance." By A. Ernest Maylard, M.B., B.S.Lond., Surgeon to the Victoria Infirmary, Glasgow, &c. London: J. and A. Churchill. 1905. 7s. 6d net.

(a). "Electrical Methods in the Treatment of Affections of the Stomach and Intestines." By George Herschell, M.D.Lond., Physician, Welbeck Street Hospital for Nervous Diseases, &c. London: A. Siegle, 1905.

Calcutta, 52 and 37; Bengal Districts, 289 and 162; North-West Provinces and Oudh, 396 and 151; Punjab 3,389 and 3,663; Rajputana, 285 and 82; Kashmir, 3 and 11; Mysore, 23 and 23; Madras Districts, 6 and 3; Burma, 82 and 93. From the shores of the Persian Gulf and Bahrein Island deaths from plague are also reported.

Cancer Death Rate.

ACCORDING to the report of Dr. James B. Wilkinson, which was laid before the Huntingdonshire County Council, this particular county has, if not actually the highest death-rate from cancer of any county in England, a rate which closely approximates to it.

The Medical Act 1886 Amendment Bill

was read for the third time last week. The Bill is intended to carry out the principle of reciprocity between the mother country and Canada in the matter of medical education. During the war in South Africa a number of medical men volunteered to serve with the Army, but the War Office said it was contrary to our law for them to attend a British soldier or to hold a British appointment. This Bill would enable these doctors to enter the service of this country as if they had been born here.

Grave Charge against a Medical Man.

THE Director of Public Prosecutions has intimated that he will take up the prosecution of Dr. Brooks and Arthur Stanton Price, chemist, of Cardiff, who are committed for trial at the assizes at Swansea next week on a charge of attempting to procure abortion.

PASS LISTS.

University of Aberdeen.

At the Graduation ceremonial last week, the following candidates, having passed the necessary examinations, received the Degree of Doctor of Medicine (M.D.) William Johnston Dewar, M.B., C.M., Francis Grice Jones, M.B., C.M. (Commendation for Thesis), George Grant Macdonald, M.A., M.B., Ch.B. (Honours for Thesis), J. Thornton Macpherson, M.B., C.M., John S. Milne, M.A., M.B., Ch.B. (Highest Honours for Thesis), George Mitchell, M.B., Ch.B. (Honours for Thesis), Herbert Leith Murray, M.B., Ch.B. (Commendation for Thesis), Alex. Charles Profeit, M.B., C.M., Alex. Christie Reid, M.A., M.B., Ch.B., B.Sc.

Degree of Master of Surgery (Ch.M.), John Alex. Mackenzie, M.A., M.B., Ch.B. (Honours for Thesis).

Pass List for Degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.), (New Ordinances).—James M. Adams, M.A., William Campbell, Alexander Donaldson, Robert R. Duncan, Richard Eager, Francis W. Falconer, William M. Fergusson, George J. Forgie, Reginald A. Forster, George Hall, M.A., Alexander W. Laing, James McIntosh, James Mackenzie, Kenneth Mackinnon, George Milne, John A. Milne, Harry R. Neilson, Paul B. Roth, Robert F. Russell, James Silver, F.C., Charles M. Smith, John H. Stephen, I. F. Bernhardt de Villiers, Frederick H. Welsh, Cristina Wilson, Douglas Wood.

NOTE.—Charles Butchart Gerrard has passed all the examinations, but will not graduate until he has attained the necessary age.

The John Murray Medal and Scholarship was awarded to Robert Brown, M.B., Ch.B., Aberdeen.

Diploma in Public Health.—Donald J. G. Johnston, M.B., Ch.B. Aberd., Alexander McRobbie, M.B., Ch.B. Aberd., George A. Ma vor, M.A., M.B., Ch.B. Aberd.

Royal College of Surgeons in Ireland.

FELLOWSHIP EXAMINATION.—The following candidates having passed the necessary examination, have been admitted Fellows of the College:—Mr. J. Campbell, L.R.C.P. & S. I. and Mr. W. J. Mullin, M.B., B.Ch., New Zealand.

Conjoint Examinations in Ireland.

THE following candidates have passed the third professional examination as undernoted.—R. Adams, C. Anderson, Miss H. Beamish, R. M. Bronte, W. Carroll, M. E. Cussen, F. Coates, W. J. Deighan, R. Galway, J. Grace, F. M. Hewson, P. M. Keane, G. H. Kinmouth,

E. Montgomery, P. Mullany, P. J. McKeveit, D. O'Flynn, J. P. O'Kane, H. J. Perry, J. T. Reardon, W. C. T. Robert, and C. Sheehan.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Faculty of Physicians and Surgeons of Glasgow.

THE quarterly examinations of the above Board, held in Edinburgh, were concluded on the 18th instant, with the following results:—

First Examination, 4 years' Course.—James Edmund Syme passed this examination.

First Examination, 5 Years' Course.—Of 32 candidates entered, the following 13 passed the examination: F. C. Eberhardt, R. W. A. Brown, S. B. Mehta, Beatrice Coxon, Dora Robbins, K. S. Commissariatwalla, C. J. Lacayo, B. S. Tarapurwalla, J. Paxton, R. F. Lunn, J. Morham, and R. R. Bakshi. Five others passed in Physics, seven in Biology, and two in Chemistry.

Second Examination, 5 Years' Course.—Of 43 candidates entered, the following 24 passed: G. H. Urquhart, K. S. Commissariatwalla, M. B. Patel, C. Berry, A. E. James, N. Walshe-Davidson, E. Eccles, J. H. Bennett, R. E. Laurent, R. G. Sherlock, Effie J. Cassels, H. G. Ramsbottom, O. Carlyle, R. B. M. Sullivan, C. C. Campbell, Maria S. Allen, E. S. Shach, A. Johnstone Brown (with distinction), Marguerite A. C. Douglas J. B. Kelso, E. Gibson, W. R. Waddell, C. A. O'Driscoll, and T. B. Johnstone. Two others passed in Anatomy, and three in Physiology.

Third Examination, 5 Years' Course.—Of 29 candidates entered, the following 20 passed: S. I. Hasan H. C. Orrin, J. H. Simpson, H. J. Corrie, Ada C. Boylette, H. F. Shepherd, R. K. Nisbet, T. D. Murison, H. D. Stewart, A. Rae, G. E. Anderson, G. E. Nash, A. M. Davie, H. H. Babington, J. S. Ward, Ethel A. Orchard, Nathaniel Moxon, R. F. C. H. Buchanan, Charlotte E. Pring, and Constance Colley. One other passed in Pathology.

Final Examination.—Of 51 candidates entered, the following 24 passed, and were admitted L.R.C.P.E., L.R.C.S.E., and L.F.P.S.G.:—R. M. Fraser, Edinburgh; Mary C. Hamilton, London; G. A. S. Hamilton, Dublin, L. L. Carlos, Cochin, India; R. Wearing, Accrington; A. F. Demary, Canada; Tom N. Darling, Reading; H. A. Bray, Canada; J. N. G. W. McMorris, St. John's, N.F.; J. W. Pell, London; J. K. Lindsay, Edinburgh; E. P. Haythornthwaite, Cumberland; A. L. Pereira, Colombo; G. W. Barber, Ontario; J. W. Wigham, Toronto; C. Chaves, India; E. F. Nyhan, co. Cork; A. S. Donaldson, Canada; Albert E. Tanner, Calicut; P. De Mello, Bombay; J. J. Matheson, Ontario; J. S. Farries, Dumfriesshire; J. R. Purcell, co. Meath; and J. W. Skelley, Govan; and three passed in Medicine and Therapeutics, four in Midwifery, and six in Medical Jurisprudence.

Society of Apothecaries of London.

THE following candidates, having passed the necessary examinations, have been granted the L.S.A. diploma of the Society, entitling them to practice medicine, surgery, and midwifery:—V. H. Blake, A. M. Paterson, C. A. K. Renshaw, L. W. Roberts, L. Sells.

THE first congress of the International Society of Surgery will be held in Brussels in September, under the patronage of His Majesty the King of the Belgians.

THE first International Congress of Physical Therapy will be held at Liège from August 12th to 15th, under the patronage of the Belgian Government.

THE Western Hospital for Diseases of the Skin has been awarded a grant by the Committee of the Metropolitan Hospital Sunday Fund.

THE Accidents (Mines and Factories) Bill, a Government Bill, which affected prejudicially the position of Factory Surgeons, was withdrawn last week.

AN examination for the Radcliffe Travelling Fellowship, of the annual value of £200, tenable for three years, will be held in Hilary Term, 1906, at Oxford.

Notices to Correspondents, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

MARINA.—There is no doubt that the ill-regulated haphazard sea-bathing is responsible for a great deal of harm, and we agree that more ought to be known by the laity of conditions in which it may do actual harm. One of the most fruitful cases of fatal accidents is attempting to swim in a rough sea or for a long distance without the practice required to get into proper bodily training.

DR. F. (Bedford). We do not quite agree with you. In spite of the particularly fatal combination of phthisis and insanity, the results, under open air treatment, have been encouraging, judging from asylum reports. The insanity is probably of toxic origin.

COUNTRY DOCTOR.—(1) The only consolation is that if they live long enough, people who doctor themselves become our best patients. (2) Certainly, the physician who prescribes has a right to prosecute any druggist not faithfully dispensing what he orders.

EPIDEMIC.—A few years ago New York seldom had a case of cerebro-spinal meningitis notified. In 1903 there were 271, and in 1904 1,211.

DR. H. (Abergeldy).—Betul-ol, often used for friction in rheumatism is a mentholic acid combined with the methyl ester of the salicylic radicle. The tree is the *betula lenta*.

E. H. (Croydon).—Statistics show a great diminution in medical students in the U.S. during the past 20 years, but the professors deem this a matter of congratulation, tending to the weeding out of incompetents.

THERMAL DOCTOR.—In many waters which have an indeterminate composition and are well marked for their curative properties, radio-activity has been especially well marked.

DR. F. (Bombay).—Two serums are potent in plague if used early that of Lustig and the Yersin-Roux prepared at the Pasteur Institute Paris.

INFIRMARY.—In 1904 in London out of a total of 7,654 admissions of alleged lunatics only 3,716 were sent to asylums, and 3,156 discharged within 14 days.

THE DOYEN CURE FOR CANCER.

A facetious correspondent is answerable for the following:—

"The London doctors are enjoyin'
The great defeat of Dr. Doyen,
Who very likely felt 'kock-sure'
That he had found the Cancer Cure,
The 'Micrococci-neoformans'
Played the last act in that performance.
The boasted 'serum' failed to answer
Good-bye to Doyen's cure for cancer."

MR. W. WATSON.—The reduction referred to is due to the absence of epidemic diseases, which usually recur with the advent of the fruit season. There is a singular absence of deaths from diarrhoea so far, and there was not a single death from small-pox reported from any part of the United Kingdom last week.

H. R. H.—Your newsagent correctly reported to you that the numbers of this journal containing Prof. Taylor's articles on "The Diminishing Birth-rate" are out of print. We understand, however, that they have been reprinted in pamphlet form, and are still obtainable of the publishers, Messrs. Baillière, Tindall and Co.

ENQUIRER (Waterford).—We believe we are right in stating that the medical officer of a poor-law or of a voluntary medical charity is not entitled to demand a fee for giving evidence upon the death of a patient dying in the particular institution to which he is attached. If, as sometimes happens, a patient is brought dead to a voluntary hospital the resident medical officer gets a guinea for giving evidence and a guinea for post-mortem if necessary. As a general rule, the poor-law medical resident officer is forced by the Guardians at the time of his election to contract himself out of fees that he might otherwise gain for giving evidence as to deaths occurring outside his institution. This contract is grossly illegal. The Medical Defence Union is the only body we know likely to remedy the injustice. The General Medical Council defend nobody.

Vacancies.

The Victoria University of Manchester.—Junior Demonstrator in Physiology. Salary £100 per annum. Applications to the Registrar.

The Royal National Hospital for Consumption, Ventnor.—Senior Resident Medical Officer. Salary £20.0 per annum, with board and

lodging in the Hospital. Applications to the Secretary, 34 Craven Street, Charing Cross, London.

University of Leeds.—Faculty of Medicine.—Demonstrator of Bacteriology. Salary £150 per annum. Applications to the Registrar of the University.

Carlisle Non-Provident Dispensary.—Resident Medical Officer. Salary £150 per annum, with apartments. Applications to the Honorary Secretary, Mr. G. A. Lightfoot, 23 Lowther street, Carlisle.

Cheshire County Asylum, Macclesfield.—Junior Assistant Medical Officer. Salary £140 per annum, with apartments, board, and washing. Applications to the Medical Superintendent.

Roxburgh District Asylum, Melrose, N. B.—Assistant Medical Officer. Salary £140 per annum, with board, rooms, &c. Applications to Medical Superintendent.

Metropolitan Asylums Board, the Fever and Small-pox Hospitals.—Male Assistant Medical Officers. Salary £180 per annum, with board, lodging, attendance, and washing. Applications to the Clerk, Metropolitan Asylums Board, Embankment, London, E.C.

Bath Royal United Hospital.—Resident Medical Officer. Salary £100 per annum, with board, lodging, and washing. Applications to J. M. Sheppard, F.C.I.S., Secretary.

Royal Lancaster Infirmary.—House Surgeon. Salary £100 per annum, with residence, board, attendance and washing. Applications to the Secretary.

Ramsgate General Hospital and the Ramsgate and St. Lawrence Dispensary.—Resident Medical Officer. Salary £100 per annum, with furnished apartments, board, and attendance. Applications to H. W. Thornton, Secretary, Dispensary, Broad Street, Ramsgate.

Aston Union.—Resident Assistant Medical Officer. Salary £110 per annum, with furnished apartments, railings, and washing. Applications to John North, Clerk to the Guardians, Union Offices, Vauxhall Road, Birmingham.

British Hospital, Buenos Aires.—House Surgeon. Salary £200 per annum, with board, lodging, wine allowance, &c. Applications to Messrs. Arnold and Sons, 31 West Smithfield, London, E.C.

Lancashire County Asylum, Winwick, Warrington.—Assistant Medical Officer. Salary £150 per annum, with furnished apartments, board, attendance, and washing. Applications to the Medical Superintendent.

Appointments.

BELL, W. BLAIR, M.D., B.S.Lond., M.R.C.S.Eng., Assistant Gynaecological Surgeon to the Royal Infirmary, Liverpool.

BULLEID, EDGAR G., M.D., Clinical Assistant to the Chelsea Hospital for Women.

COOMBS, CAREY, M.D., B.S.Lond., Honorary Physician to Out-patients Royal Hospital for Sick Children and Women, Bristol.

DANIEL, PETER L., F.R.C.S.Eng., L.R.C.P.Lond., Assistant Surgeon to Charing Cross Hospital.

EASON, H. L., M.D., M.S.Lond., Assistant Ophthalmic Surgeon to Guy's Hospital.

HALL, OCTAVIUS, L.R.C.P. & S.Edin., L.F.P.S.Glasg., D.P.H.R.C.P.S. Irel., Medical Officer of Health of Devonport.

RUTHERFORD, V. H., M.A., M.B.Cantab., medical Officer to the Electrical Light and X-Ray Department, St. John's Hospital for Diseases of the Skin.

SAULTER, W. W., M.D., C.M., Clinical Assistant to the Chelsea Hospital for Women.

Births.

NEWINGTON.—On July 18th, at The Croft, Edenbridge, Kent, the wife of C. W. H. Newington, M.R.C.S., L.R.C.P., of a daughter.

Marriages.

BALFOUR—SPENCER.—On July 20th, at the Parish Church, Winsham, Somerset, Archibald Craig Balfour, L.R.C.P. & S.E., of Carr Bridge, Inverness-shire, son of the late George William Balfour, M.D. of Edinburgh, to Margaret Ellen, daughter of the Rev. D. H. Spencer, M.A., Vicar of Winsham.

FOULKES—FISCHER.—On July 20th, at Portsea Parish Church, Captain Thomas Howard Foulkes, F.R.C.S., Indian Medical Service, second son of the late Rev. T. Foulkes, of Salem, to Bertha, second daughter of Colonel Bowness Fischer, late Indian Staff corps.

KNAGGS—STILLWELL.—On July 18th, at the Parish Church, Hillingdon, Brevet-Major M. H. Knaggs, North Staffordshire Regt., son of Lt.-Col. Knaggs, to Constance Mary, youngest daughter of Dr. and Mrs. Stillwell, Moorcroft, Hillingdon.

LAW—CLAY.—On July 18th, at St. John the Baptist's, Broad Clyst, Devon, Horace Law, M.D., eldest son of the late T. Pakenham Law, K.C., to Sybil M. Clay, daughter of the late Sir George Clay, Bart., and Mrs. Holbeck, of Farnborough.

Deaths.

COLE.—On July 18th, at 12 Marlborough Buildings, Bath, Fanny, widow of the late Thomas Cole, M.D., F.R.C.P.Lond., of Bath, and daughter of the late Richard Gibson Davey, J.P., of Walmer, Kent.

LANE.—On July 21st, at 9 Gloucester Street, S.W., Rosa Mary, widow of the late Deputy Surgeon-General W. R. Lane, formerly Brigade Surgeon, Brigade of Guards, aged 69 years.

PHILLIPS.—On July 8th, at Pyrford Croft, near Woking, Surrey, William Page Thomas Phillips, formerly of The Grange and The Cedars, Melton, Suffolk, M.A.Oxon., J.P., D.L., barrister-at-law, only child of the late Benjamin Phillips, F.R.S., F.R.C.S., and Elizabeth (née Page), in his 72nd year.

AN IMPROVED METHOD OF VENTRO-SUSPENSION

OF THE UTERUS. (a)

By R. CHARLES B. MAUNSELL, M.B.,
F.R.C.S.I.,

Member of the Council of the Royal College of Surgeons, Ireland;
Surgeon to Mercer's Hospital, Dublin.

In bringing before you the following description of what I consider an improved method of ventro-suspension of the uterus, I will not enter into a lengthy discussion of the merits or demerits of operative treatment of uterine displacements, or of the various operations which have been performed, but I must briefly state my present position with regard to both these matters.

Many uterine displacements can be efficiently treated by one skilled in the application of pessaries, if the patients can be kept under observation for a considerable time. Many hospital patients and most patients sent from country districts require a shorter and more certain method of treatment. In neurotic individuals it appears to me to be better in many cases to perform an operation rather than submit them to repeated vaginal manipulations. Retroflexions require operation much more often than retroversions. When the lower abdomen has been opened for some other reason, it would appear best to remedy any retro-deviation before completing the operation.

With regard to the choice of operation—I have never performed vaginal fixation. Opinions, both written and spoken, of many obstetric authorities lead me to consider that parturition is more likely to be without accident following an abdominal rather than a vaginal fixation.

The Alexander operation is physiologically ideal, but pathology frequently negatives its accomplishment or mars its result. My opinion is that utero-fixation or utero-suspension, by the method to be described, will prove best in patients in whom pregnancy is not likely to follow. In those in whom pregnancy is likely or desirable either the Alexander operation or the following operation should give good results:—

Operation.—The abdominal wall having been divided, either by a vertical incision or by Pfannensteil's transverse method, the peritoneum

is incised either vertically or transversely according to whether complications are expected or not. The fundus of the uterus is grasped by a vulsellum and drawn forwards and downwards (see Fig. I).

FIG. I.

If the peritoneum has been incised vertically it is closed with a continuous fine silk suture as far as the protruding uterus, so that the uterus protrudes through a transverse slit, as in the alternative method of opening the peritoneum. The edges of the transverse peritoneal opening are united to the uterine wall by a continuous suture of fine silk. On the posterior surface of the uterus the line of suture should lie about three-quarters of an inch from the fundus and on the anterior surface about half an inch from the same point. Whilst the anterior suture is being introduced the uterus is drawn upwards by means of the vulsellum (see Fig. II.). The vulsellum is removed and the uterus falls back towards the pelvis, drawing the peritoneum into a narrow funnel-shaped depression (see Fig. III.), the sides of which can be readily approximated by a few sutures passed from side to side through the fascia and subperitoneal tissue, thus obliterating any dead space and preventing immediate contact of the uterus and abdominal muscles.

The abdominal incision is closed by continuous silk suture for the aponeurosis and subcuticular suture of silkworm gut for the skin. The advantages claimed for this operation are: (1) Firm support for the uterus without interfering with its

(a) Read before the British Gynaecological Society, July 13th, 1905.

mobility; (2) no interference with distension of the bladder; (3) should pregnancy ensue, the

FIG. II.

peritoneum will accommodate itself to the rising uterus and will contract again after delivery, not remaining as an elongated band, as the fibrous adhesions do in the ordinary ventro-suspension advocated by Howard Kelly and other operators.

FIG. III.

¶ The third claim is at present merely theoretical as the first of my patients was operated upon not longer than six months ago. The first and second claims are substantiated as fully as five patients, upon whom the operation has been performed, can substantiate them.

Introductory Lecture ON ANÆSTHETICS

WITH HISTORICAL SKETCH.

By THOMAS D. LUKE, M.B., F.R.C.S. EDIN.,

Lecturer on Anaesthetics, University of Edinburgh.

GENTLEMEN,—The chief aims of the medical profession have been well defined as—

(1) The relief of pain; and (2) the prolongation of life.

Naturally the first-named will make for the second.

(a) A Lecture given at the Royal Infirmary, Edinburgh, on May 4th, 1905.

One of the most common methods of relieving or preventing pain is the administration of a general anæsthetic. I propose to spend a few evenings of this summer session in explaining to you the theory and practice of anæsthesia, and if you will bear with me and give me your attention, I trust you will think the time not misspent.

Sir Frederic Treves has said with some truth: "The anæsthetist is made, not born like the poet." While quite admitting the fact to a degree, I would like to say that I feel very strongly we have all special bents in life. As some men are good golfers, others brilliant chess players, so in the profession we find one man a born lawyer, others interested in nothing but scientific chemistry. Sir Robert Finlay is a striking instance of an inborn legal bent. He graduated M.D. of this University to please his father, and subsequently took to law—with what result you know. Now, while I know that some of you will take more readily and happily to giving chloroform or ether than some of your fellows, I most distinctly feel there is nothing in the administration of either which any man of ordinary intelligence cannot master with a little application and guidance—you must have practical experience and guidance along with it.

To quote Sir Frederic Treves again, "There is a fairly widespread impression that to give chloroform is a minor act—that the power, if worthy of the name, comes to a man with the granting of his diploma." Men are wont to say, "Well, if a chap can't give chloroform, what can he do?" If you start on methods of your own, uninfluenced by the landmarks afforded by physiology you will fail, and go from bad to worse; if you regard the surgeon's work, keep up a running conversation with the nurse, or allow yourself to drift into a reverie on the law of gravitation, you will also fail.

Every anæsthesia must be undertaken with all seriousness and a sense of individual responsibility on the part of the administrator. The surgeon has his work, often very extensive, cut out for him, and requiring his undivided attention, and be the anæsthetist a student, a house surgeon, practitioner or specialist, he is and must be individually responsible. The very rapidity and ease with which chloroform acts often gives a beginner a false impression. Let him bear in mind he is handling a two-edged sword, and let all his power of observation be concentrated on the thing on hand. We all know that accidents happen with every anæsthetic, and I am afraid some always will happen; a certain percentage is practically unavoidable whatever precautions are taken. But I am quite certain that the larger proportion are avoidable, and are due to bad methods and therefore ignorance, and above all to haste and want of proper sense of the risk incurred. In Sir James Paget's Memoirs, he refers to the lamentable state of mind and remorse which a doctor is reduced to if in one of these emergencies or crucial moments, which come in every man's practice, he fails to succour a patient or do the right thing from ignorance or from not taking advantage of the opportunities of his student days. There can be no better illustration of this than malpraxis in chloroform emergencies. If you lose your head you lose your patient, and if you are in general practice, your local reputation will suffer enormously. A man may forgive you if his wife dies in your hands from difficult labour or even puerperal fever, but if of chloroform, never.

The need for thorough instruction of all aspirants to the medical profession in anæsthetics has so far only been recognised and insisted on by a portion of the Examining Boards and Universities; while it is unfortunately extremely rare for any attempt to be made to test the candidate's knowledge of this subject, even in the qualifying examination.

Year after year men become qualified to practise medicine without even having attended a lecture on the subject or personally administered any anæsthetic. There is no question that to this fact is due a very large number of the fatalities which annually occur under the influence of narcotic vapours.

What is a general anæsthetic ?

It is a substance which has the power of destroying conscious sensibility throughout the organism—but most anodynes, narcotics, and soporifics, given in sufficient doses effect this. Accordingly such a definition is scarcely complete.

We require the following properties in a general anæsthetic :—

1. It must be able to produce general loss of sensation.
2. It must be of such a nature as to be capable of being readily introduced into the circulation without any considerable degree of discomfort to the patient.

3. It must produce its effects gradually and progressively, and so be readily under the control of the administrator.

4. It must bring about not only general sensory paralysis but such a loss of motor power as to render the performance of surgical operations practicable.

5. Its action on the sensory and motor systems must not be associated with greater excitement, convulsive movement, or any interference with respiration, circulation, or any other important vital processes than can be readily controlled by the anæsthetist.

6. Finally, it is a *sine quâ non* that the agent employed shall be of such a nature that when it is withdrawn the whole organism will resume its functions, and return to that condition in which it existed when the anæsthetic was first applied.

The agents known to best fulfil such conditions are nitrous oxide, ether, chloroform, chloride and bromide of ethyl.

General surgical anæsthesia may be defined as a state of profound insensibility, brought about by the action of a general anæsthetic, and of such a character as to allow of the performance of any surgical operation painlessly.

ANCIENT METHODS OF PRODUCING ANÆSTHESIA.

We are unable to trace any evidence of the most rudimentary knowledge of true anæsthetics such as we now use further back than the dawn of the last century, but we find it was customary to endeavour to allay the pain of operative procedure by the internal administration of drugs in ancient days.

We can in the very earliest writings of the ancients find allusions to the use of *Mandragora*—or mandrake, a plant allied to belladonna or deadly nightshade. A wine of mandragora was used by the Romans to relieve the sufferings of the crucified, and it is maintained by the divines that it was either this preparation or one of Indian hemp which constituted the "vinegar on a sponge offered to our Saviour on the Cross."

Pliny speaks of mandragora as follows: "If anyone eat of it he will immediately die, unless he be treated with butter and honey, and vomit quickly." Further, if anyone is to have a member mutilated, burnt or sawn off, "let him drink half an ounce with wine, and let him sleep until the member is cut away without pain or sensation." Dioscorides, speaking of the plant, also says: "Medical men use it when they have to resort to cutting or burning." The late Sir Benjamin Ward Richardson, after a lapse of many centuries obtained a fine specimen of mandragora root, and after making wine from it, and testing it, found it was a narcotic having precisely the properties which the ancients ascribed to it.

Indian Hemp: "Bhang or "Gunyah." There seems to be no manner of doubt that this still highly valued drug was from the earliest days used for pain-killing purposes. Some years ago an old Chinese manuscript was laid before the French Academy by M. Julien, in which the use of Indian hemp for annulling pain in surgical operations is mentioned as having been resorted to by a medical practitioner named Hoa-tho as early as the third century, 300 A.D. A preparation of this drug is what is probably referred to by the prophet Amos, 700 B.C. as "the wine of the condemned." In most Eastern countries it has been used extensively by criminals condemned to suffer torture.

Opium was employed in later years to dull the senses of the patient prior to operation, and Mr. Annandale tells me that even so recently as his student days he

remembers the administrations of laudanum and whisky before chloroform came into such general use in Scotland.

In 1784 a certain Dr. Moore proposed to bring about local anæsthesia of limbs during surgical operations by compressing the nerves supplying them. He tried this method in a case in Dr. Hunter's practice, and applied a tourniquet for an hour before operation, to compress the nerves, with, however, partial success. Malgaigne also tried this method but necessarily without much success, for the compression of the nerves themselves causes considerable pain, as any of you who have seen an aneurysm treated by compression will realise—and further the prolonged application of compression naturally will cause vascular stasis and tendency to gangrene.

Again Morgagni, Hoffman, and others used digital compression of the carotid arteries to diminish the blood supply of the brain and so produce complete or partial anæsthesia. This method undoubtedly produced stupor or coma with remarkable rapidity, and is practically identical with the *modus operandi* in present day "garotting." Further, it is quite commonly used in the East—Burmah, Java, and Sumatra—though scarcely for orthodox purposes.

An officer in the Indian Medical Service wrote to the *British Medical Journal* in August 1902, describing a very interesting exhibition of this mode of producing anæsthesia, of which he had been a witness in 1884 while going from Moulmein to Rangoon on a coasting steamer. The operator was a Burmese juggler from Mandalay, who performed a number of very clever tricks, most of which were quite new to the majority of European passengers. He asked an English officer to order his Madrassy servant to sit down on the deck, and this being done he now told the audience he was going to show them how the dacoits or professional native robbers rendered their victims insensible. His next move was to seat himself in front of the servant, and after telling him not to be afraid he seized his neck with his hand on either side, and with his thumbs firmly compressed the soft parts below the angle of the jaw against the spine. Immediately the man operated on got tremulous and limp, and in a short time fell back on the deck as if in a dead faint. At this stage some of the lady passengers became greatly alarmed, and seeing this the juggler speedily resuscitated the unconscious man by slapping him on the face with a handkerchief. The man rose from the deck and walked off, though with a somewhat unsteady gait. The unconsciousness was evidently produced by digital compression of the carotids causing temporary cerebral anæmia. This method while effectual, is by no means free from risk. Dr. Joseph Bell tells me he tried it experimentally on a friend many years ago, and had some considerable difficulty in bringing him round.

[A short account followed of the discovery of nitrous oxide, at first by Davy, and then its introduction into dental practice by Wells; of Morton's discovery of the anæsthetic properties of sulphuric ether, and of Simpson's work in introducing chloroform as an anæsthetic agent in Scotland.]

What has anæsthesia done for the world at large, and for the medical profession, in addition to having actually relieved or prevented pain and shock in some millions of cases? What was the position of the subject in the early days of the discovery, and how does that position compare with the present? What operations were to the patient in pre-anæsthetic days has been vividly described by one who had himself come under the surgeon's knife in those days. The following are extracts from a remarkable letter written to Simpson by an esteemed professional colleague who holds a distinguished place in British science and literature:—

"Several years ago I was required to prepare on very short warning for the loss of a limb by amputation. A painful disease, which for a time had seemed likely to yield to the remedies employed, suddenly became greatly aggravated, and I was informed by two surgeons of the highest skill, who were consulted on my case, that I must choose between death and the sacrifice of a

limb, and that my choice must be promptly made, for my strength was fast sinking under pain, sleeplessness, and exhaustion. I at once agreed to submit to the operation, but asked a week to prepare for it. The week so slow and yet so swift in its passage, at length came to an end, and the morning of the operation arrived. There were no anaesthetics in those days, and I took no preparative stimulant or anodyne of any kind, unless two cups of tea, which, with a fragment of toast, formed my breakfast, be considered such. The operation was a more tedious one than some which involve much greater mutilation. It necessitated cruel cutting through inflamed and morbidly sensitive parts, and could not be despatched by a few swift strokes of the knife. I do not suppose that it was more painful than the majority of severe surgical operations are, but I am not, I believe, mistaken in thinking that it was not less painful, and this is all I wish to contend for.

"Of the agony it occasioned I will say nothing. Suffering so great as I underwent cannot be expressed in words, and thus fortunately cannot be recalled. The particular pangs are now forgotten; but the black whirlwind of emotion, the horror of great darkness, and the sense of desertion by God and man, bordering close upon despair, which swept through my mind and overwhelmed my heart, I can never forget, however gladly I would do so. Only the wish to save others some of my sufferings makes me deliberately recall the anguish and humiliation of such an experience; nor can I find language more sober or familiar than that I have used to express feelings which, happily for us all, are too rare as matters of general experience to have been shaped into household words.

"Further, during the operation, in spite of the pain it occasioned, my senses were preternaturally acute, as I have been told they generally are in patients in such circumstances, I watched all that the surgeons did with a fascinated intensity. I still recall with unwelcome vividness the spreading out of the instruments, the twisting of the tourniquet, the first incision, the fingering of the sawed bone, the sponge pressed on the flap, the tying of the blood-vessels, the stitching of the skin, and the bloody dismembered limb lying on the floor. Those are not pleasant remembrances."

Before the days of anaesthetics a patient preparing for an operation was like a condemned criminal preparing for execution. He counted the days till the appointed day came. He listened for the echo on the street of the surgeon's carriage. He watched for his pull at the door-bell; for his foot on the stairs; for his step in the room, for the production of his dreaded instruments, for his few grave words and his last preparation before beginning. And then surrendered his liberty, and, revolting at the necessity, submitted to be held or bound, and helplessly gave himself up to the cruel knife. The excitement, disquiet and exhaustion thus occasioned could not but greatly aggravate the evil effects of the operation which fell upon a physical frame predisposed to magnify, not to repel, its severity.

In Sir James Paget's "Reminiscences," he refers to the horror occasioned to his wife and her guests at afternoon tea-parties by the screams and cries of the victims of the operating knife in the theatre which was adjoining to their residence in Bartholomew's Hospital.

Why do not deaths from anaesthetics show signs of diminution? During the last ten years there have been double the number of deaths in this country of the preceding decade, which is clearly out of proportion to the increased use of anaesthetics. In 1897 alone there were no less than 95 recorded deaths. How many unrecorded we do not know. The reason chloroform is far too frequently chosen as the anaesthetic when safer agents, such as N_2O and ether, should be used is that the responsibilities involved in administering anaesthetics are not yet fully realised. The administration is too often placed in the hands of comparatively unskilled men; and further, the natural tendency possessed by patients under anaes-

thetics to become the subject of obstructive breathing is not yet sufficiently recognised.

It can never be too firmly insisted that the pouring out of a certain quantity of liquid anaesthetic upon a towel or lint and holding near a patient's face does not and never can constitute the safe and skilful administration of an anaesthetic. It is quite possible that a certain number of such cases may, by good fortune, be unattended by any obviously bad result; but a practical knowledge of the varying rhythm displayed by the respiration under nitrous oxide, ether, and chloroform, with the exact import of every change in its character; of the many kinds of obstruction to efficient oxidation which may arise; of the mechanical effect of posture upon the circulation, and the impediments which certain positions of the body present to the free movements of the diaphragm, thorax, and abdomen; the recognition of the absolute necessity for mouth gag, tongue forceps; and even tracheotomy instruments being at hand during every general anaesthesia, for whatever purpose it may be undertaken; these with unremitting attention to the symptoms as they arise, and instant elimination of asphyxial elements are absolutely necessary factors in the making of a skilled administrator.

Mr. Marmaduke Sheild, Surgeon to the London Hospital, has admirably summed up the position of the general practitioner as regards anaesthetics:—"The difficulty suggests itself as to what cases or class of cases it is justifiable for a man of ordinary knowledge and experience to undertake. The answer is obvious—

"In districts remote from large cities, it is the duty of every man bravely to encounter difficult and dangerous cases, and to do his best by them. In other circumstances the rule is widely different."

If medical men were well educated in the theory and practice of anaesthesia, they would recognise for themselves that for nose and throat operations, associated with severe haemorrhage, for cases where the breathing is embarrassed by aneurysm or tumour, or for prolonged abdominal operations, the administration of the anaesthetic should be entrusted to those who have given more than ordinary time and attention to the subject. The satisfactory administration of anaesthetics in many cases of disease, e.g. empyema, is fraught with risk. Safety to the patient and comfort to the operator can only be insured by long experience, caution, and skill. It is quite impossible to suppose that all medical men can be educated to such a high pitch of excellence. They should, however, be enabled during their hospital career to attain a sufficient knowledge to fit them to estimate the limit of their own capabilities, and to know when a given case is difficult or dangerous. If once the young practitioner grasps the fact that every case of anaesthesia is a study in itself, in the selection of the appropriate agent, for safety, and for the operator's convenience, fully appreciating that every case has its peculiar risks and after dangers, he would continue to improve as years advance. At all events, his medical teachers will have done their duty by equipping him as well as possible for one of the most important after duties of his professional life."

THE RAW MEAT TREATMENT OF TUBERCULOSIS.

By GEORGE PETIT, M.D.,
Of the Faculty of Medicine of Paris.

WEISS, of St. Petersburg, was the first to introduce meat as a therapeutical agent, subsequently applied to the treatment of tuberculosis by Fuster, of Montpellier. Richet and Héricourt, having instituted a series of experiments on dogs, concluded that raw mutton, in doses of from six to nine ounces in the twenty

four hours, delayed the progress of tuberculosis, and, on the strength of their observations, tuberculous patients were fed on meat-pulp, either pure or mixed with mashed potatoes, lentil flour, sugar, &c. The method, however, did not give any very striking results, and soon the employment of raw meat became limited to the "præ-tuberculous." Moreover, some practitioners allowed it to be lightly grilled, thus rendering it less repulsive to take, while others preferred meat powder. The raw meat treatment of tuberculosis has its ardent partisans, and its not less ardent detractors. It has not become popular, probably because it is so frequently objected to by patients, and also because of the recognised dangers attending the ingestion of uncooked meat.

The general impression appears to be that the physiological data upon which the raw meat treatment was originally introduced were incorrect, an opinion based upon the disappointing results of hyperalimentation. It is even alleged to fatigue digestion and to disturb the organism by increasing the quantity of waste products, toxins, excreta, and fermentations, the increased oxidation thus induced tending to precipitate the wearing out of the organism. Under these circumstances the organism is "consumed," and after a period of apparent improvement the disease takes on a more rapid course.

The disfavour into which the raw meat regimen has fallen is to some extent the consequence of the exaggerated claims advanced by its partisans who wished, to the exclusion of all other kinds of food, to make raw meat the panacea for tuberculosis, a panacea not only infallible, but exclusive.

Dr. Edmond, however, points out that the use of raw meat does not necessarily exclude the administration of other aliments, variety of food being at least as important as quality. Oils, fats, and farinaceous articles act as calorific agents by providing the carbon necessary to combustion which is the fundamental feature of organic life. Fruit, green vegetables, and milk add to the resources at our disposal, although they can only be regarded as accessory. The practitioner's great object must be to awaken the appetite when this is defective, for if we can only get the patient to eat, digest, and assimilate well, we may hope to see the disease arrested. In the contrary event, the chances of recovery are small. The gastric state of the tuberculous renders it impossible to generalise any one method, and the monopolisation of any one therapeutic method strikes one as absurd in the light of our present knowledge.

Foods will be assimilated and utilised the more readily the more easily they are digested. Vegetable albumin is less easily digested than albumin of animal origin, and certain structures—bone, cartilage, and elastic tissue, the flesh of certain animals and fish roe, are with difficulty, if at all, assimilable. Experience has shown that we cannot give an equal volume of vegetable albumin in lieu of animal albumin, for if we do so the patient loses weight. Admitting that it is important to nourish the tuberculous well and fully, there is no necessity for hyperalimentation; in other words, we must stimulate functional activity to assist nutrition without, however, unduly taxing that function. Exaggerated alimentation is not an exchangeable term for hyperalimentation. Superabundant alimentation, when in excess of the requirements of the organism, soon brings about disturbances of nutrition, and is productive of arthritis or obesity. Huchard and many others have insisted on the dangers associated with the raw meat diet which determines hepatic congestion, with dyspepsia, biliary and renal lithiasis, arterial hypertension, and arterial sclerosis. Then, too, the tuberculous subject undergoes the rest cure coincidentally with the hyperalimentation, thus creating an unfavourable state of things, a flagrant opposition between clinical observation and therapeutical application. Adipose tissue, says Garnier, is the one that undergoes most marked development when carbohydrates are given, but fats which are less readily assimilated than carbohydrates are also stored

up in adipose tissue. When we aim at producing fat we ought to have recourse to fatty fish, vegetable soups, sugar, wine, &c.

Turning, however, to the subject under consideration, viz., the use of raw meat in the treatment of tuberculosis, I will briefly give the results of my personal observations. My patients for the most part had been advised to adopt this regimen, or had done so *proprio motu*.

We must not overlook the fact that we ought to give the organism only such aliments as it can turn to account and the stomach only what it can digest. According to Dujardin-Beaumetz the nourishment of convalescents should, above all, be substantial and reparative, the nitrogenous elements should predominate, but care should be taken to commence the regimen with the most digestible articles, gradually returning to the normal alimentary regimen of the healthy man. Crude aliments, such as meat, milk, eggs, &c., are not always suitable for a nitrogenous regimen by reason of the insufficiency of gastric juice obtained in many maladies and in convalescents. The integrity of the gastric secretion is obviously highly important in respect of digestion and especially of assimilation, and in tuberculosis this integrity of function is almost always more or less in default. Dr. A. Robin, having examined the gastric juice in eighty-five tuberculous patients at various stages of the disease, found, in the first period, gastric hyperæsthesia with excess of acid, the total acid being increased. To these initial secretory troubles succeeds a deficiency of solid acid, and we get chronic gastritis in the cavernous stage, characterised by atrophy of the gastric glands, which are strangled by the overgrowth of the connective tissue. In the course of chronic pulmonary tuberculosis it is possible to observe a sort of gastric cycle beginning with stimulation of the function, and culminating in total abolition of the function. These modifications of secretion are directly related to disturbances of blood pressure, and may perhaps explain the frequency of hæmoptysis of alimentary origin in tuberculous patients, described by Dr. Sabourin. Patients who are ordered hyperalimentation have only one thing in view, viz., to gorge themselves with red, roast, grilled, underdone or raw meat, to the exclusion of other articles of food, and in certain of these patients we witness recurrent attacks of hæmoptysis. These attacks of hæmoptysis occur without apparent cause, and recur even while the patient's general condition seems to be improving. The hæmoptysis often ceases on a change of diet. Then, after a few days' rest, the patient resumes his tonic alimentation and sooner or later the bleeding is repeated. In hæmoptysis of alimentary origin one observes temporary cloudiness of the urine preceding the hæmoptysic crisis by a few days, and persisting so long as the latter lasts, should no change of diet intervene. This urinary phenomenon is a sign of the greatest importance, for it is the outward and visible manifestation of the "surfeit" of the organism.

I had long observed these various phenomena, and I endeavoured to ascertain their cause. I noticed that under the influence of a raw meat diet marked phosphaturia was produced, with an increase in the excretion of urea, almost always coinciding with hyperacidity of the urine; moreover, the greater the hyperalimentation the greater the fall in urinary acidity. My observations therefore, seem to show that the raw meat diet gives results just the opposite to those aimed at, in other words, that "the more the tuberculous patient overfeeds the greater is his denutrition." These facts confirm the results obtained by Dr. Robin in respect of the demineralisation of the organism in those predisposed to tuberculosis, whence the necessity of combating this demineralisation in the præ-tuberculous and in the tuberculous during the first and second periods of the disease. In all probability this demineralisation facilitates the invasion of the organism by the tubercle bacillus and creates a *milieu* favourable to its development.

Recent researches have given us clear and precise

ideas in regard to disturbances of nutrition. We know that if any one of the principal functions of the economy, such as of the nervous system, digestion or respiration, gets out of order, the organism as a whole is thrown out of gear. There is a leakage of organic salts, the very salts that form an integral constituent of the cells, a loss that is manifested in a urological syndrome in which phosphatic waste holds the first place. At the same time the alimentary phosphates and lecithins are incompletely assimilated and nitrogenous metabolism is diminished. These disturbances of the exchanges are very common, and almost invariably accompany diseases of growth, neurasthenia, albuminuria, phthisis and all febrile affections. In order that the ultimate absorption of the aliments shall take place, all the preliminary operations must be duly effected under normal conditions, each organ must have contributed its quota of work and special secretion on the passage of the alimentary products.

When this is not the case, when the aliments in their passage through the organism meet with diseased organs which do not provide, or only in part, their share of work and special elements, the multiple operations which, together, constitute digestion, are badly and incompletely performed and the aliments arrive incompletely transformed, and in a state ill-suited for absorption. That is so much lost to nutrition, and so much material to undergo fermentation, and consequently to become injurious instead of of being useful.

Dr. Doléris maintains that the abuse of nitrogenous food is the cause of nearly all the diseases of nutrition. He regards "albuminism" as more dangerous than alcoholism, for only the drinker makes an abusive use of alcohol, and he is perfectly aware that he is doing wrong, while in respect of albumin, most human beings indulge therein in good faith, convinced that they are thereby increasing their strength and averting starvation of their tissues. It is obvious, then, that no general rule can be laid down for the alimentation of the tuberculous in whom, for the most part, the digestive organs are so weakened as only to allow of very moderate nourishment.

This is one of the strongest arguments against forced alimentation, the abuse whereof even in healthy individuals, is contrary to the elementary laws of personal hygiene. This is more than enough to condemn forced alimentation, which is capable *per se* of determining a morbid state *à fortiori* of aggravating pre-existing disease.

In health, says Dr. Blanc, the vital expenditure is compensated by the equivalent of daily nourishment, but when disease supervenes there is a more or less pronounced increase in the expenditure. To the waste produced by the outgoings we oppose a superabundance of intake, in the form of forced alimentation, but we have to ask ourselves, what is the value of this intensive nutrition as applied to animals?

In animals subjected to the fattening process the mortality is from 15 to 20 per cent., and when the object has been attained, when they are "ripe" for the table, few among them could withstand many more days of the special regimen. No doubt in certain cases the method has given beneficial results in human beings, but it is none the less recognised by experienced observers that the results are usually negative, when not actually injurious by precipitating the fatal termination in patients who, but for the regimen, would have survived for a time longer. Gastro-enteritis, hepatic hypertrophy, renal inflammation, nervous disturbances and cutaneous troubles are common results of this process, and when patients tolerate it there is almost always excessive production of urates. It is a matter of common knowledge that incomplete combustion of the aliments is one of the great causes of gravel, obesity, diabetes, and other formidable complications.

It should be remarked *en passant* that we are not dealing with hyperalimentation by ordinary foods, that is to say, foods to which the organism is accustomed, but of raw meat, which is quite a novel diet. Under

these conditions, denutrition takes place much more rapidly, as is evidenced by the phosphaturia constantly observed in persons subjected to the raw meat diet.

Dr. F. X. Gouraud, having given special attention to phosphatic exchanges in normal and in diseased organisms, says: "Certain suspicious-looking specimens of urine, cloudy, it may be, owe their appearance to the presence of phosphates in suspension. It does not follow that there is phosphaturia—*i.e.* excess of phosphates in the urine; under certain conditions the phosphates are spontaneously precipitated, even though present in normal proportions. That happens when the urine, instead of being acid, is alkaline, simply because certain phosphates are but feebly soluble in alkaline media. It also occurs when phosphates, without being in excess, are present mostly in the form of earthy phosphates (phosphate of lime), because these are but slightly soluble, much less so than the alkaline phosphates (of soda). Consequently, just as the spontaneous precipitation of uric acid in no wise implies a real excess of the acid so the spontaneous precipitation of phosphates does not necessarily imply an excess thereof. Chemical examination, therefore, alone enables us to prove the existence of phosphaturia or hypophosphaturia. The phosphaturia in question is ephemeral. True, protracted phosphaturia is more particularly associated with the following pathological states: dyspepsia, tuberculosis, diabetes, and neurasthenia. In such cases phosphaturia is of primary importance as a guide to diagnosis, prognosis, and treatment.

Moreover, it has always seemed to me that the hypoacidity consequent upon hyperalimentation by raw meat was specially well-marked in tuberculous subjects, still possessed of a certain consistency of the tissues, those sufficiently well provided with adipose tissue to pass for fat. In thin tuberculous patients the raw meat regimen is followed by a fallacious period of apparent increase of weight, promptly followed by physical deterioration due to hyperoxidation of the cells accompanied by marked repulsion for all kinds of food, so that we not only fail in our object, but render subsequent alimentation difficult or impossible. In the same way I have observed in several cases of treatment by raw meat acute attacks of toxæmia simulating acute tuberculosis, in which improvement followed cessation of the regimen and its substitution by milk. As soon as the organism has recovered itself I put these patients on a milk-vegetable diet. Well-cooked bread is an excellent food for the tuberculous; the crust contains 13 per cent. of nitrogenous matter and 67 per cent. of starch, and is rich in nuclein and phosphated principles. Leguminous flours, diastased or not, are equally useful in making good the loss of phosphates, nitrogen and carbon, which is exhausting the patient (Gautier). Herbaceous vegetables have the advantage of overcoming constipation, and they introduce iron as well as lime and magnesia. Feculents rich in nitrogen, peas, lentils, haricots, and alimentary pastes, are useful adjuvants of hyperalimentation.

In spite of the willingness of the patient, in spite of a well-thought-out dietary, it often happens that hyperalimentation is impracticable. Dyspeptic disturbances supervene, with *œtid* diarrhoea, symptoms of auto-intoxication, and scanty urine, and one is constrained to modify the regimen. In such cases the patient is put on milk, and the question of alimentation has to be reconsidered later on.

Another method for ascertaining the effects of particular regimens is based on the determination of the urinary co-efficients. It consists in making quantitative analyses of the urine and founding one's plan on their relationship in point of proportion. In this way we measure, not the actual intake of alimentary substances, but the quality of the functions. The most useful data are the following:—(1) The proportion of nitrogen excreted in the form of urea compared with the total nitrogenous output; (2) the proportion of total carbon output compared with the total nitrogenous output; (3) of the weight of urea compared

with that of the total fixed matters; (4) of uric acid to urea; and (5) of the mineral constituents of the urine to the total of fixed matters.

I do not wish, however, to insist on the toxic phenomena that may follow the abuse of raw meat, since these are familiar to all. I will simply draw attention to the diminution of the total acidity, and of phosphoric acid in particular, in contrast with the exaggerated excretion of urea without any notable change in the total quantity of urine.

According to Dr. Maurel, 4.055 gr. of phosphoric acid per kilogramme is sufficient for the organism under ordinary conditions of wear and tear, and this quantity is contained in the ordinary diet. The quantity of acid eliminated in the urine rarely falls below 1 gramme, equal to 0.016 gr. per kilo., even if the quantity in the food be much reduced. It is necessary to bear this clearly in mind in seeking to explain the conditions under which the normal figures are modified. In the elements of the tissues phosphorus exists in combination with the proteid constituents of protoplasm, and, like the latter, undergoes an oxidising process which throws it out in the course of disassimilation. The daily loss from the wear and tear of the tissues, *i.e.* the oxidation of the organic phosphatic compounds, is represented by about 2.50 gr. of phosphoric acid. This loss is made up by the phosphorus contained in the food, animal and vegetable. In vegetables, as in animals, the parts of the plant in which there is most vitality, the buds and seeds, for example, are richest in phosphorus. It seems much more reasonable, from many points of view, to take the phosphorus of which we stand in need from vegetables. Although man is omnivorous, it is from the vegetable, rather than from the animal, kingdom that man draws the mineral elements necessary to his maintenance. Meat contains them, it is true, but in less quantity, and their utilisation entails greater digestive activity. The vegetable kingdom, by a synthetic process, transforms the phosphorus which it takes from the soil into organic compounds, such transformations being essential to plant-life and growth. Experience shows that the organic compounds formed in plants are admirably adapted to stimulate the phenomena of development in growing animals. Young animals whose growth it is desired to promote are fed on cereals and leguminosæ, with young shoots of the graminacæ in which the organism finds the organic phosphates which stimulate its activity and nutrition. (Petit and Thezard.)

If, then, we take into consideration the fact that phosphoric acid is the element most lacking in the food, and that all other elements are only assimilated in proportion to the quantity of this body present we shall at once grasp the importance of ensuring an adequate supply thereof. Before any other treatment we must make sure of obtaining a certain acidity and a certain degree of phosphatisation. In the absence of this principle no chemical task can be undertaken and no medication can do good. That is the principal cause of the failure of certain methods of treatment which, if successful in some, are unsuccessful in others. The use of raw meat diminishes the acidity and thereby hinders assimilation, and by exaggerating the elimination of urea weakens the resistance of the organism and promotes toxæmia. My conclusion is that in tuberculous subjects the use of raw meat should be strictly prohibited, more particularly in the præ-tuberculous and in tuberculous children, such prohibition admitting of no exception.

Clinical Records.

CASE OF URETHRAL CYST. (a)

By H. MACNAUGHTON-JONES, M.D., M.Ch., F.R.C.S.
I. & E.

A PATIENT, æt. 34, a widow, consulted me for pain in the urethra, and frequency of micturition, the

bladder having to be relieved every few hours, sometimes oftener, with constant escape of urine at times. The pain was especially severe after urine had been passed. It was intensified during the catamenial period.

On examination, I found a swelling about the size of a walnut occupying two-thirds of the urethral canal, beginning a short distance behind the meatus in the urethro-vaginal septum.

The diagnosis lay between a urethrocele, a diverticulum of the urethra and a cyst. On passing a sound into the urethra, though it could be felt close to the cyst wall, it could not be passed into the sac. The question then arose if the cyst were congenital, a development of such as has been described by English, who found them in the newly-born, and here developed into a larger size in after life; or, secondly, a true urethral diverticulum, in which all the urethral coats are present, a weakness occurring at some one joint, as described by Lannelongue and Priestly; or, thirdly, a dilatation of a lacuna of Morgagni, the result of inflammation with closure of its orifice and subsequent dilatation, as described by Winckel. The position of the sac was against its being due to dilatation and occlusion of Skene's tubules.

On re-examination at the operation under an anæsthetic, I came to the conclusion that it was a cyst. Mr. Targett, who was present, agreed. On isolating the cyst wall, characteristic cystic fluid escaped. I worked round the sac, hoping to separate it completely from the urethral mucous membrane. This, however, I found to be impossible, as the deep portion of the sac consisted of the dilated urethral wall, and this was removed in extirpating the cyst. I had now to make the posterior urethral wall by a plastic operation. This I succeeded in doing, finding sufficient mucous membrane to form the canal, and covering over the vaginal surface with the vaginal membrane. This was done over a stout sound. I inserted a glass catheter, and emptied the bladder of some retained urine. The patient was carried into bed. She was a very stout woman, weighing some 14 stone, and unfortunately, in her removal from the table the catheter was broken, half remaining in the bladder. A rubber catheter was inserted and retained. The following day, under an anæsthetic, I explored the bladder, and found that the broken catheter was lying posteriorly and low down. On the next day I performed suprapubic cystotomy, removed the half of the catheter, found that the two pieces fitted accurately, and closed the wound completely without drainage. It healed by primary union. During the time of healing, the urethral wound had re-opened. I did not interfere with it again until April 3rd, the patient in the meantime having gone to the country to recruit, and though the urethral canal was incomplete for over an inch, the sphincter of the bladder being in no way interfered with, she had much less pain and discomfort than before admission.

On April 3rd, I performed another plastic operation, and this was so far successful that only some three-eighths of an inch of the urethral canal was now exposed. On May 13th, I again operated, and brought the opening to within a quarter of an inch of the meatus. As the patient had now complete control and power of retention with perfect comfort for six hours, I did not interfere again. The case is interesting, both from the histological and the operative point of view. I think that the cyst was undoubtedly one of congenital origin; the urethra forming part of the cyst wall. Should I again meet with a similar case, which is not likely, I should have learned my lesson in remembering this during the dissection. Her own statement of her present condition is as follows:—
"I am glad to tell you I am feeling better than I ever did. I can retain my urine quite well five or six hours."

THE tenth International Anti-alcohol Congress will be held at Buda-Pesth from September 11th to 16th. Professor Gruber, of Munich, will deliver an address, entitled "The Hygiene of the Ego."

(a) Read before the British Gynæcological Society, July 13th, 1905.

Transactions of Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD THURSDAY, JULY 13TH, 1905.

DR. WILLIAM ALEXANDER, President, in the Chair.

DR. MAUNSELL read some notes on an improved method of

VENTRO-SUSPENSION OF THE UTERUS,

which will be found with illustrations on pp. 103-4. In the discussion which followed

DR. MACNAUGHTON-JONES said that he thought it would be better to restrict the term "ventro-fixation" to those cases where the uterus was fixed to the abdominal wall outside the peritoneal and sub-peritoneal fascia—a method which he considered should only be adopted after the child-bearing period. The term "suspension" it would be better to reserve for Kelly's more recent method, and those operations of an intra-abdominal nature in which the uterus was not fixed, but where traction was exerted through the round ligaments. The Alexander-Adams operation was the ideal operation during the child-bearing period in a free, mobile, and not very large uterus. He thought the abdominal method was always to be preferred where the adnexa were affected or exploration was demanded. In such cases he had for some time been in the habit of performing the following operation, and had hitherto had no case of failure. After the adnexa have been examined, and dealt with according to circumstances, the uterus is brought well forward—and the round ligament of one side is hooked on the finger, a fairly thick gut ligature being passed through the peritoneum and sub-peritoneal fascia. The ligature then takes in the loop of the round ligament. The two ends of the ligature are caught in the forceps, and allowed to drop over the side. The same procedure is carried out on the opposite side. The wound and exposed cavity having been carefully cleansed, the inner end of one of the ligatures is now carried from within out through the peritoneum and sub-peritoneal fascia at the opposite side, and the same is done with the other. The two ligatures thus cross, either holding a loop of the round ligament close to the uterine cornua. The peritoneum is now sewn with cumol gut, and the ligatures holding the round ligaments are tied *en route*, after which the abdominal toilet is completed. If the uterus be exceptionally heavy, and there has been an old retroflexion, a Kelly's suture is passed in addition to the posterior surface of the uterus, and this is tied with those of the round ligaments.

The PRESIDENT said he did not wish to speak himself, because he was prejudiced in favour of his own method.

DR. HODGSON remarked with regard to the Maunsell suspension that the upper line of sutures when closed together at the sides made a *cul de sac*, which in the event of infection might be troublesome.

DR. HEYWOOD SMITH said that Dr. Maunsell, in his description, spoke of a row of sutures inserted along the anterior portion of the fundus, and another along the posterior, while Dr. Macnaughton-Jones, referring to the extra ligature put in, also referred to Dr. Kelly's method of carrying stitches through the posterior aspect of the fundus too. He (Dr. Heywood Smith) wished to ask whether, in the case of pregnancy arising, ventro-suspension would not be better if it were limited to the anterior portion of the fundus and not the posterior? When the posterior portion was brought close to the abdominal wall, the fundus almost rested on the os pubis. He would like to know when the broad ligament had been tied in the way suggested by Dr. Macnaughton-Jones, if there was any dragging on the pelvic walls, and if there was a tendency for the uterus to become retroverted again?

MR. MANSELL MOULLIN said Dr. Maunsell's was merely a slight modification of Kelly's operation, the only difference being that the peritoneum was attached to the fundus of the uterus more completely and in a

circle round the summit, instead of to the posterior wall. In his own practice he generally performed ventral fixation. He was not prepared to say it was an ideal or a scientific method, but it seemed to him to answer the purpose, and had the further advantage that it was available in some cases where there was a slight descent also.

MR. BOWREMAN JESSETT did not see much difference between Dr. Maunsell's operation and that usually performed. The only difference seemed to be that a transverse incision of the peritoneum was made and the edges were sutured to the uterus; but was this an advantage? Personally, he preferred passing one or two long sutures through the fascia and peritoneum of the parietes, transfixing the posterior surface of the uterus just below the fundus. By this method the uterus was placed in a better position than when it was sutured through the anterior wall. In two cases where he had an opportunity of *post-mortem* examination some few years after the operation, he found numerous adhesions between the peritoneum and the uterus, the latter being quite mobile. With regard to uterine suspension, his experience was not so large as in uterine fixation, and until he saw good reason for altering his opinion, he would adhere to ventral fixation in preference to ventral suspension. The operation proposed by Dr. Macnaughton-Jones was ingenious, to say the least, but he thought further experience necessary before accepting it.

DR. ROUTH said Fellows should be told that one of the cases which was examined *post-mortem* had had a baby between the time of the operation and the death of the patient. He should like to know the state of the uterus of that woman in particular. It was reported that the operation had in no way interfered with labour.

DR. MAUNSELL, in reply, said he did not think his paper contained anything new. Several speakers had referred to the fact that there was no difference in his operation from those of others, but he would remind them that in such matters the profession proceeded slowly, and he brought forward his modification in the hope that it might be thought a little advance on some others. He considered that the Alexander operation was the ideal, but other operations were necessary sometimes where there were adhesions, or where a tube or some disease had been removed on one side. With regard to the operation described by Dr. Macnaughton-Jones of stitching up the ligaments on both sides, he tried something of the same kind before the operation detailed that evening. In that operation he sutured the round ligament and fundus of uterus to the abdominal wall on either side, making the fixation by means of the last suture. There was no *cul de sac* left if the sinus was brought together by sutures in the way he had described.

DR. MACNAUGHTON-JONES then read notes of a

CASE OF URETHRAL CYST,

which will be found under the heading of "Clinical Records" (page 109).

The PRESIDENT said it was interesting to hear that supra-pubic cystotomy had been performed for the recovery of the piece of catheter.

DR. MANSELL MOULLIN, referring to the operation for the removal of the catheter, said he would have operated in the same way. It was easy to operate from below, but the difficulty was, it did not readily heal. In a case of the kind he had to operate four times before succeeding in closing the wound.

DR. ROUTH said he had treated those cases by means of a hot iron. In the case narrated the swelling was at the lower part of the urethra. If it had been treated by a hot iron, the urethra would have contracted and the growth been destroyed. He had cured many in that way, and never thought of cutting away a portion of the urethra. It was astonishing what contraction a red-hot iron would bring about, not only in the growth but in the surrounding tissue.

MR. BOWREMAN JESSETT said he could confirm the

remarks which had fallen from Dr. Routh, although he preferred the galvano-cautery to the hot iron on account of the precision and ease with which it can be applied.

Dr. HEYWOOD SMITH said that surely the cases referred to by Dr. Mansell Moullin where there was difficulty in healing were not the same as cases of immediate operation, but applied to old-standing cases of vesico-vaginal fistula, when the edges had to be revived. Where the opening had to be made through the vaginal wall and immediately closed he did not think any difficulty in healing would be experienced.

Mr. MANSELL MOULLIN pointed out that the difficulty actually occurred in a case in which the incision was made for the extraction of a small stone.

Dr. MACNAUGHTON-JONES, in reply, said he did not operate from below because of the condition of the urethra approaching the neck of the bladder. In those cases he thought the clean supra-pubic cystotomy, especially where the finger had to be introduced and care taken not to break the glass catheter, was preferable to the vaginal method. It was as harmless a procedure as the other.

Mr. JESSETT brought forward a specimen of a tumour recently removed from a lady, *æt.* 65. She had a fibroid tumour for some years, which had never caused her any inconvenience. Then it suddenly began to grow, and when he saw her she had a tumour as large as a football in her abdomen, and attached to the uterus. He advised its removal, as he believed it was a soft myoma. The uterus was removed by the sub-peritoneal method. On cutting into the tissue a pint of fluid was let out, the uterine cavity was opened behind and found free from growth. The tumour was in front of the uterine wall. It was a cystic degeneration of the uterus. It was only removed a few days ago and had not been properly examined by the pathologists. The naked-eye appearance suggested it was somewhat akin to the case described by Dr. Maunsell. It was a rather uncommon condition in his experience, for a fibroid to become cystic at the age of 65.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

THE sixty-fourth Annual Meeting of this Association was held in the rooms of the Medical Society of London on July 20th and 21st, under the presidency, during the early part of the proceedings, of Dr. R. PERCY SMITH, and later of the new president, Dr. T. OUTTERSON WOOD.

In relinquishing the chair, Dr. PERCY SMITH moved a vote of thanks to the officers of the Association who had been associated with him, expressing his opinion that the Association was extremely well served in that respect, and particularly mentioned Dr. Robert Jones, the General Secretary, and Dr. Hayes Newington (treasurer).

Dr. CLAYE SHAW proposed, and Dr. WEATHERLY seconded, a vote of thanks to Dr. Percy Smith for his conduct of the business of the Association during the past year, which was carried, and Dr. SMITH replied.

Dr. T. OUTTERSON WOOD then took the chair, and read his

PRESIDENTIAL ADDRESS.

He first made sympathetic reference to the late Sir John Sibbald, and went on to show the progressive increase in the membership and usefulness of the Association, the members having risen in numbers from 394 in 1880 to 680 to-day. On the question of "absence on trial," which had recently been discussed, owing to the Commissioners having stated that it was illegal to bring a patient back to the institution from which he was granted leave of absence before the expiration of the time mentioned in the leave, the Association had obtained opinion that a patient could legally be brought back at any time, thus confirming the Association's reading of the Act. Dr. Wood next dealt with the dispensing of dangerous drugs, and referred to the ease with which patients could obtain them in

unlimited quantities by simply taking the prescription from one chemist to another. One patient by this means obtained 1,800 grains of hydrochlorate of cocaine in a 20 per cent. solution for the purpose of committing suicide. He also touched on incipient insanity, reminding members that in a discussion in 1896 he advocated that patients whose insanity was doubtful should be placed under care and treatment, away from home, on the application of a relative supported by a written medical opinion, to a magistrate for a judicial order empowering the detention of the patient for a specified time. He referred to the large numbers of people having no knowledge of the care of the insane who were advertising for insane patients, and to the fact that the friends frequently availed themselves of that means of ridding themselves of a troublesome burden. The result generally was the removal of the patient to improper care, and the loss of the valuable early period for treatment. He advocated the registration of places and persons taking mental cases, especially in regard to so-called "nursing homes;" and in his opinion the State registration of nurses should follow the registration of the persons who employed them in these homes. A large part of the address was concerned with the question of nursing. There were now 6,900 nurses possessing the certificate of the Medico-Psychological Association, probably the largest number in the nursing world holding certificates of uniform value from one constituted authority. Last year the period of training for that certificate was fixed at three years, thus freeing the Association's nurses from the taunt of being inadequately trained as compared with hospital-trained nurses, and it would greatly strengthen their claim for inclusion in any scheme of State registration. He deprecated applying the term "attendants" to male nurses in asylums, to whom the term "nurse" was as applicable as to females. Some advocated female nurses for male insane patients; some such cases as were physically ill might be suitably nursed by women, but the proportion could not be large. It must not be forgotten that competent male nurses were as much an absolute necessity in asylum life as in private practice, and he could not help feeling that they were often what doctors themselves made them. He was not quite sure that all the stir now being made about State registration would be of much material benefit to the nurses themselves, or whether perking them up with a glistening pride might not end in their wearing a crown of sorrow, but there was no reason why Medico-Psychological nurses should be made to appear outside the pale of official recognition. The public was well protected in the matter of nurses by the members of the medical profession, who took good care to employ such nurses as were properly trained, of good character and well recommended. He doubted if any scheme could improve upon the excellent system of the Royal British Nurses' Association, under the presidency of H.R.H. the Princess Christian. The Association was largely indebted to her Royal Highness for the interest she had taken in the status of asylum-trained nurses. Finally, he declared that psychological medicine was now more intimately associated with general medicine than formerly, and he trusted there would be continued endeavour to strengthen the bonds uniting them, and which would ere long bring them into one harmonious whole.

A hearty vote of thanks was accorded to Dr. Wood for his address, and the Association then discussed the following papers:—"The Employment of Female Nurses for the Care of Insane Men," by Dr. G. M. Robertson (Larbert, N.B.); "Some Points in the Early Treatment of Mental and Nervous Cases, with special Reference to the Poor," by Dr. Helen Boyle (late medical officer of Claybury Asylum); "The Provision of Suitable Accommodation for the Various Forms of Insanity," by Dr. Wilson Rhodes (member of the Lancashire Asylums Committee); "The David Lewis Colony for Epileptics, Alderley Edge," by Dr. Alan McDougall (Resident Medical Officer); and "Notes upon the Incidence of Tuberculosis in Asylums: a

Comparative Study," by Dr. George Greene (medical officer, Claybury Asylum).

On Thursday evening the annual dinner was held at the Whitehall Rooms, Hôtel Métropole.

CENTRAL MIDWIVES BOARD.
MEETING, JULY 27TH, 1905.

THE President, Dr. CHAMPNEYS, in the Chair.

AFTER the Minutes had been confirmed, the Secretaries read a letter from Dr. Wheatley, M.O.H. for Salop, with reference to a midwife who had in ignorance reported a case of puerperal fever as a slight ailment. It was agreed by the Board that the rules regarding such cases must be strictly conformed to and a medical man be called in, twice if necessary, to make a correct diagnosis.

Dr. Symons, M.O.H. Bath, wrote to ask who was to notify in the case of mother or child dying before the arrival of a medical man. He was referred to Rule E 18, which delegates such notification to the midwife.

The SECRETARY also read a letter from the Clerk of the Gloucester County Council enclosing a Report from the Sanitary Committee with reference to the carrying of appliances by midwives and the laying-out of the dead. It was shown that these appliances in the hands of those untrained in their use was more often a source of mischief than usefulness, and had often had serious results.

Miss PAGET proposed that "The Board would suggest that illiterate country midwives should be trained in the use of appliances by the local authorities," a motion which was carried, Sir Wm. SINCLAIR dissenting on the grounds that it was undignified to make a suggestion which could not be enforced.

Miss PAGET, with regard to the query *re* laying out the dead (expressly forbidden in the Rules), suggested a modification of the Rule in small villages where the midwife was often the only person to do it, and had very few cases to attend, but such suggestion was withdrawn when the PRESIDENT urged that in the first place they had no power from Parliament to dispense with the power of their Rules, and, secondly, such modification would open a very wide gap in the hedge for many midwives to evade a very important regulation.

The SECRETARY then read a letter from a German midwife holding high certificates from her own country, who asked for her Eng.L.O.S. oral examination to be made in German.

The PRESIDENT thought this might be done if, as in the Brussels M.D. examination an interpreter were paid by the candidate, but Sir Wm. SINCLAIR said it would be better, from an "undesirable alien" point of view, for her to wait until she knew the language better and an answer to that effect was returned.

The Report for the last examination showed 307 candidates and 225 successful candidates. The cost of examination had been £322 16s. 10d., almost covered by candidates' fees. Both Sir Wm. SINCLAIR and the PRESIDENT, as visitors, expressed their satisfaction with the class of women who had entered and the result of the oral examination; defects in the written one being often due to want of education rather than intelligence. Sir Wm. SINCLAIR added that the only great defect was evidence of unskilled teaching, some of the notions on obstetrics being obsolete. The PRESIDENT had also noticed three defects—(1) with regard to the feeding of infants on artificial food; (2) making an abdominal examination; (3) ignorance of the Rules governing their profession.

The proceedings terminated with the reading of the Report regarding cases heard *in camera* concerning misconduct and violation of Rules by certain midwives.

AN invitation to hold the annual meeting of the British Medical Association next year in Toronto, presented by Dr. Cameron, was cordially accepted by the General Meeting of the Association on Wednesday.

France:

[FROM OUR OWN CORRESPONDENT.]

PARIS, July 30th, 1905.

TREATMENT OF PARALYSIS AGITANS.

PARKINSON'S disease affects always a progressive form, which it is very difficult to arrest. Therapeutic action says Professor Grassel, is purely palliative as regards the principal symptoms of the malady. Electricity in the static form appeared to have had some beneficial effect on the rigidity and the palsy.

Warm baths are not always well borne, and where they are they bring about a certain *bien être*. Suspension has been tried and in some cases has given temporary relief.

To stimulate the general nutrition the arsenical treatment has given the best results, while the serum of Truneczek in hypodermic injections has procured a notable improvement. M. Alquier prefers giving it by the mouth.

Sulphate of potash, }
Sulphate of soda, } $\frac{1}{2}$ drachm;
Chloride of sodium, 6 drachms;
Phosphate of soda, 15 grs.;
Carbonate of soda, 20 grs.;
Water, 16 ozs.

A tablespoonful at the commencement of the two principal repasts, in a half a glass of water; continued twenty days per month.

Massage done with prudence improves the rigidity and the improvement continues for several months.

As to medical agents addressed to the symptoms, borate of soda has been recommended by Sacaze, given in 10 gr. doses three times a day. Notable remissions have been obtained by the salt, but it is not always well borne and provokes nausea and diarrhoea.

Hydrobromate of hyoscine in small doses (1-250th gr.) injected hypodermically, is a very efficient treatment but it sometimes produces vertigo and dizziness.

TREATMENT OF JAUNDICE.

The diagnosis of the cause of jaundice cannot be always made at the outset, but a general treatment can be always instituted and constituted, says Professor Huchard, by the milk diet and laxatives.

The milk diet is very important. Every four hours a large glass of milk with two or three table-spoonful of some alkaline water should be taken; it stimulates the biliary secretion and does not fatigue the stomach. Besides the milk, an infusion of boldo leaves might be given during the day and an occasional glass of Vittel water. The laxatives should belong to the saline series (sulphate of soda), while an enema of cold water (one quart) should be given morning and evening and retained ten minutes. The morning laxative (a teaspoonful of sulphate of soda in half a glass of Vichy water) may be suspended after eight days and replaced by benzoate of soda given in 15 gr. doses twice a day in a little Vittel water. At the end of another period of eight days, a pill of podophyllin may be given at night, while the *regime* of the patient may be a little relaxed. When the icterus lasts several weeks the attendant should advise a consultation so as not to bear alone the responsibility of a doubtful situation.

Pruritis is one of the complications of chronic icterus which commands special attention. Alkaline baths, the warm rain douche, lotions with a solution of coal-tar (a table-spoonful to a quart), ichthol (10 per cent.), &c., are some of the agents that relieve the itching. After the lotions the parts may be powdered with—

Talc powder, 4 ozs.;
Menthol, 12 grs.

If the pruritis persists, the body might be painted over twice or thrice daily with—

Ichthol, 3 drachms;
Spirit, } 2 ounces.
Ether, }

or
Glycerine, 2 ozs.;
Chloroform, 4 drachms.

Even in grave cases of icterus hope should not be abandoned.

M. Chaffard recommends the following treatment which has been successful in some cases. Two quarts of milk daily and every morning an evacuating enema followed in an hour by another enema of salt water (6 ozs. at 7-1,000). The nourishment consists in absorbing daily 3 ozs. of pig's liver, reduced to a state of pulp in a little water. The agitation is relieved by enveloping the patient morning and evening in a sheet steeped in warm water. Over the sheet is placed a blanket and the patient left in position three-quarters of an hour.

As long as the diuresis is kept up and the quantity of urea eliminated is a fair average, hope may be entertained; but where the urea falls to a drachm and a half, the prognosis is very unfavourable.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, July 30th, 1905.

AT the Free Society of Surgeons, Hr. E. Hollande^r introduced the subject of
THE SURGERY OF THE PANCREAS.

He saw a man, æt. 32, with endemic icterus, that had come on gradually and without pain. The cachexia was increasing, both œdema and dulness were present in the upper abdomen, and there was a palpable resistance. The abdomen was opened, and as was expected a cyst of the pancreas was found; this was filled with a biliary, greenish fluid in which a good deal of cholesterolin was present. A stone, embedded in the anterior wall, was removed. After the operation there were fatty stools, and a free secretion of bile from the wound. Both disappeared, and nothing remained but the pancreatic fistula, and this in its turn disappeared in about two months. The case was one of simple pancreatic cyst, through blocking with a stone. As regarded the character of the fluid, there was passage of bile into the pancreatic passages.

Hr. Korte was doubtful about such a passage, as the papilla was blocked by a stone and he rather thought that the contents of the cyst were coloured by the general jaundice. He had himself operated on a similar case a short time before, and on account of the high degree of stasis in the biliary system, he had performed cholecystenterostomy.

Hr. J. Israel spoke on the

DIAGNOSIS OF SUPRARENAL TUMOURS.

He spoke of the occasional difficulties of diagnosis in such cases, at least when no sign of Addison's disease was present. To distinguish this disease from renal tumour was difficult, for the reason that hæmaturia might be present in either, either because the suprarenal tumour had grown into the kidney, or from pressure by the tumour mass on the vena cava, thus setting up stasis in the kidney and blood in the urine.

The forms under which suprarenal tumours appeared were:—

(a) Simple metastases in various parts of the body, no primary tumours being discoverable.

(b) No tumour was to be felt, although hæmaturia, paroxysmal pain, paræsthesia in the region of the lumbar plexus, pointed, when no stone could be discovered, and there was loss of power, to malignant tumour of the kidney or suprarenal body. In favour of the former were the early appearance of pain in the region supplied by the lumbar plexus, and of fever.

(c) The tumour was entirely supra-renal, the kidney itself remaining quite normal.

(d) The kidney could be distinguished from the tumour by the fingers. By further growth it naturally could no longer be distinguished. Pains and feverish symptoms came on, and death might take place from uræmia from thrombosis of the inferior cava.

If there was a large tumour, no longer separable from the kidney, then it was often very difficult, even in a pathological preparation, to distinguish whether the kidney or the suprarenal body had been the starting point.

Hr. Neuhäuser spoke on

SOME UNKNOWN TYPES OF RENAL HYPER-NEPHROMATA.

He had examined a large number of kidney tumours out of Israel's collection, and amongst them some hyper-nephromata. These were tumours that had their origin in ruptured suprarenal germs, and were to be found in other places, but especially within the renal capsule or in the cortex of the suprarenal bodies. He had observed a distinct type in which the stroma of the tumour hypertrophied in a tumour-like manner and choked the other tumour elements.

At the Surgical Congress Hr. Weinrich spoke on
INTRA-VESICAL OPERATIONS AFTER NITZE'S METHOD.

He said that from 1894 to March of the present year he had observed 399 cases of tumour of the bladder. Of these 150 cases of papilloma were operated on intra-vesically by Nitze's method—that was by the aid of Nitze's operation cystoscope. On account of the free bleeding that made a view of the field of operation impossible, the operation had to be done repeatedly in every case. The bits of tumour cut off were readily washed away with the urine. If the bleeding was very profuse the sectio-alta and tamponade should be resorted to, but the bleeding had always ceased spontaneously. The advantages of the intra-vesical method were its slight degree of danger (only one death), no narcosis or long lying in bed (the patient could go about and the operation be performed in the consulting room, and he could follow his occupation). The cure was more radical than after the high operation, from which recurrences almost always took place, possibly through implantation. The actual recurrences in the 150 cases were 21, they were very amenable to renewed treatment, which was readily submitted to. In half the cases the papillomata were multiple.

GERMAN MEDICAL TOUR.

The fifth medical tour takes place this year from September 10th to the 23rd. The starting point is Munich, and the following places will be visited:—Gmunden, Ebensee, Ischl, Aussee, Salzburg, Reichenhall, Berchtesgaden, Hallein, Gastein, Innsbruck, Igls, Brennerbad, Gossensass, Levico, Roncegno, Arva, Riva, Gardone, Salo, Sirmione, Garda, Bozen-Gries, Meran. The whole journey, including railway, carriages, and steamers, free board, lodging (with the exception of wine), and a copy of the official report, costs only £12 10s. Any English medical men wishing to take part in this tour are requested to write to Hofrat Dr. Gilbert, Baden-Baden, Germany, who will at once send programme and the necessary cards. The last date for application is August 20th.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, July 29th, 1905.

HOW CAN NURSING BE PROMOTED?

At the Gesellschaft für Innere Medizin, Hamburger raised the all-important subject of the mother nursing her own child. Artificial feeding was always a dangerous proceeding, he said, and more particularly in hot weather. This looked like irony of the new apparatus of Swoboda, who had just sat down after spending half an hour on a description of the contrivance he had designed for the preparation of the infant's food at home. It is an elaborate instrument with heating and freezing arrangements. Hamburger, however, thought that mothers should make greater efforts to feed the infant with the natural apparatus rather than resort to artificial means on the flimsiest excuse given by a midwife. The profession, he assured us, was not free from blame in this respect, which certainly did not add to our credit. He contended that the midwife or medical adviser who encouraged such artificial feeding was responsible for the life of the child, and if the law were more careful in the investigation of this responsibility we would have a lower infantile mortality. It should be made penal for a midwife

to advise, and a report demanded of the medical attendant for such a serious step.

Hock admitted the truth of the rapid increase of hand-fed babies, and thought that midwives should be so impressed with their duties in this matter as to inform the mother that this was a serious drawback, and should always be eschewed.

Sternberg warned the meeting of another factor that should not be lost sight of in their condemnation, *viz.* insurance. A very good clause had been added to the operative department that no benefit could be claimed till six weeks after the confinement. This was a step in the right direction, but it did not go far enough. Yet Pfandler said the midwife was our greatest barrier for child protection. They were a kind of uneducated family adviser that did infinitely more harm than good. The only thing left for the medical profession was to institute a proper feeding propaganda. Bunge's publication was full of instruction, and his articles on alcoholism and nursing could not be disputed—the health of the mother is the best test of the milk.

Knapp thought that no less than 95 per cent. of the females confined could suckle their own child if they wished, but society was against this duty. The Berlin Town Council spent 90,000 marks on the laudable object of getting mothers to nurse their own babies. Could Vienna not follow this example with advantage?

Reither advocated better instruction for our midwives. They should pass a rigid examination in the feeding and general nursing of infants. The newly-born were the victims of ignorance in this so-called age of enlightenment.

INSUFFICIENTIA VALVULÆ TRICUSPIDALIS.

Reiter showed a case, *æt.* 45, with insufficiency of the tricuspid valve, not a relative condition, but a real organic lesion. The murmur was musical, located to the site of the tricuspid and occurring at every systole of the heart. Since February, 1903, the patient has been under observation with all the signs and symptoms of non-compensating disturbance. He asked the members to tell him what was the cause of the morbid change in this particular ostia. It must have been due to some myocarditis, to which no place in the clinical history can be assigned. The most common cause in these cases is articular rheumatism, which is quite absent. Even rheumatism would leave the case unique as the left side of the heart is usually attacked, and not the right. Bamberger gave it as his experience that only two cases of the tricuspid occurred in 250 cases; Huchard met with it more frequently—two in fifty. The patient had never suffered from any of the infantile diseases, such as diphtheria, scarlet fever, &c., when he was young, although he tells us he had measles when he was eighteen years of age, which does not usually leave any cardiac lesion. In 1898 when the patient was thirty-nine years of age, we hear of him having inflammation of the lungs. Even this gives us no clue to myocarditis, and the present vitium. Gonorrhoea and epididymitis left no bad effects. The symptoms of the patient when first received into hospital were palpitation, difficulty of breathing, and swelling of both legs, which first commenced in 1902. The objective changes in the heart must have originated somewhere about 1898 and 1902, or between thirty-nine and forty-three years of age.

Whether the pneumonia left an ulcerated endocarditis we have no reliable testimony or symptoms to fall back upon, although it might be a suggestive etiology. The patient acquired syphilis in 1903, when he was thirty-four years of age, and was treated with thirty-four inunctions. Here we have a clinical picture of the cardiac lesion occurring five or nine years after the supposed infection, and attacking the right side of the heart alone, approaching with arrhythmia, such as bradycardia, reducing the heart to thirty beats for weeks at a time associated with difficulty of breathing, and finally pains in the long bones and the presence of cutaneous gumma. The common cardiac remedies for toning the heart, such as digitalis, strophanthus, caffeine, &c., were administered with out relief, while

energetic antisymphilitic medicines gave distinct subjective relief, and greatly modified the arrhythmia.

Operating Theatres.

KING'S COLLEGE HOSPITAL.

ABSCESS OF THE LUNG.—MR. PEYTON BEALE operated on a man *æt.* about 43, who had been under the care of Dr. Dalton, and was suffering from an abscess in the lower part of the left lung. His history was not easy to obtain as he was an Austrian, but it appeared that some time ago he had gastric symptoms which rather pointed to the presence of a gastric ulcer. Recently, however, he had suffered from an affection of the lung, and had for a week or two been expectorating small quantities of very foetid pus. As this continued, and as the patient was steadily losing ground, Dr. Dalton considered it desirable that the abscess in the lung should be drained. On the left chest below the angle of the scapula, there was a small area of absolute dulness and a certain amount of impairment of resonance extending around it for some distance. The following operation was performed:—The rib in the centre of the area of dulness was exposed, the periosteum loosened from it for a distance of two inches and that portion of rib was removed. An incision was then made and a fairly large quantity of very foetid pus at once escaped from a cavity in the lung which might be estimated at about the size of a tangerine orange, but which was very irregular in shape. On exploring the cavity with the finger its limits in every direction were easily defined, and no sinus or passage could be detected extending upwards, downwards, or inwards. At the centre of the incision the layers of visceral and parietal pleura were obviously in contact, but only for about one inch; above and below this the incision had opened the pleural cavity, from which there escaped a quantity of clear fluid estimated at about ten ounces. On examining the pleural cavity with the finger, it was found to be obliterated in the form of a band reaching inwards to the vertebral column. The abscess cavity in the lung was as far as practicable shut off by sutures from the pleural cavity and packed with gauze plugs. Mr Beale said that this was evidently an abscess of the lung, the infective source of which must have been towards the vertebral column; such infection had probably spread up close to one of the crura of the diaphragm, and so reached the root of the lung, and travelled outwards. The source of infection might have been a gastric ulcer situated on the lesser curve of the stomach, and around which adhesions had formed before it had ruptured. Another possibility was an acute pancreatitis which by the formation of adhesions had been prevented from infecting the peritoneal cavity. Another possibility, he pointed out, was a spinal cavity, though in the case he had just operated on there were no symptoms suggesting this. A sub-diaphragmatic abscess, he remarked, might be formed in connection with an abscess of the liver, or following an acute suppurative appendicitis; in the latter case it was very common indeed, he said, to find the pus travelling upwards, following the ascending colon, and sometimes reaching as far as the splenic flexure. In the case just operated on the difficulty of obtaining any reliable history from the patient made it, he thought, impossible to say which of all these conditions had caused the lung abscess, but the probability was that

an old gastric ulcer was the initial source of the trouble. The patient's condition at time of operation, he said, was distinctly critical, and such as to preclude any real attempt at ascertaining the source of infection.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5 0s. 0d.; Half Page, £2 10s. 0d.; Quarter Page, £1 5s. 0d.; One-eighth, 12s. 6d. Considerable Reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the Publisher.

Small announcements of Practices, Assistances, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and Colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, AUGUST 2, 1905.

THE PRACTICAL ISSUES OF MEDICINE.

AMONG many interesting addresses delivered at the Leicester meeting of the British Medical Association, that of Dr. Maudsley was not the least attractive. As a matter of fact his discourse was of the philosophical nature that illumines the path ahead hardly less than that which we are actually traversing or have already left behind. The field opened up by scientific investigation has become so extensive and at the same time so specialised that medical men, both collectively and individually, are somewhat apt to lose sight of the practical issues which furnish incentives to the generalisations that form the basis of our labours as a learned profession. It is well, therefore, now and then to pause and take a calm survey of the situation not only in regard to the present, but also to the past and the future. The doctrine that prevention is better than cure is as old as the hills, but it nevertheless forms as strong and unerring a guide to the pathologist of the twentieth century as it did to the mediæval philosopher; or, for that matter, to reasoning mankind in any of his early or prehistoric stages. Yet that lesson, elementary and self-evident as it may seem, has yet to be learnt by the world at large, so far as the administrative side of public health is concerned. In many local authorities, urban as well as rural, the question of cost is allowed to stop the wheels of progress with the result that the community have to pay an enormous indirect taxation in sickness and death, due to preventable disease. The standing reproach of an excessive infantile death-rate is ever with us. The evil might be to a great extent removed by the installation of municipal supplies of pure milk

in our great towns. Before the end of the present century it is probable that the physique of the nation will be carefully fostered in that way as an item of ordinary natural expenditure. The money thrown away in the recent war in South Africa, for instance, would have become an invaluable national asset had it been expended in the installation of municipal milk supplies for the poor of large towns of the United Kingdom. Dr. Maudsley dwelt pointedly upon the enormous saving of human life that had resulted from the increased attention paid to zymotic diseases within the last few generations. At the same time he wisely insisted that in the sphere of beneficent activity the physician had more worlds to conquer before he would be entitled to rest and be thankful. The splendid triumphs already attained are to be regarded merely as pledges of victories that still lie hidden in the womb of futurity. After all said and done, however, we find ourselves falling back upon the gospel of prosaic simplicity preached by the pioneers of public health. Pure air, pure water, pure food, with wholesome environment and sensible living, represent the beacon-lights of the sanitarian. In discussing the prevention of consumption, Dr. Maudsley touched upon various points of essential importance to the public. His approval of sanatoria for the treatment of sufferers from that disease is carefully qualified. But while he insists that isolation and special treatment offer no royal road to the stamping out of human tuberculosis, he nevertheless brings into prominence another crucial feature of the situation. Are we not too prone, he asks, to disregard the predisposing influences of heredity? There can be little question that in our joy at finding out the curability of a certain percentage of cases of lung consumption, we have more or less forgotten the medical experience garnered by our forefathers of a pre-bacterial age. It is well, therefore, to be reminded, with curt directness of phrase, that so long as consumptives become fathers and mothers it seems hopeless to expect to cut off the entail of this terrible scourge. This observation opens up moral issues of the widest and gravest character. How can any responsible human being consider himself entitled to bring into the world children who will be exposed to the curse of Cain in the form of some disabling malady, such as syphilis, tuberculosis, or insanity? Shall we adopt Dr. Rentoul's suggestion and sterilise the insane, the tuberculous, and other degenerates? Whatever decision may be arrived at ultimately by society as to this moot point, one may surmise that the general tendency will be to place increased restrictions upon undesirable marriages of the kind indicated. So far as lunatics are concerned, we have them under more or less control, and it would be comparatively easy to prevent their reproduction. As things stand, the way in which insane persons are periodically released from asylums and permitted to procreate fresh potential lunatics is

simply a scandal. Although on the whole the tone of the address under notice was somewhat pessimistic, it nevertheless held beneath the surface a firm and reassuring hold upon the principles that must infallibly maintain the onward and upward progress of mankind as the dominant factor in the world's evolution.

PERNICIOUS ANÆMIA.

THERE are few subjects in medicine which have aroused more discussion regarding etiology and pathology than pernicious anæmia, and there is certainly no well-recognised clinical entity whose pathology is still so much a matter of speculation. In the classical description of the disease given by Addison exactly fifty years ago, he remarks: "On examining the bodies of such patients after death, I have failed to discover any organic lesion that could properly or reasonably be assigned as an adequate cause of such serious consequences." It can hardly be claimed that on this point we have got much beyond Addison, although it is true that a fairly definite pathological anatomy has now come to be connected with pernicious anæmia. The most noticeable feature of this anatomy is the change in the bone marrow, first noted by Cohnheim in 1876, and it is consequently in the bone marrow that many observers from his time down to the present have sought the essential lesion of the disease. The change in the marrow, which has been described as a reversion to embryonic type, consists in a diminution in number of the erythrocytes and normoblasts, and a comparative increase of cells of megaloblastic type. It is not necessary to assume, however, that this condition is the primary lesion, as will presently be seen. Other observers see in pernicious anæmia a resemblance to certain toxic states, though as to the origin of the assumed toxin there is the greatest difference of opinion. Hunter holds very strongly that the toxin is the result of a septic condition of some part of the alimentary canal—mouth, stomach, or intestine—and he has discovered deep-seated inflammatory changes of the alimentary system in many cases of the disease. His theory is, in fact, that pernicious anæmia is a chronic infection of the alimentary canal, the changes in the blood and marrow being only symptoms of severe disturbance thence arising. Whether one agrees with Hunter or not in his view of the origin of the toxin, there are strong arguments in favour of the view that the changes of the blood in pernicious anæmia are due to the circulation of a toxin, however derived, which has a special action on the red blood corpuscles. It is fair to assume that given such a toxin as would have special action on the red blood corpuscles, whether in the circulation or in the marrow, it would have similar action on cells in the immediately precedent stage, namely, the normoblasts, and would consequently produce the typical condition found in the marrow. In certain experiments (a) recently

conducted by Bunting, a condition of the blood and bone marrow closely resembling that of pernicious anæmia was produced by injection of animals with ricin. While nothing can yet be said to be proved regarding the pathology, as distinct from the morbid anatomy, of pernicious anæmia, yet it is not too much to say that the toxin theory is at once the most promising and the most comprehensive.

A JUDGE ON CRIMINAL INSANITY.

THERE is no part of our English jurisprudence less satisfactory than the legal view of mental responsibility and irresponsibility. The whole matter demands impartial investigation and the formulation of fixed scientific principles for the guidance of our judicial system. Under existing circumstances the plea of mental irresponsibility, if raised on a prisoner's behalf, is disposed of on grounds that often appear to be irrational, groundless and unscientific. In the case of the Birmingham lawyer, Edalji, who was sent to penal servitude a year or two ago for the mutilation of cattle, we pointed out that if he were really guilty of such a purposeless act he must have been insane, and that to send him to prison instead of to a lunatic asylum was simply to perpetuate a violation of British justice. A petition to that effect was presented to the Home Secretary, the Right Hon. Aretas Akers-Douglas, but it elicited no satisfactory answer. Inasmuch as the petition in question was signed by a great many medical men, including some of the most distinguished authorities on mental alienation in the Kingdom, we consider that a courteous and fully reasoned reply should have been forthcoming from the Home Office, no less on the score of courtesy than on the desirability of defending the British law against any breath of suspicion of unsoundness. The Home Secretary, however, Mr. Aretas Akers-Douglas, is in no sense a politician of strong and impartial character. In various recent cases where the police system has been grossly at fault in the imprisonment of innocent persons, his chief desire appeared to be to excuse his subordinates. Doubtless the Home Secretary has obtained expert advice upon the point of the insanity or otherwise of the unfortunate lawyer convicted in the Great Wyrley cattle-maiming case. The public, however, no less than the medical profession, is entitled to know upon what scientific grounds the decision has been made to regard the prisoner as a sane man. Possibly, as the prisoner in that case was convicted upon purely circumstantial evidence, and as another man in the neighbourhood has since been convicted of a similar offence, Mr. Akers-Douglas has good reasons of his own for not re-opening the case. Anyway, we regard the imprisonment of that man without full and public statement by a skilled impartial commission as to his state of mind as a grave judicial scandal. Last week another exhibition of legal prejudice was given in the Central Criminal Court. The judge, Mr. Justice Ridley, had

(a) "Johns Hopkins Hospital Bulletin," June, 1905.

apparently made up his mind beforehand as to the absolute sanity of the prisoner Devereux, who was accused of the wilful murder of his wife and children. It appears that the defence secured by some means an examination of the prisoner by a medical man, Dr. Forbes Winslow. An account of his visits subsequently appeared in the newspapers, and the witness in question admitted that he had communicated the results to persons who had "spoken" to him. Conduct of that kind, assuming it to be as stated, is no less unworthy of the honourable traditions of the medical profession than obviously contemptuous of the jurisdiction of the Court. For all that, we see no reason why the judge should discourage witnesses coming forward with evidence as to the mental condition of the accused. A clergyman, for instance, testified to having known the Devereux family for years. He considered the prisoner to be deficient in intellect, and on one occasion the accused had posed as an American millionaire. Mr. Justice Ridley, however, turned into ridicule this evidence, which will appear to most medical men to be pertinent enough. The plea of unsoundness of mind was not advanced in this case, and therefore the Court was entitled, by this strict letter of procedure, to exclude evidence bearing on that point. At the same time it was shown that the grandfather, father and aunt of the prisoner attempted suicide, but the judge roused the laughter of his Court by asking whether anything was known of his great-great-grandfather. In addition to the foregoing relatives an uncle had been certified insane. We venture to suggest that these facts, coupled with the unusual circumstances of the crime for which the prisoner was on trial, suggested an adequate skilled examination of his mental condition. Instead of that the learned judge refused to call Dr. Scott, the medical officer of the gaol, to give evidence as to the prisoner's state of mind. We venture to submit that the whole incident presents in the strongest possible way the absolutely dogmatic, uninformed, and dangerous legal attitudes in dealing with questions involving soundness of mind. There will be no real security for the public in this important detail of administrative justice until the services of an impartial body of expert investigators are at the disposal of our judicial system. First let us have a Royal Commission of Inquiry as to the working of the present method of expert advocacy paid for by opposing parties in legal investigations and prosecutions.

Notes on Current Topics.

Central Midwives Board.

THE last meeting of the Central Midwives Board we are glad to learn, showed some slight improvement in the administration of business. The mass of comparatively trifling business with which the time of the meeting has hitherto been consumed was considerably reduced after a protest from the medical members. An opportunity was thereby

afforded for the discussion of matters of more vital importance. There is still plenty of room for improvement in the organisation of the Board. We suggest to Dr. Champneys, if he be unacquainted with the ordinary conduct of the business of a great central body of this kind over which he presides, that he should call in skilled advice upon the point. The protests of Sir William Sinclair and of Dr. Ward Cousins have been constant and emphatic, but appear to have been for the most part systematically ignored. It is simply farcical to suppose that men of their standing and experience should be brought up to London to discuss trifling details that might be perfectly well relegated to a sub-committee with powers to act or to report as might be deemed advisable. There is another side of the question. The two gentlemen named enjoy the respect and confidence of the medical profession, an approval which Dr. Champneys appears to regard with indifference. We shall be interested to learn his attitude with regard to the proposal of a lay member at the last meeting that midwives should be instructed in the use of "appliances"—meaning thereby, it is to be presumed, such articles as catheters, midwifery forceps, vaginal specula, uterine catheters, and so on!

Vital Statistics of London.

THE Registrar-General's returns for 1904, commented on by Dr. George Newman in the July number of the *Practitioner*, give very interesting information as to the incidence of certain diseases on the inhabitants of London. London has for years been famous as a healthy city, and it is satisfactory to find that the death-rate in 1904—16.6 per 1,000—was, with the single exception of the previous year, the lowest on record. One obtains some idea of the meaning of this figure when it is remembered that the death-rates of New York, Moscow, and Dublin, are 22.6, 27.6, and 25.2 per 1,000 respectively, while the death-rate for the whole of Ireland, with a population just less than that of London, is 17.5 per 1,000. In London, as might be expected, the highest rates are found in the central districts, and very low rates indeed round the circumference. Comparing the mortality of particular diseases to-day with that of twenty years ago in London, it is gratifying to find that in the case of all the acute infectious diseases there is marked improvement. This is noticeably so in the case of small-pox, scarlatina, diphtheria, and typhoid fever, and to less extent in the case of measles and whooping-cough. In the case of epidemic diarrhoea and of tuberculosis there is no improvement. The last-mentioned disease, followed closely by malignant disease, nervous diseases, and diseases of the heart and pneumonia, none of which show any marked improvement, contributes most largely to the death-rate. It is not a matter of self-congratulation, however, that the marriage-rate and birth-rate tend to move parallel with the death-rate, and

last year both of them reached their lowest point since 1855. That the birth-rate is not entirely influenced by economic causes is shown by the fact that the decline is greatest in the most wealthy districts, such as Hampstead and Kensington, and least in such places as Poplar and Stepney.

Dangers of Cold Storage.

NOWADAYS, when cold storage of food has become almost a necessity of civilised life in large cities, it is well that medical men should be conversant with the dangers arising therefrom. It is commonly recognised, of course, that meats which have been frozen are likely on removal from ice to undergo more rapid decomposition than would fresh meat. The changes of temperature involved in freezing and thawing apparently cause such changes in flesh as to render it more readily a prey to the bacteria of putrefaction. In the case of some meats, however, the change takes place much more rapidly than in the case of others, and everyone is aware that fish, game, and poultry, removed from cold storage, "go bad" more quickly than carcasses of beef or mutton. Apart from other points of difference, such as the quality of the meat itself, this is due in the main to the fact that the carcasses of beef and mutton are eviscerated before being placed in the cold chamber, while the bodies of fish and game are often placed therein whole. The result is that within a few minutes after removal, the entire body may be soaked with toxins, and ingestion of food in such a condition may cause very serious poisoning. It is unfortunate that it is so frequently the custom of the trade to stock fish and game whole, as if eviscerated immediately after being killed they would keep for a much longer period.

Tobacco and Health.

IN spite of the impressive series of conditions of disease treated of by the writers in the symposium on "The Effects of Tobacco in Health and Disease," in the July number of the *Practitioner*, we do not think many lovers of tobacco will be disturbed in their habits by the views there set forth. There is, indeed, on the part of most of the writers, a latent sympathy with the "vice" which seems to proclaim them as lovers of the weed themselves. It is true that they point out the evils of smoking by certain subjects in certain conditions, but the condemnation is somewhat formal and impersonal. Thus, as all the writers are, we believe, full grown adults, we are not surprised to learn that "there is a general consensus of opinion that it [smoking] is very distinctly harmful to growing lads." In adults, however "it will stimulate the brain to increased activity, and it will also produce a soothing effect in conditions of excitement." It would almost be possible from a study of the opinions of the different contributors to discover to what form of the weed each is addicted. There is no doubt that Sir Lauder Brunton smokes cigars for he

condemns both pipe and cigarette. In this opinion he is at one with Mr. Lambert Lack, who has a particular dislike—professional, of course—for Egyptian cigarettes, but we fear there is a conspiracy against the use of cigarettes, since no one has a good word for them. Indeed, the only satisfaction the cigarette-smoker can take to himself is indirect, when he learns that to a clay pipe is due a series of morbid conditions of the mouth culminating in epithelioma. It is perhaps just as well that the writers, being possessed of a just sense of proportion, have not in these pronouncements taken themselves too seriously, for assuredly no lover of tobacco will be terrorised from his source of pleasure by academic statements of the dangers to which he is exposing himself.

Common Salt as a Poison.

WE are certainly not accustomed to regard common salt as a poison, but rather as one of the most innocuous of chemical bodies. Itself a necessary of human life, its solution is commonly employed as the physiological substitute for the natural juice of the body. That, however, in large quantities it may prove a drug of serious power is shown by a case recently reported by Dr. Charles Combs. (a) By some misunderstanding, to a woman, aged thirty-five, after an operation for removal of an ovary, 500 cubic centimetres of a concentrated saline solution were injected instead of normal solution. In all, she received subcutaneously about a quarter of a pound of sodium chloride. The patient shortly became comatose, and after six hours of coma, passed into a state of mania. The pulse became too frequent for counting, and the respirations went up to seventy in the minute. There was insatiable thirst and constant vomiting and death occurred in twenty-four hours. Examination of the blood showed that the red corpuscles were much shrunken and crenated from osmosis and there is little doubt that death was due to oxygen-starvation due to complete loss of function of the red blood corpuscles.

Facilis Descensus.

MR. EUSTACE MILES has long been known as a faddist on such subjects as diet and training, and as faddists have to be suffered gladly in a modern community he has hitherto been met with the chaff that seemed suitable to the occasion. The principle of answering a fool according to his folly does not seem to have had the effect of showing people the threadbare absurdity of classical coaches from Cambridge abandoning the literature of the ancients for the practical application of modern theories of physiology and pathology. We notice in the columns of the daily press certain flaring advertisements in which sufferers from various ills are invited to consult Mr. Miles by correspondence, so we conclude that the cobbler has decided definitely to abandon his last, and to join the ranks of let us say, the unqualified practitioners. Whether Mr. Miles has placed himself in the hands

(a) *American Med.*, April 22nd, 1905.

of the "advertising staff" of the *Times* or in those of some other enterprising agents, he has certainly succeeded in producing announcements which for hyperbolic statement and bad taste it would be hard to beat. To every reader he "sends the message of health." If the health of any member of the family is not satisfactory, let Mr. Miles have particulars. Mr. Miles' experience and individual attention are at the sender's disposal. Mr. Miles is every day treating successfully obstinate cases which (in leaded type) have defied other treatments for years, and makes all the other magniloquent pretensions we are accustomed to in the most unabashed quack announcements. As part of his stock-in-trade Mr. Miles displays to the public the academical distinction of M.A.Camb., after his name—a fact which it may be hoped will at least lead to remonstrance from the authorities of the venerable college from which he graduated. If after dallying with the "unclean thing" for *nemo repente fuit turpissimus*, Mr. Miles has decided to go the whole hog, he need not involve in his career the University where at least he might have learned better things. It is not unlikely that the University and other important bodies may have something further to say upon the matter.

The Meat of the Poor.

THE British working man is, in spite of all temptations, a meat eater, and while he is prepared to pay for his beef and mutton, it is as well that he should be supplied with honest joints. Some food reformers may wish to see him subsist on cabbages and patent foods, but so far he has thriven well on meat, and there is no reason why he should not continue to do so. In Germany and France horse-flesh, because of its cheapness, is eagerly bought by the poor, and there is no particular reason why such meat should not provide sufficient nourishment for its consumers, even though it lacks the delicacy and tenderness of cow and sheep flesh. In Berlin and its suburbs there are no less than two hundred and fifty horse slaughter-houses, and even in good restaurants it is asserted that dainty "kick-shaws" not infrequently are manufactured out of horse-flesh. Certainly there can be no doubt of the origin of the meat in many German sausages, for in Hamburg, one of the centres of the trade, 5,000 horses are killed for food each year. In the East End of London, however, Dr. Thomas, the medical officer of health for Stepney, has unearthed a scandal which may well engage the attention of sanitary committees. It appears that the cat-meat vendors, who deal in the most undesirable parts of animals, are not confined to catering for the tastes of their feline customers, but may, and often do, prepare and sell meat for human consumption side by side with that pertaining to their legitimate occupation. Diseased meat is often sold for cats, and if these dealers are caught with such meat on their premises, they always excuse themselves by saying that it is not intended for man. On the other hand, Dr. Thomas points out

the temptation that undoubtedly exists to work up such meat into brawn and other such preparations, and he concludes that it is desirable that the two trades should be definitely severed from each other.

Nurses and Their Critics.

"AN OUTSIDER," who contributed an article on nursing to one of the nursing papers some week back, (a) can hardly have been surprised when she (we suppose it is "she") found a hornet's nest about her ears. The article was, indeed, a scathing criticism on the narrowness of outlook and character of the average nurse, a narrowness for which the conditions of hospital and nursing life are held responsible. There is no doubt, of course, that the life of a nurse is extremely exacting, and requires perhaps more than any other occupation for women, the sinking of one's own tastes and wishes. A nurse, more than most working women, lives in the midst of her work, and has, except in her brief annual leave, but little chance of getting away from it. It must not, however, be too hastily argued from this that an unusual narrowness of character must result. While it is true that complete concentration on any one occupation has a narrowing effect, it must not be forgotten that this effect is likely to be less in the case of nursing than in the case of most other occupations. A nurse's work is in truth a liberal education. She is brought into contact with more varied phases of human life and conduct than perhaps any one else, not even excepting the physician and the priest, and she must be dull indeed if her experience has not a broadening effect on her own outlook. It is no wonder that many nurses have indignantly repelled the rather superior criticisms of "An Outsider."

Lest We Forget.

THE lawyer is said to envy the doctor in that whereas his own mistakes are dissected with minute care in open court, the doctor's bad work is soon hidden by mother earth. This joke we are thankful to think, is more of a verbal pleasantry than a solemn accusation, and the lawyer's mistakes at any rate do not have such momentous consequences—attached to them as do the doctor's. Moreover, if a doctor be ever caught tripping, there are generally plenty of friends to keep the act fresh in the memory, even if the coroner's court did not exist for the purpose. Fortunately in England the medical man is spared the opprobrious rite of being expected to hang a lamp at his front door for every patient who dies under his care, as is the unhappy lot of the practitioners in "far Cathay." Even if the number of deaths has not to be recorded for public comment, the doctor has to suffer in other, and in some ways, less desirable, manners from reflections which he is unable to meet in open conflict. In Pennsylvania, where we suspect the law of libel must be very lax, a resident has

(a) *Nursing Times*, July 16, 1905.

recently taken a course of action to which over here we fancy there is no parallel. He has erected a monument in imperishable granite over the grave of his wife, on one side of which is carved the usual description of the deceased and a tribute to her virtues, and on the other, the following inscription—

“A victim of Chloroform Poisoning and Shock,
The result of a Doctor's Negligence.”

It would certainly add to the terrors of practice if the relatives of each patient who died were in the habit of carving on the tombstone their candid opinion of the doctor's treatment in the final illness, and it is to be hoped that the custom, if it become at all general, will be confined to the other side of the Atlantic.

Mr. Coroner Troutbeck and the British Medical Association.

MR. CORONER TROUTBECK, who has so successfully roused the dormant energies of the medical profession, seems to have friends in high quarters. At any rate, that inference appears to be supported by the fact that the representatives of the British Medical Association have been simply ignored by the Prime Minister. Accordingly, it is not altogether a matter of surprise that the representatives at the Leicester meeting last week passed a vote protesting indignantly against Mr. Balfour's omission to reply to the communications of the Association. The letter dealt with the refusal of the Lord Chancellor to pronounce judgment on the charges against the Coroner for South West London. At such a time, when the Government is receiving many kicks and few halfpence it seems a pity that the Prime Minister should fail to conciliate so powerful a body as the medical profession. Possibly his estimate of the weight of medical men as a political influence is based on former experiences of their want of unity and backbone. It remains to be seen whether Mr. Troutbeck's arrogance and insolence have roused a sterner spirit in the profession. It is intolerable that the Lord Chancellor should be permitted to play into the hands of a wilful Coroner by failure to discharge the duties appertaining to the woolsack, for which the nation, including the medical men, pay an extravagant salary.

Blackmailing Charge Against a Sanitary Inspector.

THE future of public health administration must obviously depend to a great extent upon its popularity, and the latter upon its purity. It is therefore of the utmost importance to exercise a constant vigilance upon the proceedings of local sanitary authorities. In London an exposure of wholesale official corruption recently took place in Holborn, and it is to be regretted that one of the most influential offenders was allowed to go scot free by a vote of the Borough Council. In another district, Marylebone, a grave charge has been made against a sanitary inspector. A builder in the neighbourhood alleges that between the

years 1898 and 1900 the inspector received from him blackmail to the extent of £240 upon eleven orders amounting to £905. The Sanitary Inspector has been suspended pending further action by the Local Government Board. It is obvious that abundant opportunity for rascality is afforded to sanitary officials by virtue of their position. If common rumour is to be believed a great deal of this kind of abuse exists in various parts of the United Kingdom. Clearly the dishonest inspector has merely to condemn drains and other parts of a house and blackmail either the owner or more conveniently the builder whom he recommends to the householder. Offences of this kind deserve rigorous punishment, for they strike a coward's blow at the health of the nation.

Resuscitation from Chloroform Poisoning.

CHLOROFORM with its disadvantages still continues an indispensable adjunct to the anæsthetist's resources, and were it possible entirely to eliminate the risk of syncope and respiratory failure during its administration there can be no doubt that it would supersede ether from the position that the latter now holds in the practice of many. But it may be taken as certain that while sudden deaths continue to occur in the hands of the most experienced anæsthetists, there is a proportion of cases in which no blame of any kind can be attributed to the administrator. The methods of resuscitation from chloroform poisoning are at best untrustworthy, and it may, therefore, be of interest to note a series of experiments by Dr. Joseph Winter on the applicability of suprarenal extract under such circumstances. Suprarenin, as is known, powerfully raises the blood pressure, and as the first symptom in chloroform poisoning is a fall in blood-pressure, it would seem eminently reasonable to try the effects of suprarenin under such circumstances. Dr. Winter began his experiments by isolating a mammalian heart and running 1-1,000 chloroform solution through the coronary arteries till the heart ceased to beat. It was then found that by replacing the chloroform solution by one of suprarenin of the same strength, active contractions were again set up. Cats chloroformed until heart and respiration had ceased were brought round by injecting suprarenin solution into the left ventricle, after other methods had failed to revive them. Intravenous injection was found to be without effect. Dr. Winter suggests that in cases where the ordinary methods of restoration from chloroform narcosis have failed, solutions of suprarenin should be injected into the left heart, and artificial respiration begun. The plan seems well worthy of trial.

Backache Remedies.

ONE of the most common symptoms complained of by suffering humanity is backache “Sacralgia” it is often termed, when the real cause of the symptomatic condition is perhaps not quite accurately determined, and this word carries with

it a vague sense of scientific propriety, comfortable alike to the physician and the patient. Women are greater sufferers than men in this respect, probably because in them constipation is more frequent, and the presence of a loaded sigmoid flexure is commonly productive of backache in nine cases out of ten. Muscular rheumatism so-called, is another mask worn by the same complaint, though this condition may be caused by physical over-exertion or prolonged muscular strain. Certain phases of the gouty state are also characterised by severe paroxysmal pain in the lumbar and sacral regions. This is the variety which yields so promptly to alkaline treatment. Then there is the backache of renal troubles, with or without associated lithiasis. A considerable fraction of cases is left over in which there is no discoverable cause. The pain is definitely lumbar or sacral, and it really does incapacitate the sufferer from following his or her occupation. These are the cases that are lured by the seductive offers held out by much-advertised quack remedies, offers that promise instant relief and permanent freedom from pain. It is all so simple—merely the consumption of a “specially prepared” pill, alleged to be drawn from “purely natural sources,” with, of course, the sanction of science thrown in, after which future bliss is certain! The removal of long-retained fæces will do much to take away the dragging pain which is such a feature of this condition, but the necessity for a more or less continuous use is one of the drawbacks of the vegetable purgatives. A timely visit to a gynæcologist will clear up many an obscure backache as will also a rectal examination, neither of which procedures should be neglected in those cases which do not speedily yield to the ordinary methods of treatment.

Bathing Fatalities.

Now that the bathing season is in full swing, every day brings with it a crop of fatalities from drowning, and though a good deal has been done at the frequented watering-places to prevent such accidents, it is doubtful if the full necessities of an efficient organisation are grasped. From some elaborate observations of Margulies, recorded in the *Berlin Klinische Wochenschrift* for June 19th, we learn that the act of drowning comprises five successive stages. First, that of surprise, which lasts 5 to 16 seconds and is characterised by gasping respiration. Following this is the second stage, during which respiration is in abeyance for about a minute. This is followed in turn by the third when deep respirations are taken—and water is swallowed. After continuing for from 60 to 150 seconds the fourth stage is reached, in which consciousness is lost and respiration ceases. This fourth stage lasts about one minute—and is followed by the final one during which for 30 to 50 seconds irregular gasping respirations are made. Taking, then, the longest time for each stage, we

find that the whole process of drowning is completed in five and a half minutes, and under some circumstances it may be much less. Margulies considers that the prospects of recovery are good if the subject be rescued during the first minute, fair during the second, and less and less favourable in the succeeding stages. Now as accidents to bathers almost always take place suddenly, it is obvious that a rescue service, if it is to be of any value, must be always on the alert and ready to proceed at a rapid pace to the scene of an accident; moreover, that its *personnel* should be comprised of several good swimmers and divers, who have been well trained in the methods of rescue. The usual old man in a boat who paddles about some distance from the shore is the merest salve to the consciences of those responsible for the safety of bathers, and the sooner he is superseded the better.

The Joy of Living.

THE mere sense of existence is a pleasurable thing to a healthy individual. The young man rejoices in his strength, for has he not that buoyancy of spirit and suppleness of limb which are the natural accompaniments of “good form” of brain and muscles? This physical sensation of *bien-être* is always enhanced by conditions of high atmospheric pressure and by increased brightness in the world around us. In other words, it is a question of the degree of aeration or oxygenation of the blood. The benefits derived from a so-called change of air are chiefly attributable to a diminution of those impurities, gaseous and suspended, found in the atmosphere of towns, and to the presence of a small amount of oxygen in the nascent state. Tales in which the scenes are laid upon parts of the earth's surface where the air is not up to the normal standard, or upon lunar territory, are still popular among a certain class of readers. Various speculations have been made, from time to time, as to the effects which would be produced upon the human race by wholesale modifications in the composition of the atmosphere. The latest fancy of this sort emanates from a new Parisian magazine in whose beautifully-illustrated pages are depicted scenes descriptive of what might conceivably be supposed to happen were the air to contain a too generous proportion of oxygen. The reviving effects of this gas are well known, and they are fully utilised in practical medicine, but it cannot be said that death has even occurred, or even wild delirium, merely as a result of inhaling it in a more or less concentrated form. The processes of metabolism, including internal combustion, certainly go on with increased vigour when the blood is surcharged with oxygen, but it is very doubtful if the human race would become extinct by “consuming up all its organic tissue,” even were such an unlikely event as the absorption of all atmospheric nitrogen probable.

PERSONAL.

ON July 26th, His Majesty the King formally opened the new Royal Naval Hospital at Chatham. The buildings will contain 600 beds with accommodation for 90 members of the staff.

MR. PHILIP VAUGHAN has promised to subscribe £5,000 to the £50,000 the committee are raising for the Bristol Royal Infirmary.

THE name of Dr. Charles A. Hayman, of Clifton, has been added to the Commission of the Peace for Bristol.

IN accordance with the provisions of her late Majesty's Order in Council of April 1st, 1881, Fleet Surgeon William Rogerson White, C.B., has been placed on the Retired List, with permission to assume the rank of Deputy-Inspector-General of Hospitals and Fleets (dated July 17th, 1905).

DR. A. C. HOUSTON has been appointed Director of Water Examinations, Metropolitan Water Board, at a salary of £1,000 per annum.

DR. P. H. PYE-SMITH, F.R.S., and Professor J. Rose Bradford, F.R.S., have been elected Vice-Chairmen of the Committee of the Medical Members of the Senate and the Physiological and Laboratory Committee respectively in connection with London University.

MR. H. J. HUTCHENS has been selected as the Demonstrator of Bacteriology at the University of Durham.

DR. H. W. LANGLEY BROWNE, has been elected chairman of the Council of the British Medical Association for the ensuing three years in the place of Mr. Andrew Clark, whose term of office has expired.

A SCHOOL for Mothers has been recently founded in Madrid by the Marquis and Marchioness de Casa-Torre. The medical director is Dr. Ulecia, who has charge of a dispensary for sick and weakly children.

DR. MICHAEL WARNER, the well-known American physician and an old friend of Dr. Osler, has recently died, and it has been found that he had all his books containing accounts against patients destroyed so that they should not be pressed for payment.

A HANDSOME memorial has recently been erected on the highway near Sidmouth, South Devon, to the memory of the late Dr. T. Gilbert Smith. The memorial, of blue granite, is in the form of a seat, with the following inscription: "Thomas Gilbert Smith, a succourer of many. Thus closed a noble life spent in the service of his fellow men; he never turned his back on duty, but faithful to his motto, 'Dare and do,' remained undaunted to the end. On this spot at half past nine o'clock, after watching the glorious sunset of August 3rd, 1904, Thomas Gilbert Smith, M.D., F.R.C.P., fell dead from his bicycle."

THE next session at King's College Hospital will commence on Tuesday, October 3rd, when Professor T. Clifford Allbutt will distribute the prizes and give the opening address on Medical Education in London.

THE Chester Town Council yesterday appointed Dr. Albert E. Thomas, assistant medical officer of Stepney, and formerly assistant medical officer of Woolwich, to be Medical Officer of Health for Chester at a salary of £500 a year in succession to Dr. Kenyon, who had held the post for more than thirty years.

THE *Army and Navy Gazette* of July 22nd contains the following announcement: "Some changes in the personnel of the Royal Army Medical College may

shortly be expected. We understand that the professor of clinical and military medicine, Colonel K. MacLeod, I.M.S., retired, will vacate the appointment and be succeeded by Colonel David Bruce, C.B., F.R.S., R.A.M.C. Then the professor of military surgery, Surgeon-General W. F. Stevenson, C.B., R.A.M.C., retires at the end of this month and will, in all probability, be succeeded by Major C. G. Spencer, R.A.M.C., whose claims and qualifications stand very high, he being an M.D.Lond., and F.R.C.S.Eng. Further, in January next, Lieutenant-Colonel R. H. Firth, R.A.M.C., Professor of Military Hygiene, will vacate his appointment."

The Quatercentenary of the Royal College of Surgeons, Edinburgh.

[FROM OUR OWN CORRESPONDENT.]

THE quatercentenary celebration of this College, the ancient Corporation which first saw the light in the year 1505—the year of Knox's birth—was held on July 20th and 21st, and passed off throughout with the greatest success. The occasion was itself an historic one, the hosts for the time being guaranteed an hospitable reception for their guests. Few cities have greater natural advantages where such functions are concerned, and the one uncertain quantity—the weather—was all that could be desired, brilliant sunshine and warmth enabling the large numbers of people who were present at the various social functions to attend them in the greatest comfort. The official and other guests of the College and the non-resident Fellows for the most part arrived on the Wednesday, when the celebration proceedings began by a private reception, of those on whom it was proposed to confer the Honorary Fellowship, held in the College of Surgeons.

The actual commemoration proceedings were inaugurated by a religious service

IN ST. GILES' CATHEDRAL,

with which, in the pre-Reformation days the Barber-Surgeons of Edinburgh were intimately associated. In their first charter they tell how they maintained as the Church of "Sanct Geill," an altar for the honour of God, "and Sanct Mongow, oure patrone" by donation of a weekly penny, while in the present day the College aided in the restoration of the building by putting in a stained glass window in the clerestory. The commemoration service was conducted by the Rev. Dr. Cameron Lees and the preacher was the Rev. Dr. W. P. Paterson, Professor of Divinity in the University of Edinburgh, who delivered an address on the philosophy of human suffering. The honorary Fellows, delegates from learned and official bodies, assembled with the Fellows of the College of Surgeons in the Hall of Parliament House, and at eleven o'clock the academic procession entered St. Giles', to the strains of a specially composed march by the organist. First came the President, Sir Patrick Heron Watson, accompanied by the vice-president, Sir Halliday Croom. Next appeared the Hon. Fellows elect, representing most of the foreign nationalities, wearing diverse robes, uniforms and decorations, among them being Dr. John Playfair, President of the College of Physicians of Edinburgh, who brought up the rear of the Hon. Fellows elect. Next in order were the Bishop of Edinburgh, the Lyon King at Arms, the members of Parliament for the City, and the Representatives of the four Scottish Universities, preceded by their maces. After this came the main body of the College of Surgeons clad in their robes of dark blue, with light blue stoles adorned by white lace straps and tassels. Following on the academic procession came the arrival of the St. Giles' clergy, and after they had taken their places the service was begun by the singing of the 100th Psalm. Professor Paterson's sermon was from St. John, chapter 9, verses 1 to 3—"And as Jesus passed by, He saw a man who was blind from his birth, and

His disciples asked Him, saying, Master, who did sin, this man or his parents, that he was born blind? Jesus answered, neither has this man sinned, nor his parents, but that the works of God should be made manifest in him." At the outset he alluded to the ancient connection between the College of Surgeons and the church in which they were now worshipping, though the link between them had been broken at the Reformation, the old pledge in the surgeons' "Bill of Supplication" was redeemed by gathering within the same walls to pay homage to a greater God than Him they then ignorantly worshipped, and by imploring His continued benediction upon the institution which they created for the advancement of His kingdom. Apart from this link there was reason enough that the long-established and intimate relations between the healing art and the Christian Church should be prominently recognised at a celebration in which the present asserts its kinship and continuity with the past. It was true that at certain periods the Church attempted to obstruct the march of science and retarded to some extent the development of a rational system of medicine; but as an offset to this it must be remembered that amid the shocks and losses of the Middle Ages the Church was the chief custodian of the scientific legacy from antiquity, which saved the world from intellectual bankruptcy, while the enthusiasm of humanity which had supplied the moral dynamic of the medical profession in the modern western world had chiefly been engendered by the religion which adored in a Good Physician God made manifest in the flesh, and which proclaimed the infinite value of every human being as made in the image of the eternal God. The central topic of the discourse was then reached—the problem of human suffering. The preacher contrasting the old-world idea that it was sent as a penalty, with the Christian view that a world of disease was a world of opportunity, and that it created for man the possibility of doing works like unto those which had their spring in the wisdom and magnanimity of their Father in Heaven. Christ's remarkable saying in their text as to the chief end of suffering, found its most obvious application in the use of medicine and surgery. A grim necessity, as Hippocrates said, was the mother of the healing art. In the work of responding to the imperious summons of distress and suffering, the human mind had discovered and matured its latent powers, and entered on a course of brilliant discovery—work in which every age and grade of civilization took a share according to its capacity. To the preacher it seemed as important to consider whether, apart from the necessity which suffering laid upon man to question the basis of things, the edifice of science in anything like the design and proportions that they knew it, would have existed on earth at all. In conclusion, Dr. Paterson next considered how suffering had reacted on man's moral nature and pointed out that the chief tributary of the religious life of mankind had its sources in the region of sickness and in the valley of the shadow. Microscopic views of things and short views of history might cloud and overshadow the sight of the hand of God, and the perception of the impress of the designing mind, but the universe as a whole was too deeply saturated with wisdom, cosmic processes too cunningly framed, the interest in human history too surprising to make it conceivable that the higher teleology would not permanently command the assent of sufficiently instructed and thoughtful minds.

LUNCHEON BY THE TOWN COUNCIL.

After the commemoration service in St. Giles' the company to the number of about a hundred adjourned to the Council Chambers, where the principal guests and office-bearers of the College and others were entertained to luncheon by the Corporation. After the loyal toasts, the Lord Provost proposed "The Royal College of Surgeons," offering to the College, and to the guests who had honoured the capital with their presence, a most cordial welcome. On his right hand he had one whose name was a household word in Edinburgh, Sir Patrick Heron Watson, than whom

there was no better friend, no better medical adviser, and no kindlier heart in the city. On his left he had the President of the Royal College of Surgeons of England, and they were very proud to have him with them. On his right again he had the President of the College of Surgeons of Ireland. They might differ on the question of Home Rule, but this city was his home for the time being. To these, to Major-General Keogh, representing the Army, and to Mr. Ellis, representing the Navy, to the illustrious foreigners who were sitting at the board beside them, to one and all, in the name of the Corporation, he offered hearty welcome. They were very glad indeed to recognise the debt of gratitude which they owed to the College of Surgeons, and, on the other hand, he thought the College owed gratitude to the city for its incorporation. It was a fact that the City of Edinburgh granted the first charter to the College of Surgeons, and gave it the support which was necessary for its well-being; he was not going to mention how it was supported—he supposed they would not like that now—but they had all been humble in their lives and had had small beginnings. None of their foreign visitors would deny, notwithstanding the long existence of the University of Paris, to which the Scots had been deeply indebted, that the College of Surgeons and the University of Edinburgh had been to a very large extent one of the leading schools of medicine in the world. In common they did not tell anybody what they owed; in the medical profession, however, they gave freely to each other all their experience and knowledge, retaining nothing for themselves, but believing it was their duty to do all they could for the welfare of the people at large. Had Jenner or Harvey been commercial men, their discoveries would have been sold at a high price, but the medical profession, happily, did not move on these lines. All knew how much they owed to Pasteur and Virchow—honoured names in the hierarchy of science. In coupling with the toast the name of the President of the Royal College of Surgeons, he said that but for Sir Patrick Heron Watson they would not have had the present Lord Provost in the chair that day.

The toast was briefly replied to by Sir Patrick Watson, and thereafter the proceedings terminated to enable those present to attend the principal function in the proceedings.

THE COMMEMORATION CEREMONY IN THE McEWAN HALL.

The central features of this ceremony were the presentation of honorary Fellowships to a number of distinguished European and American physicians, and the reception by the College of Surgeons of congratulatory addresses from learned and scientific societies and corporations. The interior of the McEwan Hall has seldom presented a more striking spectacle than on Thursday afternoon: The area was reserved for those more immediately connected with the ceremony—the magistrates and Town Council, clergymen of various denominations, university officials, representatives of the Faculty of Physicians and Surgeons of Glasgow, and the Fellows of the two Royal Colleges of Edinburgh; while the galleries were occupied by the general public, mostly ladies in the brightest of summer garb. By request of the college, most of those invited wore uniform or academic costume, and for once the sterner sex competed on level terms with their sisters and wives; the crimson of the full dress doctor's robe jostling the blue and silver of the surgeons, while the more sombre black and crimson robe of the Edinburgh College of Physicians contrasted with the brilliant yellow facings of their colleagues from Glasgow. Academic hoods in every colour—crimson, red, purple white, blue, green—formed a striking colour picture, while here and there a military or naval uniform caught the eye by its contrast with the robes of peace and learning. The interval of waiting for the arrival of the platform party was filled by an organ recital by Mr. T. H. Collinson, Mus. Bac. (Oxon.). At four o'clock the College mace appeared, followed by Sir Patrick Heron

Watson and the Lord Provost of Edinburgh. The order of procession was as follows :—

- The Mace.
- The President.
- The Right Hon. the Lord Provost of Edinburgh.
- The Right Rev. and Right Hon. the Moderator of the General Assembly of the Church of Scotland.
- The Right Hon. the Earl of Stair.
- The Lord Justice-General.
- The Lord Justice-Clerk.
- The Senators of the College of Justice.
- The Solicitor-General for Scotland.
- Lyon King-of-Arms.
- The Principal of the University of Edinburgh.
- The President of the General Medical Council.
- The Select Preacher—The Rev. Prof. Paterson, D.D.
- The Right Hon. the Lord Provost of Glasgow.
- The Member of Parliament for the Universities of St. Andrews and Edinburgh.
- The Member of Parliament for East Edinburgh.
- The Right Rev. the Bishop of Edinburgh.
- The Most Rev. the Archbishop of St. Andrews and Edinburgh.
- The Vice-President.
- The Honorary Fellows Elect.
- Secretary and Council of the Royal College of Surgeons of Edinburgh.
- Ex-Presidents of the College
- The President's Chaplain.
- The University Court, University of Edinburgh.
- The Vice-President, Treasurer, and Council of the Royal College of Physicians of Edinburgh.
- The Visitor, Treasurer, and Council of the Faculty of Physicians and Surgeons of Glasgow.
- Representatives of the Army and Navy.
- Representatives of the University of St. Andrews.
- Representatives of the University of Glasgow.
- Representatives of the University of Aberdeen.
- Representatives of the University of Edinburgh.
- Representatives of University College, Dundee.
- The Clergy.
- The Magistrates of the City of Edinburgh.
- The Provost of Leith.
- Representatives of Legal Societies.
- Representatives of Medical Societies.
- Representatives of Scientific Societies.
- Representatives of Public Bodies.
- Non-Official Guests.

The President of the Association of Diplomates of Scotland, Dr. St. Aubyn Farrer, was officially present at the Quatercentenary. Other representatives of the same Association were the Hon. Treasurer and Dr. David Walsh, the Honorary Secretary.

As soon as the distinguished party was seated, the President delivered an address of welcome to the brilliant assemblage which had responded to the invitation of the College. He remarked that the origin of the Royal College of Surgeons as a corporate body must be traced back to the reign of James IV. of Scotland, who on October 13th, 1506, confirmed by Royal Charter the "Seill of Cause," which a year previously in July, 1505, had been granted to the Barber-Surgeons resident within the Burgh of Edinburgh, by the Provost, Bailies, and Council of the Burgh. There was, however, he said, reason to believe that even prior to this date an organised body of practitioners had already existed in Edinburgh, to whose laudable desire for an accredited position, and for authority to practise and to teach, the College is indebted for its inception. This body, by its energy and indomitable perseverance, met and overcame the difficulties which stood in its way; and when one recalled the comparatively barbarous condition of the country at that time, and the terrible strife by which it was torn, it was impossible to do otherwise than regard with admiration and respect the work which those men were able to accomplish as pioneers of a great cause. Time, continued the President, would fail him were he to venture on a full development of the history of the Royal College of Surgeons of Edinburgh. He also felt that he must refrain from encroaching upon the time which had still to be devoted to the more important duties of that day. In conclusion, he expressed the grateful appreciation of the College, of the generous consideration manifested towards them by the sister corporation—the University of Edinburgh—in according to this meeting the use of the McEwan Hall. In doing so, he could not refrain from expressing the deep sense of regret which all felt in the lamented death of the late Principal of the University, Sir William Muir.

At the close of the address, the Secretary of the College constituted the meeting according to the usual form of the College of Surgeons, by reciting the following prayer, which tradition asserts to have been composed by John Knox:—"O Eternal God, our loving and merciful Father in Christ Jesus—Seeing we are convened to treat of those things which concern our calling: We beseech Thee, O Lord, to be merciful to us, and give us grace to proceed therein without malice, grudge, or partiality: So that the things we do may tend to the glory of God, the weal of our vocation, and the comfort of every member of it: Through Jesus Christ, our only Lord and Saviour. Amen."

THE HONORARY FELLOWSHIPS.

Following on this came the ceremony of admitting the Honorary Fellows. The promoter, Sir Halliday Croom, Vice-President of the College, submitted a short account of the circumstances of the career of each of these, who were the selected representatives of international surgery. As the Fellow-Elect mounted the platform steps the organist played a few bars of his national hymn, he received the right hand of Fellowship from the President, who then presented him with his diploma, while the officer of the College robed him in the gown of his new dignity. The admission was completed by the signature of the College Roll. All the recipients of the Fellowship were heartily applauded; it was perhaps noticeable that the French, Japanese, and American names were greeted with the loudest cheers, but of all the names mentioned, that of Baron Lister came in for the chief ovation. The following Honorary Fellowships were conferred :—

Professor v. Eiselsberg.—May I, said the promoter, introduce Anton, Baron v. Eiselsberg, Hofrath and Professor of Surgery in the University of Vienna. Amongst his more important publications are his contributions to our knowledge of the thyroid gland and of the elimination of pyogenic organisms by the skin. He studied under Billroth, and in 1893 was appointed to the chair of surgery at Utrecht; two years later he succeeded Braun at Königsberg, and has proved himself a worthy follower of the great Billroth.

Professor Fuchs.—No one occupies a higher place in ophthalmic surgery than Ernst Fuchs, the distinguished professor of Ophthalmology and Director of the First Division for Eye Diseases on the Allgemeines Krankenhaus, Vienna. His reputation is world-wide, and he is a recognised authority on the pathology of the eye. Famous as a teacher, he is the author of a standard work on diseases of the eye, which has been translated into almost every language. I ask you to confer the Fellowship on him *in absentia*.

Professor Saxtorph.—Silvester Saxtorph, of Copenhagen, has held many important posts in Denmark, amongst them Surgeon to his Majesty the King of Denmark; he was appointed Professor of Surgery in 1894, and made a Knight of the Order of Dannebrog in 1898. He has contributed many papers to learned societies, especially on subjects connected with disease of the urinary tract.

Professor Guyon.—F. C. Felix Guyon, Professor in the Paris Faculty of Medicine, is a foremost exponent of genito-urinary surgery; he is a member of the Academy of Science and the Academy of Medicine, and is the recognised leader of the Parisian School of urinary surgeons. I ask you to confer on him the Fellowship *in absentia*.

Professor Lucas Championnière.—M. Just Lucas Championnière was one of the first European surgeons to come to study in Edinburgh under Lister; one of his earliest books was on antiseptic surgery, while he is best known by his writings on hernia, and the treatment of fractures by massage.

Professor Poncet.—No one among the provincial French surgeons stands higher than M. A. Poncet, Professor of Surgery at Lyons, who is famous for his work on bone diseases, affections of the bladder, and actinomycosis. He succeeded Ollier in the Chair

of Surgery, and operated on the late President Carnot when he fell a victim to the assassin. I beg that the Fellowship be conferred on him *in absentia*.

Professor Segond.—It is a special pleasure to present a gynaecological specialist in Dr. Paul Segond, Paris, who is a distinguished operator, teacher, and writer, and whose clinical and pathological work has been recognised as of the utmost value. No one has a higher position than Dr. Segond, who is a typical representative of Parisian gynaecology.

Professor Terrier, member of the Academy of Medicine and Professor of the Surgical Clinique of the Faculty, a celebrated surgeon not only in practice but as contributing largely to surgical literature. The honorary Fellowship was conferred *in absentia*.

Professor von Bergmann.—Among the many distinguished surgeons of Germany, no one stands higher than he. Beginning as assistant at the Surgical Clinique at Dorpat, he served under Wagner through the Bohemian war, and under Billroth and Volkmann in the Franco-German War, in which he saw the siege of Paris. In the Russo-Turkish war of 1877-8 he was present at the siege of Plevna, and since 1882 he has been the chief apostle of the famous Berlin School of Surgery, standing at present in the forefront among German surgeons. I ask you to confer the Fellowship *in absentia*.

The list of honorary Fellowships will be concluded in our next issue.

British Medical Association.

SEVENTY-THIRD ANNUAL MEETING, JULY 24TH TO 28TH.
[FROM OUR SPECIAL CORRESPONDENT.]

SECOND ARTICLE.

THE Leicester Meeting has been a distinct success, well attended, rich in hospitality and social gatherings, and fruitful in scientific work. Leicester is a clean, active, progressive town, a focus of business enterprise and an excellent example of wise municipal government. Every member received a copy of a dainty "Guide to Leicester and Neighbourhood," produced under the auspices of the Local Executive Committee of the Association. The enterprising firm of Burroughs Wellcome and Company also presented an elegant little handbook to every visitor on "Leicester Medical Lore." Excellent arrangements were made for the comfort and convenience of those attending the meetings. The members' card contained a good map of the town. The reception room was centrally situated in the Y.M.C.A. buildings, and here the Council met and the business meetings were held. The Sections gathered in the various rooms of the admirable Technical Schools, and here also was located the very attractive and well-arranged Pathological Museum. The Annual Exhibition, which was fairly representative, was held in the Drill Hall and Magazine Square, and was well attended. The general arrangement of rooms for members, visitors, ladies, and representatives of the Press was good. The annual service was held in St. Martin's Church on July 25th, at 5 o'clock, and was well attended, the Right Rev. the Lord Bishop of Birmingham delivering the sermon. A Roman Catholic service was also held at the same time.

The meetings of the Council and the gatherings of the representatives took up much time during the first few days, but under the new constitution the great body of members seem to evince but little interest in the business duties of the annual conference. The chief event affecting the future of the Association was the decision to attempt to secure a Royal Charter, thereby giving additional powers and gaining release from undesirable restrictions the working of which was not clearly recognised when the new Constitution was adopted.

The Address of the President, Mr. George Cooper Franklin, F.R.C.S., was delivered on the evening of Tuesday, July 25th, in the Royal Opera House, and dealing to some extent with the medical history of Leicester, was well received. A number of foreign

guests and Colonial delegates were received, and the Association's Gold Medal of Merit was presented to Sir Constantine Holman, M.D., and Mr. Andrew Clark, D.Sc., F.R.C.S.

The Address in Medicine was delivered on Wednesday, July 26th, by Henry Maudsley, M.D., LL.D., F.R.C.P.; and the Address in Surgery by Mr. Charles John Bond.

The Nineteenth Summer General Meeting of the Irish Medical Schools' and Graduates' Association, which now numbers 856 members, was held on Wednesday. There was a large attendance of members. In the absence of the President, Sir William Whitla (Belfast), who wrote to express his regret at being unable to be present, Dr. Alfred Freer, as the senior foundation member present, was voted to the chair. The Chairman called on Dr. Stewart to address the meeting in reference to the question of the monopoly of honorary hospital appointments in England. He detailed the efforts that had been made in four cases successfully, to have the exclusive rule repealed which restricted these appointments to those holding the diplomas of two particular colleges. He said that there was prominent in the English character the love of justice, and that when the governors of the institution in which the restrictive rule existed had it brought home to them how unfair it was to put obstacles in the way of those holding such high qualifications as the F.R.C.S.I. and M.R.C.P.I., they gladly carried out the principle of the "open door" and repealed the obnoxious rule. But the difficulty was the expense of bringing the facts of the case under their notice. He (Dr. Stewart) was glad, however, to say that, with the prospect before them of a large accession of new members, the Council had determined to enter soon upon another assault on a monopoly fortress and he was sanguine of the same success as had attended similar efforts at Bristol, Hastings, Brighton, and elsewhere.

On Thursday morning, the National Temperance League gave their annual Breakfast, which is now officially recognised and is undoubtedly one of the best attended and most enjoyable functions of the meeting. The Annual Dinner was held in the evening in the County Assembly Rooms.

On Friday night, July 28th, Professor William Stirling delivered a popular lecture on "Fatigue and Repose."

During the week special meetings were held in connection with the New Sydenham Society, the Irish Medical Schools' and Graduates' Association, the Continental Anglo-American Medical Society, and the United Kingdom Police Surgeons' Association.

A number of very attractive and largely attended garden parties were given. On Wednesday, July 26th, the Chairman of the Leicester Infirmary gave a garden party in the Infirmary grounds, and this afforded excellent opportunity for inspecting the admirable new out-patients' department and the recently opened wing containing well-equipped operation theatres.

On Thursday, July 27th, garden parties were given at the County Asylum, and at Humberstone Hall, the residence of Mr. Maurice Levy, M.P.

On Friday, July 28th, Mr. and Mrs. Samuel Faire gave a garden party at Glenfield Firth.

Various receptions, entertainments, and evening fêtes were held in the evenings.

During the week many factories and municipal and other works were open for inspection.

On Friday, July 28th, at the invitation of the Duke of Rutland, a party visited Belvoir Castle.

Saturday, July 29th, was devoted to excursions and members visited Buxton, Haddon Hall, Chatsworth, Matlock, Castleton, and Charnwood Forest.

A number of members also availed themselves of the kindness of the Leicestershire County Cricket Club and were present at the contest between Leicestershire and Derbyshire.

It should also be mentioned that the enthusiasts of the links were well provided for.

The Local Committees are to be congratulated on the

results of their labours. "The Annual Picnic" has come and gone, and now there remains pleasant memories, the renewal of old friendships, the formation of fresh bonds and we may venture to hope a quickening of the spirit of fellowship and goodwill throughout the Association.

The next meeting is to be held in Toronto in Canada.

THE WORK OF THE SECTIONS.

Although no discovery or startling announcement of conspicuous scientific value can be placed to the account of the Leicester meeting, the discussions held and the various papers read in connection with the different sections have done no little to stimulate and encourage individual workers, and something to advance medical science and improve the healing art.

There were twelve sections; the attendance in some few was fairly good, but generally speaking the members participating were, to say the least, not numerous. In one sparsely attended section we found the select few engaged in smoking. It is much to be regretted that the scientific work of the Association should be so neglected. While elaborating the machinery for professional protection and trade union, it is most desirable that the scientific spirit should be maintained and be afforded adequate means for expression.

MEDICINE.

The Discussions in the Medicine Section attracted good gatherings. Sir Lauder Brunton discoursed on the treatment of sleeplessness and pain; Dr. Howard Tooth dealt with the pathology, diagnosis and treatment of various forms of acute meningitis; and Professor Julius Dreschfeld opened the discussion on the diagnosis and treatment of cardiac degeneration apart from valvular disease. No epoch-marking announcement was forthcoming, but much serviceable material was presented and many valuable facts and opinions focussed and fixed. The greater part of the time was devoted to the consideration of the above subjects and only a very few papers were presented.

SURGERY.

The Surgery Section was generally well attended. Mr. B. G. A. Moynihah's introduction to the discussion on the surgical treatment of non-malignant diseases of the stomach, was a thoroughly optimistic presentation, and gave rise to a free expression of opinion from many well-known members. The discussion on the treatment of malignant disease of the rectum was opened by the President of the Section, Sir Charles Ball. A number of papers were also read.

STATE MEDICINE.

This Section attracted many enthusiastic students of so-called preventive medicine. The much-disputed subject of hospital isolation for infectious disease was dealt with by Dr. George Wilson; sanatoria for the poorer consumptives was discussed by Dr. L. A. Weatherly, Dr. Kelynack, Dr. T. D. Lister, Dr. Nathan Raw, and others. Dr. Kelynack's paper on "Alcohol in Relation to National Vitality," gave rise to an important discussion, and it was unanimously resolved to recommend the Council to appoint a Special Committee to enquire into the alleged influence of alcoholism in lowering national vitality.

Baillie W. F. Anderson opened a discussion on "Infants' Milk Depots." "What is Notifiable Diphtheria?" formed the subject of a discussion carried on in conjunction with the Section of Laryngology, and was opened by Dr. P. Watson Williams. Several papers of public interest were also read in this section.

INDUSTRIAL HYGIENE AND DISEASES OF OCCUPATION.
The discussions held by this section, dealt with physical deterioration, anthrax, and accident and poisoning reports.

LARYNGOLOGY, OTOLOGY, AND RHINOLOGY.

On this occasion friends and foes formed a triple combine and much interesting discussion ensued. Dr. William Milligan opened the discussion on the lines of treatment in preventing acute middle-ear suppuration from becoming chronic. The treatment of tuberculous disease of the larynx was dealt with by Dr. Jobson Horne, Dr. Habershon, Dr. Harold Barwell, and others. A number of instructive papers were also read.

NAVY, ARMY AND AMBULANCE.

This Section attracted but a small number of members, but several papers dealing with many practical matters were read and considered.

OBSTETRICS AND GYNÆCOLOGY.

Professor Wertheim opened the discussion on "The Diagnosis and Treatment of Cancer of the Uterus"; and a consideration of the treatment of albuminuria and eclampsia occurring in pregnancy was opened by Dr. Robert Boxall. Many members took part in these important discussions, including several "lady practitioners." A number of useful papers were also presented.

OPHTHALMOLOGY.

Mr. Walter H. H. Jessop opened a discussion on intraocular tuberculosis; and Mr. E. Treacher Collins pointed out the various capsular complications which may occur after cataract extraction. A number of papers were also read.

PSYCHOLOGICAL MEDICINE.

Several matters of much interest received consideration in this select section, such as "The Clinical Study of the Heredity of Insanity," "The Occupation and Environment as Causative Factors of Insanity," and "Prognosis in Mental Disorders."

PATHOLOGY.

The President, Dr. F. W. Mott, opened a valuable discussion on the "Relationship of Heredity to Disease," in which Dr. Archdall Reid and others took part. Several papers of interest were read.

DENTAL SURGERY.

This Section was presided over by Mr. Morton Small, who delivered a short introductory address. A useful and lengthy discussion "Toothache, Neuralgia and Remote Affections of Open Origin" took place, in which many specialists and members participated. Several papers were read and considered.

TROPICAL DISEASES.

The subjects of tick fever, tropical diseases of the skin, and sprue, and hill diarrhoea were dealt with, and a number of papers were also read.

The Annual Exhibition of Foods and Drugs, including prepared foods, chemical and pharmaceutical preparations, medical and surgical instruments, antiseptic dressings, and appliances, books, diagrams, &c., was a thoroughly representative "show," and although several old firms were conspicuous by their absence, the exhibition was a thorough success and well patronised. A special feature of the show was the good collection of motor cars and accessories.

We shall hope to deal with the more important exhibits in our next issue.

Correspondence.

THE ANGLER'S HOLIDAY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—So many readers of your journal are disciples of old Walton, that they will be gratified to hear of the admirable arrangements made this season for the protection of *amateur angling* by the Lucerne municipality. Since November last all such fishing has been limited to lines, restricted to certain months annually, and always only authorised by special permits. The cost of these permits is most reasonable, running from 10 francs for one month to 40 francs for nine months. The number of lines for each boat for lake fishing is limited to two, and the sizes of fish strictly defined; all caught smaller than certain dimensions to be immediately replaced in the waters. All particulars about fishing regulations can be obtained from the Official Inquiry Bureau, Lucerne.

This "new departure" of the liege-lords of Lucerne adds to the already numerous attractions of their beautiful city. Its great accessibility, exquisite situation, superb surroundings, multiplicity of excursions and entertainments on land and water, abundant and varied scope of hotel, pension, and apartment life, mingling together here of the antique and the modern, have made Lucerne an unsurpassed centre for continental summer tourists.

I am, Sir, yours truly,

W. G. M.

RECTAL FEEDING.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—With reference to your remarks on the above subject in your last issue, may we be permitted to draw attention to the experiments made by Hoppe, and published in the *Munich Med. Wochenschrift*, No. 51, 1904? Hoppe's Enemata were made up of sanatogen, and it is interesting to note that the percentage of absorbed material ranged from 77 to 81, an,—to our mind,—unusually high figure. It would seem from these experiments that albumen, as present in sanatogen, holds an important place as a means of feeding by the rectum. So far we are not aware of any experiments having been made with sanatogen as an enema here in England, but we think that those interested in the subject would find it worth their while to make a trial in that direction.

We are, Sir, yours truly,
THE SANATOGEN COMPANY.

83, Upper Thames Street, London, E.C.
July 27th.

TREATMENT OF RINGWORM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your annotation on School Ringworm, it is stated that "under the most skilled treatment the disease lasts from six months to two or three years or more." I have had much experience in the treatment of ringworm at the Plymouth Public Dispensary. Of late years I adopted the treatment of the late Dr. Illingworth: he suggested the use of the biniodide of mercury.

My practice was to closely cut away the hair for a distance of a quarter of an inch or more surrounding each bald spot, and on such cleared space, and even further around, to apply the solution suggested by Dr. Illingworth. I always applied it myself on the first visit of the child, that the mother might see how to act. I allowed the solution to soak well into the skin and follicles, rubbing it into the space with a brush.

The results were most satisfactory. It appeared to me often that the disease was arrested in a week or a few weeks.

Dr. Illingworth's solution was made of hyd. biniodid. 1 drachm; sodii iodid., 2 drachms; aq. dest. to 1 oz. This made a solution of one in eight. In practice I diluted it to one in a hundred, more or less. Dr. Illingworth said that one in a thousand was adequate.

The solution was applied once in twenty-four hours. I carefully instructed mothers to omit it for a day or two if any redness or soreness followed its use.

I hope that Dr. Illingworth's suggestion, if tried in great schools, may confirm the value of his practice. A general treatment with malt extract or cod-liver oil was also carried out if indicated.

I am, Sir, yours truly,
WILLIAM H. PEARSE.

Plymouth.

INFANT MORTALITY AND QUACK
NOSTRUMS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The proprietors of Woodward's Gripe Water do not furnish an address, and I have failed to obtain the name of the medical officer alluded to in the following advertisement which appears in the daily papers:—"Infant mortality is mainly due to intestinal troubles. I am thoroughly satisfied that 'Woodward's Gripe Water' is a safe and reliable remedy."—A Medical Officer of Health (name given privately). Sold by all chemists, grocers' stores, price 1s. 1½d."

Would it not be possible for one of our medical defence societies to ascertain the identity of the gentleman in question and to communicate it to the Medical Council. Medical readers do not need to be told that the cure of "intestinal troubles" in infancy by a medicine would approach the miraculous, and they do not believe in miracle-mongers who work by secret remedies for gain alone. The amount of harm that

may be done when dealing with infantile complaints by reliance upon drugs when the true cause lies in improper food and feeding is deplorable; but no doubt some people find consolation in the fact that the proprietors of the Gripe Water, at any rate, must be making a large income out of their nostrum, else they could not afford to spend thousands a year in advertisements.

I am, Sir, yours truly,
AN OBSCURE PRACTITIONER.

July 26th, 1905.

A "VACANCY IN ALGIERS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—My attention has been called to certain advertisements and circulars emanating from a gentleman in holy orders *sine cura*, soliciting applications from English medical men provided with a French qualification to practise in France, to fill an alleged vacancy at Algiers. This wholly unauthorised proceeding seems to be giving rise to a very natural misunderstanding in regard to myself, and I therefore deem it wise to ask your permission to state that I have been in practice at Algiers for two years past and propose returning there in due season.

I am, Sir, yours truly,
ALFRED S. GUBB, M.D. (Paris), M.R.C.S., &c.
Aix-les-Bains, July, 1905.

Obituary.

EDMUND WADAMS, M.R.C.S.ENG., L.S.A.

MALVERN has lost one of her oldest practitioners in the person of Dr. Edmund Wadams, after a long illness. He graduated M.R.C.S. in 1843, and settled in Malvern in 1845, and for 37 years was Medical Officer, under the Upton Board of Guardians, for Malvern and Powick districts. On his retirement he was the recipient of a testimonial, Dr. Wadams, who gave up his practice in 1895, introduced to Malvern the Tallerman hot air treatment for gout and rheumatism.

CHARLES HOOPER, M.R.C.S.ENG., L.S.A.

WE regret to record the death of Mr. Charles Hooper, who died at Aylesbury on July 16th, aged 75, after a long illness. He was born at Buntingford, where his father, Dr. John Hooper, was in practice, and was educated in King's College, London, and took the diplomas of L.S.A. and M.R.C.S.Eng. in 1852 and 1853 respectively. He first went to Aylesbury as house surgeon to the present Royal Buckinghamshire Hospital, and at the time of his death had been in private practice for upwards of fifty years. He held the post of Medical Officer of Health to the Aylesbury Urban Council for a long time and for many years he was one of the honorary surgeons to the Royal Buckinghamshire Hospital, Chairman of the Aylesbury division of the South Midland branch of the British Medical Association, and an Associate of the Sanitary Institute.

Literature.

PROF. MAYO ROBSON ON THE TREATMENT OF CANCER. (a)

THE reprint of the Bradshaw Lecture, with additions, 1904, is "a protest against the fatalistic tendency to delay, and the senseless running after false gods," in the treatment of this fell disease. Its tone is hopeful in that the author, with his unrivalled experience, expresses the conviction that cancer, if discovered early and thoroughly removed, is by no means so refractory to treatment as is usually thought. Frankly sceptical as to the results of recent research into the causation of cancer, the author confesses himself equally ignorant of the predisposing conditions, but he does not despair of our ultimately elucidating these obscure problems. It is something to have established the fact that cancer

(a) "Cancer and its Treatment." By A. W. Mayo Robson, D.Sc., F.R.C.S., Senior Vice-President of the Royal College of Surgeons of England. London: Baillière, Tindall and Cox. 1905. Price 3s.6d.

is by no means restricted, as was even recently held, to the human race; indeed, its widespread incidence obliges us to study it with a wider mental aperture, so to speak. The infectivity of cancer may now be regarded as proven, and the recognition of this fact has distinctly influenced surgical conduct, especially in the direction of preventing auto-infection.

The author accepts the assumption of "pre-cancerous conditions," and advocates what we may term prophylactic operations, and his position is justifiable on the ground that we are not in possession of any means of determining the precise moment when benignancy merges into malignancy; indeed, his view is only the logical conclusion of the doctrine of early operation. This has an important bearing on the surgical treatment of chronic gastric ulcer, since this appears so frequently to pave the way to subsequent malignant growth.

The trend of experience based on statistical results may be expressed in a few words: "In many cases cancer can be prevented by treatment in the pre-cancerous stage; that, even when cancer has developed, if it be seen early and thoroughly removed, it is frequently a curable disease; and lastly, even in the later stages, much may be done by surgical treatment to give real relief."

Medical News.

Dismissal of Judgment Against Sir Patrick Heron Watson.

LAST week the House of Lords gave judgment on the appeal of Sir Patrick Heron Watson. The facts of the case were shortly as follows:—An Edinburgh lady, the respondent in the appeal, was pursuer in an action of separation and aliment brought against her husband, on the ground of alleged cruelty, which was decided against her. Sir P. Heron Watson made certain statements in the witness-box which the respondent alleged were slanderous, these statements having been prior to the trial, and with a view to giving evidence communicated by the appellant to the lady's husband and his agent and counsel. The question raised in the appeal was whether the averment of the respondent that the statements made in the witness-box were previously communicated to the respondent's husband and his agent and counsel formed a ground of action against the appellant. The Lord Chancellor, in delivering judgment, said: In this case an eminent medical man was consulted. He gave no communication to strangers or to persons outside the litigation. The communication was made to the counsel and solicitor, and in the circumstances it was the duty of the person who was to become a witness to tell the truth and the whole truth, otherwise the precognition would be worthless. He therefore moved that the appeal be allowed, and that the judgment given against Sir P. Heron Watson should be reversed, with costs. The result of the decision is that the immunity from action in respect of evidence in a court of law extends to the statement made to those conducting the litigation as to what is the nature of the evidence to be given.

Medical Sickness and Accident Society.

THE usual monthly meeting of the Executive Committee of the Medical Sickness, Annuity, and Life Assurance Society was held on July 21st. There were present the Chairman, Dr. de Havilland Hall, Dr. J. Rundley James, Dr. J. Pickett, Dr. Frederick S. Palmer, Mr. H. P. Symonds (Oxford), Mr. F. S. Edwards, Dr. F. J. Allan, and Dr. J. B. Ball. The accounts presented showed, as is usual at this time of the year, a great falling off in the number of sickness claims, but though fewer in number, the recent cases have been more than usually serious and it seems probable that several additions will have to be made to the chronic list. A large sum is paid away annually to members who, under the liberal arrangements of the Society, are entitled to annuities, generally one hundred guineas a year, till aged 65. The cost of

this was fully allowed for when the Society was founded and the reserve now amounted to about £200,000. Prospectuses and all particulars of Mr. F. Addiscott Secretary, Medical Sickness and Accident Society, 33 Chancery Lane, London, W.C.

The Royal University of Ireland.

THE following regulations for the holding of the M.B., B.Ch., B.A.O. Degrees Examinations have been adopted, to come into force at the October examinations:—

1. That the Examinations in Medical Pathology and Surgical Pathology be separated, 25 marks being assigned to each.

2. That the Pass examination shall be held in all respects in the same manner as heretofore.

3. That the further examination for Honours shall be exclusively a written examination, and only those candidates can be admitted to it who, upon their answering at the Pass Examination are specially recommended for admission by the examiners.

4. That Honours shall be awarded not on the examination as a whole, as heretofore, but in the following groups:—

(a) Medicine, theoretical and clinical, including therapeutics, mental diseases, medical jurisprudence, sanitary science, and medical pathology.

(b) Surgery, clinical, and operative, including the use of instruments and appliances, ophthalmology and otology, surgical anatomy, surgical pathology.

(c) Midwifery and diseases of women and children.

5. The candidates qualified to present themselves for Honours may select one or more of the following groups:—

6. The Honours paper shall be set on the day following the announcement of the results of the Pass Examination. They shall consist of—

(a) A paper on medicine and medical pathology.

(b) A paper on surgery and surgical pathology.

(c) A paper on midwifery and diseases of women and children.

Each paper to be of two hours' duration, and 100 marks to be assigned to each.

7. The Honours in each group shall be awarded, taking into account the entire number of the marks obtained by the Candidate at the Pass Examination in that group, together with the marks obtained on the Honours paper.

8. The Exhibitions shall be awarded, having regard to all the marks obtained both at the Pass and the Honours Examinations.

British Pharmaceutical Conference.

THE forty-second annual meeting of this body was opened at the Hotel Métropole, Brighton, on Tuesday, July 25th. This is an organisation distinct from the Pharmaceutical Society, and is solely concerned in "the encouragement of pharmaceutical research, and the promotion of friendly intercourse and union amongst pharmacists," whereas the Pharmaceutical Society is a statutory body charged with the administration of the Pharmacy Acts, and the examination and registration of those who desire to be registered under these Acts. The Conference was received by the Mayor and Mayoress at the Royal Pavilion on Monday evening, and on Tuesday morning the president, Mr. W. A. H. Taylor, F.I.C., F.C.S., of London, delivered an address, chiefly devoted to "The Standardisation Question," and the processes of the British Pharmacopoeia. Thereafter satisfactory reports of the position of the Conference were submitted, and the reading and discussion of communications resulting from researches. The meeting concluded on Thursday last. The Conference was attended by nearly 300 pharmacists from all parts of the United Kingdom, and several colonial chemists were among the number.

London School of Tropical Medicine.

THE following is a list of candidates who have passed the examinations at this School from May to July:—Dr. J. T. C. Johnson (Colonial Service), Surgeon E. R. Stitt, U.S.N., Dr. D. Mackinnon (Colonial Service), Dr. E. F. Wood (Colonial Service), with distinction; Dr. W. L. M. Goldie; Dr. J. S. Smith (Colonial Service); Dr. S. G. Allwood; Dr. E. V. Croke (Colonial Service); Dr. A. R. Wellington; Dr. E. Hopkinson, Dr. J. T. Waite, Dr. W. D. Inness, Dr. N. Beaumont (Colonial Service); Dr. H. G. Waters; Dr. T. E. F. Toovey (Colonial Service).

PASS LISTS.**Royal College of Surgeons, England.—New Members.**

AT an Ordinary Meeting of the Council held on July 27th, the following candidates having passed the required examinations, were admitted members of the College:—John H. D. Acland, Hugh W. Acton, James E. Adler, Frederick D. Atkins, Frederic C. J. Baker, George L. Birch, Herbert A. Bodkin, William C. P. Bowater, John F. Boyd, Gerald A. Bradshaw, Walter Bremner, Cuthbert G. Bromne, John Bryan, Ronald Bryden, Launcelot T. Burra, Henry Catling, Durie A. Chamberlain, Thomas C. Clare, Colin Clarke, Cecil E. Clay, Arthur R. Clayton, James E. Collins, Vyvian Colmer, Hugh P. Costobadie, Louis Courtauld, James H. Crawshaw, Malcolm O. Cruickshank, Frederick S. Davies, Langford G. Davies, Joseph B. Dawson, George F. Denning, Herbert A. De Pinna, Clive T. Edmunds, Ray Edridge, Thomas S. Elliott, Christopher Elliott, Hugh R. Evans, Percy Farrant, William H. Fleetwood, Gerald E. Friend, James G. Gibb, Edgar H. Good, Harry T. Gray, Leonard Gray, John P. Griffin, Arthur D. Griffith, Charlton R. Hall, George Hamilton, William H. Hastings, Montague L. Hine, Edward T. Holland, Herbert S. Hollis, Alfred G. Jones, Grenville P. Jones, Herbert S. Knight, Tikiri B. Kobbekaduwa, John E. Lascelles, Harold L. Laws, Rowland P. Lewis, William S. Livock, Reginald C. McDonagh, Arthur H. Macdonald, John T. Macnab, Thomas M. McPherson, Arthur H. Miller, Echlin S. Molyneux, George E. V. Morris, Gerald H. Morris, George S. Morse, Harry M. Newport, Francis M. Newton, John S. Pearson, Wilfred J. Pinniger, Theodore C. Pocock, Harold E. Priestley, Ireton G. Pritchard, Harold E. Rawlence, Harold W. Read, Vivian E. Ridewood, Ellis J. Roberts, William G. Robertson, George M. Sanderson, Ernest L. Sandiland, Robert P. Sephton, Ernest H. Shaw, Hugh G. Sherrin, Lionel Shingleton-Smith, John W. Simon, Kanwar S. Singh, Harold S. Sington, Clare O. Stallybrass, Edward J. Sunnucks, Robert A. Thomas, William R. Turtle, Cecil Vosper, Gwilym D. Watkins, Herbert A. Watney, Walter Welchman, Arthur G. Wells, Trevor H. Wilkins, William J. Wilkinson, William W. Williams, James M. Wyatt.

New Diplomates in Public Health. Granted in conjunction with the Royal College of Physicians:—Jackson A. Atkinson, Robert J. Blackham (Capt. R.A.M.C.), Neil Campbell, Herbert E. Corbin, Louis Courtauld, John W. Fox, James A. Glover, Walter L. Goodridge, Hermann L. Hamilton, Edwin C. Hayes (Capt. R.A.M.C.), Henry Holt, Percy S. Lelean (Capt. R.A.M.C.), Norman F. MacLeod, James Meek (Major R.A.M.C.), John W. Myler, F.R.C.S., John Nightingale, James F. Powell, John E. Robinson, Eugene D. Townroe.

Licences for the Diploma in Dental Surgery were granted to George Herbert Parkinson and Stanley Arthur Piper.

The statement of accounts for the year ending June 24th, with the certificate of the auditors attached thereto, was submitted and approved. It was determined to add Uppingham School to the list of institutions recognised by the Examining Board in England for instruction in chemistry, physics, and biology.

The Secretary reported that the First Congress of the International Society of Surgery will be held in Brussels, September 18th to 23rd.

Mr. Henry Morris was re-elected a Member of the Executive Committee of the Imperial Cancer Research Fund.

The subject for the Heath Scholarship Essay for 1906 is "Injuries and Diseases of the Arteries, Veins, Capillaries, and their Treatment." The essays must be typed or printed and sent in to the Professor of Surgery not later than March 31st, 1906.

Royal College of Surgeons, Edinburgh.—New Fellows.

AT a meeting of the College held on July 26th, the following gentlemen, having passed the requisite examinations, were admitted Fellows:—Lewis Beesly, L.R.C.S.E., Edinburgh; Alexander Brownlee, L.R.C.S. L.R.C.S.E., Edinburgh; Harold Branson Butler, M.R.C.S.Eng., Guildford; Duncan Macnab Callender, M.B., Ch.B., Edinburgh; Naunidh Rai Dharmavir, L.R.C.S.E., Mexborough; Augustus D'Souza, L.R.C.S.E., Edinburgh; James Ferguson, Duncan, M.B., Ch.B., Edinburgh; James Forrest, M.B., Ch.B., Blackpool; Alfred Thomas Gavin, M.B., C.M., Dunaskin; Bharat Chandra Ghosh, L.R.C.S.E., Punjab; Frederick Charles Hitchins, M.R.C.S.Eng., St. Austell, Cornwall; Mathew Holmes, M.B., Ch.B., Edinburgh; Robert James Irving, M.B., C.M., Norwich; Samuel Jesudasan, M.B., C.M., London, N.; John Arnold Jones, M.B., Ch.B., Manchester; Edwin Malcolm Lithgow, M.B., Ch.B., Edinburgh; Samuel Harvey M'Coy, M.R.C.S.Eng., St. Catharine's, Ontario; John Stewart Merrillees, L.R.C.S.E., Auburn, Melbourne; John David O'Donnell, L.R.C.S.E., Mysore, India; George Benjamin Pemberton, M.B., Ch.B., Edinburgh; Charles George Webster, L.R.C.S.E., Captain I.M.S.; and Charles Peterson Weekes, M.R.C.S.Eng., Sutton, Surrey. The Medal and set of books forming the Bathgate Memorial Prize, presented to the College by Colonel William Lorimer Bathgate, in memory of his late father, William McPhune Bathgate, Fellow of the College, were awarded to Mr. Peter Gorrie, 3 Cameron Park, Edinburgh.

Conjoint Examinations in Ireland.

AT the special examination for the Diploma in Public Health the following gentlemen passed:—Aylmer William May, M.D. Univ. Dublin; Wyndham Malan Gratton Guinness, M.D., Univ. Dublin, and Major William James Taylor, M.B., R.U.I., R.A.M.C., with honours.

Final Examination.—Archibald Crawford Adams, Israel Allaun, Thomas Somers Blackwell, Robert Andrew Brown, Thomas Walker Browne, William Wallace Boyce, William Edward Brunskill, Raymond Bury, William Charles Carson, Samuel Creighton Clarke Foster Coates, Patrick Vincent Dolan, Rodolphus Whittaker Harper, Patrick Edward Hayden, John Marcus Hayes, Henry Hosty, Luke McGuinness, Joseph James McNelis, and Henry Edward Redmond.

Third Professional Examination.—R. Adams, C. Anderson, Miss H. Beamish, R. M. Bronte, W. Carroll, M. E. Cussen, F. Coates, W. J. Deighan, R. Galgey, J. Grace, F. M. Hewson, P. M. Keane, G. H. Kinmouth, E. Montgomery, P. Mullany, P. J. McKeveitt, D. O'Flynn, J. P. O'Kane, O'C. O'Reilly, H. J. Perry, J. T. Reardon, W. C. T. Robey, and C. Sheahan.

MR. H. O. BISCHOFFSHEIM, founder of the London Ambulance Service, has generously offered to provide free an electric motor ambulance and similar vehicles later on.

PRINCE CHRISTIAN OF SCHLESWIG-HOLSTEIN presided at a meeting to found a new infirmary, to be named, by permission of his Majesty, "King Edward the Seventh's Hospital and Dispensary for Windsor and District."

THE *London Gazette* last week announced that the King, by Letters Patent, confers the dignity of a Knight of the United Kingdom upon the under-mentioned gentlemen:—Mr. Philip Sydney Jones, M.D., of Sydney, in the State of New South Wales, and Mr. Edmond Sinclair Stevenson, member of the Medical Council of the Colony of the Cape of Good Hope.

Notices to Correspondents, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CONTRIBUTORS are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when turning proofs.

DR. H. (Bedford).—You can certainly charge for advice by telephone, there is no valid reason why telephonic consultations should stand on a different footing to a letter. It is perhaps wise to make it clear at the time that a telephonic consultation is to be considered as an ordinary professional service.

INSURANCE.—(1) Total abstainers were not always regarded with favour by Insurance Companies. One of the first members of a total abstinence society founded in 1810 was refused at ordinary rates as abstinence was supposed to shorten life. (2) To decline a case outright because there is a discharge from the ear is not in practice at most insurance offices, the tendency being more and more to accept impaired lives at an increased rate. Bone disease of the inner ear, however, must be treated with the utmost caution.

MEDICAL INSPECTOR.—It has been shown both in Germany and England that women telephonists have nerve troubles transitory or chronic, most frequently paresthesia, hyperaesthesia, or vaso-motor troubles in the regions of affected nerves.

CORONER (Grimsby).—The whole subject of suicide has been ably dealt with by Dr. Wynn Westcott, Coroner for the N.E. district of London. He states that London has fewer suicides in proportion than any other town in the world, standing against Paris with only 90 per million, while that city has 400 per million.

DR. F. (Berwick).—During June 37 cases of lead poisoning and 4 of anthrax were reported under the Factory and Workshop Act, but no cases of mercurial, phosphorus or arsenical poisoning.

COLONIAL M.D.—Those suffering most severely from mosquito bites are generally run down in health. Eucalyptus in the bedroom will keep them away, and the old-fashioned "blue bag," which owes its healing properties to a small amount of ammonia, is not to be despised as an application for stings.

THE Recorder at the Old Bailey, London, last week remarked to a doctor who took the oath in the Scottish form with uplifted arm: "It is a much more sanitary and a much more solemn oath than our own, and in my opinion it ought to be made universal."

DR. HODGSON.—Your communication came to hand as we were "at press." We hope to have space for it in our next.

MR. R. H. H.—It is a matter about which we can offer no opinion.

DR. F. S. M.—The alterations are chiefly of detail and do not affect existing regulations. These will be classified and arranged in our forthcoming "Educational Number."

Vacancies.

- Cheshire County Asylum, Macclesfield.—Junior Assistant Medical Officer. Salary £140 per annum, with apartments, board, and washing. Applications to the Medical Superintendent.
- Roxburgh District Asylum, Melrose, N.B.—Assistant Medical Officer. Salary £140 per annum, with board, rooms, &c. Applications to Medical Superintendent.
- Royal Lancaster Infirmary.—House Surgeon. Salary £100 per annum, with residence, board, attendance and washing. Applications to the Secretary.
- North-Eastern Hospital for Children, Hackney Road, Bethnal Green, E.—Resident Medical Officer. Salary £100 per annum, with board, residence, and washing. Applications to T. Glenton-Kerr, Secretary.
- West Riding of Yorkshire.—Assistant to County Medical Officer. Salary £250 per annum. Applications to Trevor Edwards, Clerk to the Committee, County Hall, Wakefield.
- Bath Royal United Hospital.—Resident Medical Officer. Salary £100 per annum, with board, lodging, and washing. Applications to J. M. Sheppard, F.C.I.S., Secretary.
- Royal Victoria Hospital, Bournemouth.—A House Surgeon. Salary £100 per annum, with board and lodging. Applications to the Secretary.
- Noble's Isle of Man Hospital and Dispensary, Douglas, Isle of Man.—

- Resident House Surgeon. Salary £90 a year, with board and washing. Applications to Richd. D. Gelling, Honorary Secretary, St. George's Chambers, Athol Street, Douglas, Isle of Man.
- Parish of St. Marylebone.—District Medical Officer.—Salary £90 per annum. Applications to Henry T. Dudman, Clerk to the Board, Guardians' Offices, Northumberland Street, Marylebone Road, W.
- Salop Infirmary, Shrewsbury.—House Surgeon, Salary £100 per annum, with board, washing, and residence. Applications to Joseph Jenks, Secretary.
- Aldershot Urban District Council.—Medical Officer of Health and Superintendent of the Isolation Hospital. Salary £300 per annum. Applications to W. E. Foster, Clerk, Municipal Buildings, Aldershot.
- Royal College of Surgeons in Ireland.—Senior Demonstrator in Anatomy. Salary £100 per annum. Applications to the Registrar. (See Advt.)

Appointments.

- EARLE, R. A.** L.S.A. Lond., Medical Officer and Public Vaccinator for the Weston-super-Mare, District of the Axbridge Union.
- FRAMPTON, TREVETHAN, F.R.C.P., M.R.C.S.,** Clinical Assistant to the Chelsea Hospital for Women.
- HANCOCK, W. J., M.R.C.S., L.R.C.P. Lond.,** Certifying Surgeon under the Factory and Workshop Act for the Stalybridge District of the county of Chester.
- HILL, R. A. L., M.R.C.S. Eng., L.R.C.P. Lond.,** Certifying Surgeon under the Factory and Workshop Act for the Wimbledon District of the county of Surrey.
- LAPAGE, C. P., M.D. Vict.,** Medical Officer to the Out-patient Department of the Manchester Children's Hospital.
- MOGAVIN, LAWRIE H., F.R.C.S. Eng.,** Surgeon to the In-patients on the staff of the Dreadnought Hospital, Greenwich.
- PATERSON, MARCUS S., M.B., B.S., M.R.C.S., L.R.C.P.,** Medical Superintendent of the Brompton Hospital Sanatorium, Frimley, Surrey.
- SWAINSON, G. M. G., F.R.C.S.,** Assistant Surgeon to the North-Eastern Hospital for Children, Hackney Road.
- THOMAS, L. KIRKBY, M.R.C.S., L.R.C.P. Lond.,** Anaesthetist to the Birmingham and Midland Hospital for Women.
- TYLCOCKE, FRANK EDWARD, M.D. Vict.,** Medical Registrar to the Manchester Royal Infirmary.

Births.

- BURGESS.**—On July 29th, at Lode House, Upwell, Norfolk, the wife of J. G. Burgess, L.S.A., of a daughter.
- ROBINSON.**—On July 27th, at 1 Rue d'Aguesseau, Paris, the wife of Leonard Robinson, M.D. Edin., M.D. Paris, of a daughter.
- THOMPSTONE.**—On July 25th, at Marsh Parade, Newcastle, Staffs, the wife of Sydney W. Thompstone, F.R.C.S., M.R.C.P., D.P.H., Principal Medical Officer Northern Nigeria, West Africa, of a daughter.

Marriages.

- DAWSON—BOSTOCK.**—On July 26th, at the Church of St. John the Divine, Bedford Hill, Balham, Alfred Ernest Knight Dawson, son of the late Edward Dawson, M.R.C.S., L.S.A., of Finchfield, Essex, to Florence Agnes, eldest daughter of Declmus Crosthwaite Bostock, of Hawkhurst, Terrapin Road, Upper Tooting.
- DUPONT—FINDLEY.**—On July 25th, at the parish church of St. George's, Bloomsbury, John Munro Dupont, M.D., to Anna Townsend Findley, youngest daughter of the late George Washington Townsend, of Newburgh and New York, U.S.A.
- HODGSON—BONE.**—On July 27th, at Downhill, Glasgow, Charles Hodgson, L.R.C.P., M.R.C.S. Eng., Leyburn, Streatham, second son of Henry Hill Hodgson, Anley, to Margaret Mitchell, only daughter of Robert Bone, M.B., C.M., and Mrs. Bone, 31 Elgin Terrace, Glasgow.
- URE—DAY.**—On July 26th, at St. Marylebone Parish Church, John Francis Ure, M.A., B.C.I., (Oxon.), Barrister-at-Law, son of the late Dr. John Ure, of York, to Isabella (Kitty) eldest daughter of the late Dr. C. H. Day, of the Indian Medical Staff, and of Mrs. Day, Darjeeling, India.
- WEEKS—STEVENS.**—On July 27th, at St. Cuthbert's, Phillbeach Gardens, Harold Weeks, M.B., of 44 Scarsdale Villas, Kensington, to Mary Stevens, only daughter of the late Walter J. Stevens, of Kobe, Japan.

Deaths.

- BULLOCH.**—On July 30th, at Ragaz, Switzerland, Rosamond Majorie, wife of George J. Bulloch, of London, and younger daughter of James Frank Holland, M.D., St Moritz, aged 24.
- CONDON.**—On July 19th, at Glasnevin, Dublin, Lieut.-Col. James Hunt Condon, M.D., Indian Medical Service, R.L., in the 73rd year of his age.
- GRINDROD.**—On July 29th, at Gaytonhurst, Heswall, Cheshire, Cyril John Wedemeyer Grindrod, M.R.C.S., L.R.C.P. Lond., fifth son of the late Rev. W. Grindrod, vicar of Ane, Yorkshire.
- MCLINTOCK.**—On July 30th, at Church Stretton, Shropshire, Hannah, widow of the late J. R. McLintock, M.D., aged 83.
- MORRIS.**—On July 30th, at Hamilton House, Leamington, Joseph Morris, M.R.C.S., L.R.C.P. L.S.A., aged 70 years.

Original Communications.

THE DIAGNOSIS OF TUBERCULOUS LARYNGITIS IN ITS EARLY STAGE. (a)

By HAROLD BARWELL, M.B.LOND.,
F.R.C.S.ENG.

Laryngologist, Mount Vernon Hospital for Consumption; Assistant Surgeon, Metropolitan Ear, Nose, and Throat Hospital; Consulting Surgeon for Throat and Ear Diseases, Cripples' Home for Girls; Clinical Assistant to the Throat Department, St. George's Hospital.

GENTLEMEN,—I want to impress upon you, and I should like to impress upon the entire profession, the great value of the inspection of the larynges of consumptives at regular intervals as part of the routine management of such cases, and for the following four reasons:—

Tuberculous laryngitis, though principally a complication of the advanced stage of phthisis, is by no means uncommon at all periods of consumption; it frequently causes no symptoms whatever until it is comparatively far advanced; it is often curable at its onset, much more so than when the larynx is extensively involved; and, finally, if neglected, it causes one of the most painful forms of death which a man may suffer. To my mind these are unanswerable arguments that it is the duty of medical men to examine the throats of consumptive patients as a matter of routine, whether laryngeal symptoms are present or not. This is done here, at the Mount Vernon Hospital, and it is largely to this that I attribute the high percentage of local cures that we obtain; and if this method were generally followed I am convinced that a great deal of suffering would be prevented.

It is clear, therefore, that the diagnosis of tuberculous laryngitis in its early stage is a subject of great importance, that treatment may be begun when there is a fair chance of cure, for routine inspection without arriving at a diagnosis is naturally useless.

The disease is often most easy to recognise at a glance, but sometimes the diagnosis is extremely difficult. It would seem superfluous to remark that all cases of laryngeal disease in consumptive patients are not tuberculous laryngitis, but a decided tendency exists to diagnose them as such. Nevertheless it is astonishing what a number of other forms of laryngeal disease I see among the

consumptive patients in this hospital; chronic laryngitis and pachydermia are very common in phthisical patients, but I also see a large number of cases of laryngeal syphilis and a sprinkling of other lesions, such as new growths.

There is a very general opinion that pallor of the laryngeal mucous membrane is characteristic of tuberculous laryngitis. This, however, is by no means really the case. Consumptive patients are often anæmic, and then the larynx, in common with the palate, fauces and other mucous membranes, will be pale; but if the patient be not anæmic, the colour of the larynx is normal, or even reddened from irritation or secondary infection. Tuberculous granulations are usually pallid, and the margins of ulcers are not injected; the massive swellings of the arytenoid region are often, but by no means always, pale, especially if œdematous. Even then, the unaffected parts of the larynx have no characteristic tint, and very often tuberculous infiltration, especially on the cords, ventricular bands and epiglottis, has a deeply congested red appearance. An anæmic larynx means that the patient is anæmic, and is no proof whatever that the larynx is affected with tubercle.

Tuberculous ulcers are very slow in growth; the edge is extremely ill-defined and has no surrounding zone of injection; it is undermined when the ulcer is deep, but tuberculous ulcers tend to spread superficially rather than deeply. The base is set with granulations, and often presents a characteristic yellowish, "speckly" appearance; in the interarytenoid region these granulations are apt to become exuberant and form large, soft, irregular masses. On healing, there is no excessive formation of scar-tissue, and contraction and deformity are of the slightest.

Laryngeal tuberculosis assumes many different forms, and it will be convenient to discuss their diagnoses separately. Three principal types may be described—the aryteno-epiglottic, the chorditic, and the interarytenoid. The aryteno-epiglottic type of the disease affects chiefly the upper aperture of the larynx; attacking the arytenoids first, it slowly spreads outwards along the aryteno-epiglottidean folds, until at a later stage it involves the epiglottis. When small, the arytenoid swelling is oval, but when large it assumes a characteristic pyriform or flask-shaped aspect. As the submucous tissue is plentiful here, the swelling may reach a great size and ulceration is rare and occurs late; the infiltration is bilateral, though one side may be more affected than the other. It is usually pink or red in colour, and is

(a) A Post-graduate Lecture, illustrated by drawings and cases, delivered at the Mount Vernon Hospital for Consumption, on July 13th, 1905.

pale if œdematous. This arytenoid infiltration is almost pathognomonic, for no other chronic affection shows this symmetrical swelling. In œdematous laryngitis this region is much swollen, but where the disease is obviously acute, the onset is sudden, fever is high, and the rest of the larynx is in a state of acute inflammation.

Again, the arytenoid region is a not uncommon site for the formation of a gumma; the tumour, however, is unilateral, and more firm and solid in appearance; it usually breaks down to form a deep "crateriform" ulcer, with a sharply punched-out edge surrounded by a zone of injection, the base of which is thick and hard, and is often covered by a yellow mass of necrotic tissue. The amount of pain is no criterion, for a gumma on the arytenoid may cause the most severe dysphagia.

A malignant growth on the arytenoid region is unilateral, firm and hard, red and angry looking; it ulcerates early, and is more likely to resemble syphilis than tubercle.

The epiglottis is very rarely attacked in the early stage of tuberculous laryngitis, and the rest of the larynx is usually already extensively diseased. In contradistinction to syphilis, the laryngeal surface is always the most severely affected; extensive destruction of the epiglottis, without much disease in other parts of the larynx is nearly always due to syphilis. The so-called "turban-shaped" epiglottis, combined as it always is, with arytenoid infiltration, is absolutely pathognomonic of tubercle, but it is quite rarely seen.

When the tuberculous process begins by attacking the vocal cords, the diagnosis may be much more difficult. The lesions are most marked on the posterior half of the cords and on the cartilaginous glottis, and assume a great variety of forms. In the earliest stage there may be merely a diffuse redness of the cords indistinguishable from that produced by catarrhal laryngitis. Simple laryngitis is very common in consumptive patients, and is due partly to the strain of coughing, and partly to the irritation of the sputum; such cases should be treated promptly by rest and soothing inhalations, lest tuberculous infection supervene. As a rule, even at its onset, tuberculous infiltration of the cords shows certain peculiarities which enables the diagnosis from simple laryngitis to be made with certainty. Even when there is simply redness of the cord, it is generally decidedly more advanced on one side than the other, and, indeed, is not uncommonly confined to one cord; this unilateral congestion is never due to catarrh, but always to tubercle, syphilis, injury or early malignant disease. As a rule, too, tuberculous infiltration produces more than a simple redness and swelling. A speckly red appearance, described by Lake as "chorditis granulosa," is very characteristic; at other times the cord is converted into a firm pink nodular, tumour-like mass, or, again, it may resemble a smooth, broad band of red granulation-tissue, which adheres somewhat to its fellow as the cords separate after phonation. These three appearances are common enough, and are easy to distinguish from simple catarrh. Small erosions may sometimes be seen in simple laryngitis, but definite ulceration does not occur.

When catarrhal laryngitis has been excluded, the diagnosis must next be made from laryngeal syphilis. Both secondary and tertiary syphilis often attack the vocal cords; as in tuberculous,

the affection is often most marked on one side and it may produce simple congestion, or a nodular or smooth mass of infiltration; the scattered red specks of "chorditis granulosa" are peculiar to tuberculosis. The part of the cords affected is of great importance for diagnosis; for it is especially here that the rule holds good that syphilis attacks the anterior region, while tuberculosis is most marked at the posterior two-thirds. Isolated lesions on the anterior half of the cords are very rarely tuberculous, but the converse does not hold good to the same extent, for syphilis may produce ulcers about the vocal processes while the rest of the glottis is unaffected; cicatricial thickening about the anterior commissure is fairly common in syphilis and very rare in tuberculosis. A plentiful formation of scar-tissue is apt to result from syphilitic lesions and may produce a web across the glottis. Tuberculous ulcers, as I have said already, have very ill-defined edges, so that their exact limits are difficult to determine, there is no surrounding zone of infection, and the base is covered by pale speckly granulations; syphilitic ulcers, on the other hand, have sharply-cut edges, surrounded by a very definite hyperæmia, and the base is smooth and flat. In addition to the laryngoscopic appearance, other points will aid the diagnosis. Thus the character of the voice is very important, and the diagnosis may sometimes almost be made from this as soon as the patient enters the room. The hoarse voice of tuberculous laryngitis is a weak one, and the vocal effort is small, as opposed to the more energetic and harsher "raucous" voice of syphilis where the waste of air is obviously considerable. In syphilitic laryngitis, lesions may often also be seen on the fauces, palate or pharynx, and such are very rare in tubercle. The history is, of course, of some value, and more especially in relation to the duration of the symptoms; a patient with a history of hoarseness for several years, who has only a small lesion—such as localised ulceration—of the cords, more probably owes his troubles to syphilis than to tuberculosis.

The following case, which I saw recently, illustrates some of these points very well.

An unmarried girl, æt. 25, was sent to my outpatient clinic by the physician. She had undoubted phthisis, and had been hoarse for four weeks. There were no external signs of syphilis, and no reason whatever to suspect it, except that the voice had a peculiar rough, grating quality. The mouth and fauces were healthy; both cords were uniformly reddened, and on each, at the junction of its anterior and middle third, was a minute ulcer with a smooth yellow base and sharp edges surrounded by a small but definite zone of infection. These points were sufficient to establish the diagnosis of syphilis, although no history could be obtained and there were no other signs of the disease. I gave her mercury, and in a week the ulcers were nearly healed without local treatment, and in another fortnight the larynx was normal.

A small number of cases of tuberculous laryngitis occur in elderly people, and when the lesion is chorditic in type the resulting hoarseness or loss of voice may give rise to a suspicion of malignant disease which may be extremely hard to disprove. Epithelioma is most common on the vocal cords and appears here—(1) as a warty growth, (2) as a diffuse infiltration, or (3) simply as a unilateral

congestion, it is rare under forty years of age, and is seldom found on the cords in women. Only the rare tuberculous tumours imitate the warty form, but the other two may be very similar in appearance to the type of tuberculosis attacking one cord; however, in the latter affection, the disease is less often absolutely confined to one cord without any lesion of any other part of the larynx. Early and marked loss of mobility, and a heavy delayed movement or "dragging" of the cord, are very suggestive of malignancy, as is also a dirty-white opaque appearance of the growth. The diagnosis

FIG. 1.

is not often difficult, but that it is so at times the following case, recorded by Lake, will show:—

The patient, a man, æt. 51, was seen in June, 1898. He had had a cough during the winter, and had suffered from gradual loss of voice for six months before. The right cord was thick, swollen

FIG. 2.

and greyish-white; later there was immobility of this cord, and the vocal process became prominent and reddened. The case was thought to be probably malignant, exploratory laryngotomy was suggested but refused. Six months later, a portion

of the growth was removed and examined, and the report sent to Dr. St. Clair Thomson, under whose care the patient then was, ran as follows:— "The growth is decidedly suspicious, containing a mass of epithelial cells; but it is impossible to give a definite opinion on so small a piece of ma-

terial, the relations of which to the deeper structures are unknown." Early in 1899, tubercle bacilli were, for the first time, found in the sputum; and the patient died, in June, 1899, of pulmonary phthisis.

In the third common form of this disease, the

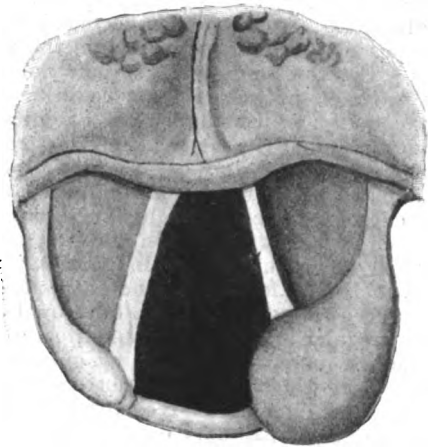

FIG. 4.—Syphilitic disease (tertiary) of left arytenoid and ventricular band.

FIG. 5.—Early syphilitic ulceration (secondary) of vocal cords.

FIG. 6.—Pachydermia laryngis.

interarytenoid region is principally affected; and the lesions often closely resemble those of the pachydermatous form of chronic laryngitis. Pachydermia laryngis, more or less marked, is very common in consumptive patients; Gougenheim, indeed, believes that most cases of pachydermia

are due to tuberculous infection. Pachydermatous thickening is often seen in the posterior commissure in cases of chronic suppuration of the accessory sinuses of the nose, and I believe that the irritation of the sputum from phthisical lungs may produce the same effect, without there being of necessity any infection of the larynx by the tubercle bacillus. Pachydermia affects chiefly the cartilaginous glottis as far forwards as the vocal processes; the thickenings are symmetrical, and begin in the angle between the arytenoid and the posterior commissure, usually leaving a depression in the middle line of the latter; they are regular in arrangement, firm, and of an opaque white colour, and are smooth, or show only a finely-crenated edge like a cock's-comb; small erosions may be seen, but true ulceration does not occur. On the other hand, tuberculous infiltration in the interarytenoid space looks soft, and has a peculiar semi-translucent appearance; the outgrowths are markedly irregular and often asymmetrical; they are frequently merely the edges or granulating base of an ulcer which, seen foreshortened in the mirror, may be difficult to recognise. Distinct ulceration and large papillary excrescences in this region are practically diagnostic of tuberculosis. Sometimes, instead of an irregular mass of granulations, a single papillary outgrowth is found; this is also very characteristic of tubercle, for true papillomata hardly ever occur in this region alone, or on the posterior third of the vocal cord; I have found giant-cells in the base of such a growth after removal.

From lupus, the diagnosis is in reality not difficult. It is seldom primary in the larynx, the lesions being also to be seen on the face and palate. The characteristic nodules are always present; the colour is a rather deep red; if ulcers are present they are well-defined with a dry indolent base, spreading slowly in one part and cicatrising in another, and forming a large amount of scar-tissue. The disease has a marked predilection for the epiglottis, and pain is absent or very slight.

The diagnosis from leprosy also presents no difficulty. In this disease, the skin is always affected as well; the characteristic appearance of the larynx is that of rounded knobs, firm and not translucent, of a pale pink colour, looking like skin rather than mucous membrane. There is no pain, the chief symptom being hoarseness, but dyspnoea occurs when the infiltration is extreme.

I have dealt with the subject chiefly from the point of view which most concerns the practitioner, that is, where the patient is known to be consumptive; and it will be seen that the diagnosis, though often easy, is at other times decidedly difficult, but can usually be made by careful attention to detail. When the throat-symptoms are the first to attract attention, the signs of phthisis in the chest, the temperature chart, and the presence of bacilli in the sputum are important points; but it should be remembered that, though the presence of pulmonary phthisis be proved, it does not follow that the laryngeal disease is necessarily tuberculous. Again, the physical signs in the chest often become masked to an extraordinary extent when the larynx is affected.

When the larynx is attacked primarily, or very early in the course of the pulmonary disease, the affection is apt to take on atypical forms; for

instance, tuberculomata and thyroid perichondritis are comparatively frequent in such cases.

In cases where a rapid diagnosis is urgent, as when malignant disease is suspected, other methods may be employed. The scrapings of an ulcer, or, better, sections of a punched-out piece of tissue, may be examined microscopically and stained for tubercle bacilli; cultures may be made from such material, or a guinea-pig may be inoculated.

The use of Koch's tuberculin has been advocated, and is no doubt of value, in the diagnosis of obscure cases. In adults, 1 milligramme is injected; if the patient be tuberculous, the temperature should rise in ten or twelve hours to 102° or 104° F. The larynx, if affected, will show a local reaction. If there is no reaction, 5 milligrammes should be injected two days later; and 10 milligrammes may be given after a further similar interval, and repeated once again. If the result is still negative, tuberculosis is disproved.

In view of the good results obtained by the active treatment of tuberculous laryngitis in its early stage, I hope that more careful attention will in future be given to its diagnosis, before urgent symptoms attract the notice of patient and doctor; for then the disease is too often advanced beyond the reach of curative treatment.

A PLEA FOR THE NERVE ORIGIN OF CANCER.

BY ROBT. HUGH HODGSON, M.D.

THE rush to discover the specific microbe of cancer seems to me to be very much like a maid turning over and marvelling at the cinders under the grate, and trying to discover how they made the fire. I think it far more probable that cancer is of nerve origin and that any specifically shaped bodies which may be attributed to it are the result of the disease and not its cause. The reasons for looking upon cancer as of nerve origin are numerous, and I think more feasible. Let me, then, for argument's sake, call cancer a nerve disease with local manifestations. No one will deny that cancer is more frequent in the latter part of life, the time when human beings have less reserve nerve energy. Cancer is more common where there is transitional tissue, with its less typical characteristics, and where the nerve direction is dubious as to what type to assume. It is certain that all tissues of the body are controlled by nervous influence, whether histologists are able to demonstrate the existence or otherwise of nerve elements therein. That cerebral disease may and does cause disease in every structure of the body without any necessarily known continuity of nerve tissue is acknowledged, and it may reasonably be assumed that the various tissues of the body are designed and controlled by nerve influence. The fact that sarcoma, a disease nearly allied to cancer, occurs mostly in the young at a time when nerve energy is supposed to be at its best, does not detract from the value of age as an element in the argument that cancer is of nerve origin, but rather strengthens it, for in sarcoma we find an uncontrolled growth more nearly simulating normal tissue, whereas in cancer the growth is more of a degenerate type, due to age decline of nerve vitality. In sarcomatous subjects we may generally detect a want

of sharp delineation of features and form due, as I submit, to deficiency of nerve influence, although the patient may be young. Injury to a part interferes with the nerve control of that part, and long arrest of due nerve control permits growth undestined to serve any special purpose and lacking conformity with any typical tissue. With youth there is more regenerative power, hence we have generally sarcoma in youth and carcinoma in advancing years. The increase of cancer in the present day points to its nerve origin, for now it is necessary to make greater calls upon the brain and nerves generally which, with their consequent diminished reserve store of energy are less able to resist long irritation. People cannot move more quickly, be constantly on the alert to take advantage of an opportunity or to avoid a danger without a greater expenditure of nerve energy. Women suffer more frequently than men by reason of their being more subject to exceptional trials at times when their nerves are fairly exhausted. In other words so long as the part, or that immediately adjoining, is continued to be nourished by the circulation, so long will growth go on and so long as the nerves of that part maintain their functions accurately, so long will that growth be controlled, shaped, and adapted to the special purposes of that part, and conversely when the nerves of a part have become by long continued irritation exhausted or paralysed, so in proportion to the amount of injury will be the unrestricted and purposeless growth. The difference between sarcoma and cancer may be explained by the better circulation of the young. The course of pathological research would appear to be in the chemical analysis of healthy nerve structures, and comparing their elements both quantitative and qualitative with those of nerve tissues in the immediate neighbourhood of, in the near, and at a distance, from the disease. The treatment would naturally be in the direction of increasing the store of nerve force rather than in excitation and exhaustion of what little the patient may have. Removing him from depressing surroundings and encouraging him with the hope of possible arrest of his disease. The consideration whether warm climate is not preferable to cold, the amount and quality of his food; the study and exhibition of those drugs which supply food for nerve centres.

OCULAR THERAPEUTICS. (a)

By SYDNEY STEPHENSON, M.B., F.R.C.S.E.

LECTURE I.

THE general advance in therapeutics that has marked the last few years has been shared in by ophthalmology. It may, indeed, be claimed that in some respects the latter science has led the way, more especially with regard to the principles underlying the local application of remedies. Thanks to the strides of synthetic chemistry, a host of new remedies has been introduced, and although some of these products have not withstood the fire of destructive criticism, yet others have taken a permanent place in the arsenal of therapeutic remedies. There is no organ in the human body better adapted for experimenting with remedies than the eye, since the superficial parts, as the conjunctiva and the cornea, the iris and the crystalline lens, can be kept under close and constant supervision. Not only have new remedies been discovered, but novel methods of applying the older agents have been introduced, as

witness the intravenous injection of the soluble salts of mercury.

In the course of the following remarks I shall deal mainly with such things and methods as I have myself used. I have no sympathy with those who look askance at the newer pharmacology. On the contrary, I am convinced that it is the bounden duty of all in a position to do so to try new agents, to endeavour to separate the wheat from the chaff, and to complete their work by publishing with candour results, be they good, bad, or indifferent. "Surely every medicine," said Francis Bacon, "is an innovation; and he that will not apply new remedies must expect great evils." "A froward retention of custome," he continues, "is as turbulent a thing as an innovation; and they that reverence too much old times, are but a scorn to the new."

My subsequent remarks may be considered under two heads:—First, local remedies—that is to say, such as are applied directly to the eye; and secondly, general remedies, including general anæsthesia, X-rays, radium, serum- and organo-therapy, and the treatment of certain diseased states, as syphilis and rheumatism, that are not infrequently associated with affections of the eye.

I. LOCAL REMEDIES.

It is a matter of familiar knowledge that remedies are applied to the eye in several different ways—as, for example, in liquid, ointment, or powder form. Moreover, as will be explained later, they are nowadays often injected beneath the conjunctiva.

When a drug as atropine is dropped into the eye, dilatation of the pupil is soon observed. By what mechanism does this come about? That the remedy does not act through the circulation is shown by the fact that if it did so it would, when placed in the conjunctival sac of the eye, dilate both pupils. The drug, as a matter of fact, acts by the atropine finding its way by diffusion into the aqueous humour, and thereby acting directly upon the tissues, vessels, and nerves of the iris. The truth of this observation is attested by a famous old experiment. If atropine be employed to dilate the pupil of a dog's eye, and some of the aqueous be withdrawn by means of a syringe, this liquid when placed in the eye of a second dog will dilate the pupil. Remedies which act upon the internal parts of the eye, therefore, when dropped into the conjunctival sac, do so by a process of imbibition, and, as we shall see directly, this process may be hastened by certain remedies, particularly by adrenaline and cocaine. Of the conditions which interfere with the imbibition of fluids from the conjunctiva two stand prominently forward—namely (1) increased vascularity of the surface blood vessels, and (2) increased intra-ocular pressure, or "tension," as it is usually called. A good example is acute glaucoma, where in addition to being congested, the tension of the eyeball is materially raised. To endeavour to render such an eye anæsthetic by dropping cocaine into the conjunctival sac as a preliminary to the performance of an iridectomy would be a sheer waste of time, a fact recognised by every practical surgeon. Hence, the operation in question is seldom attempted under such circumstances without the administration of a general anæsthetic, as chloroform.

Some remedies, as antiseptics and astringents, act directly upon the superficial structures of the eye, and this is equally true whether they are applied as liquids, powders, or ointments. Ointments compounded with vaseline and lanoline present certain advantages, especially when the eye is reddened or waters freely, since they keep the remedy of which they are the vehicle longer in contact, as it were, with the parts on which it is desired to act.

Of late years, more especially in France, attention has been paid to the advantages of employing oily collyria—that is to say, the solution of alkaloids, not in water as is usual in this country, but in oil of various kinds. The medium recommended by Dr. Scrinii, of Paris, is olive oil, although I have found that most

(a) Lectures delivered June 1905, at the Polytechnic, London.

patients upon whom comparative trials are made express their preference for sesame oil. Castor oil may also be used. In this connection it must be borne in mind that the alkaloids themselves, whether atropine, cocaine, or others, must be employed, since the salts of the alkaloids, although freely soluble in water, are but little soluble in oily menstrua. Before the oil is used to dissolve the alkaloid it must be carefully cleansed and sterilised. There are various ways of doing this, but the plan recommended by Delacour is perhaps the best and simplest that can be adopted. It is as follows:—the oil is first well washed with half its volume of strong alcohol, for the purpose of freeing it from fatty acids, and it is then decanted, and, if necessary, filtered. Lastly, it is sterilised by being boiled heated to a temperature of 120° in a sand bath for half an hour. The outstanding advantages of oily collyria are three in number:—(1) they may be kept for many months without undergoing change; (2) they furnish a most unfavourable medium for the development of micro-organisms or moulds; and (3) they produce no irritation when dropped into the eye. It has also been claimed (4) that they fail to set up dermatitis in cases where the same alkaloid dissolved in water has done so (*Ophthalmoscope*, 1905). At all events, oily solutions of atropine and of cocaine offer considerable advantages to country practitioners who in the ordinary course of things must be provided with the several agents, even although they may seldom be called upon to employ them.

There is, as I have said, an important way of applying liquids so as to reach the interior of the eyeball, and that is by injecting them beneath the conjunctiva—the so-called subconjunctival injection, for the popularisation of which we are mainly indebted to Dr. A. Darier, of Paris, the therapeutic leader of our speciality. The principle upon which they are based is a sound one, *viz.*, always to apply the remedy as near the focus of disease as possible. This important principle is now becoming widely recognised in general medicine, as witness the injection into the tuberculous lung of guaiacol, and of the salicyl compounds into the blood-stream of those suffering from acute articular rheumatism.

Subconjunctival injection has received more attention abroad than in this country. Many striking cures have been reported. Its actual position, however, in the treatment of disease has not yet been clearly defined, although it has been on trial for upwards of ten years. The most varied substances have been employed for the injections, but the chief are corrosive sublimate, cyanide, or biniodide of mercury, potassium iodide, sodium chloride, hetol, iodipin, and Poehl's physiological salt, which represents the osmotically active constituents of human blood. It seems probable that the precise agent employed is not so important as the liquid menstruum, for it is difficult on any other assumption to explain the cure of a given disease by using several different remedies. It is not quite clear yet how subconjunctival injections act, although it is likely that the irritation they produce causes an exudation from the vessels of the eyeball rich in albuminoids and protective substances from the blood, with the consequence that the aqueous humour becomes strongly hæmolytic.

Indications.—The injections may be employed in many different affections of the eyeball, particularly in those that are scarcely touched by the more usual methods of medication. At the same time it is necessary to insist upon the fact that the method is not one to be adopted without definite indications or in cases that are likely to yield to simpler measures. After all, the injections entail considerable trouble and time on the part of the surgeon, and call for some little fortitude on that of the patient. They are, therefore, not to be adopted without care, thought, and consideration. The indications for subconjunctival injections may be briefly put as follows:—To produce a sepsis in infective ulcers of the cornea, notably when accompanied by pus in the anterior chamber of the eye (hypopyon); to exert a specific action upon the lesions in syphilitic

choroiditis, retinitis, and, more rarely, irido-cyclitis; to promote absorption in the choroidal lesions of high myopia; to influence desperate cases of sympathetic ophthalmitis; and, lastly, to help in the absorption of the subretinal exudation of detached retina. There is still another indication, and that is in the corneal opacities left by an attack of keratitis, interstitial or otherwise, where subconjunctival injections render considerable help.

The injections have recently been employed with a view to clearing up the opacities of cataract, incipient or advanced. As yet it would be premature to say anything very definite about the method, although no harm can be done by glancing briefly at what has been accomplished in this direction. A Madrid surgeon—D. Verdereau (*Archivos de Ophthalmologie Hispano-Americanos*, October and November, 1904) produced cataract experimentally in rabbits, and then endeavoured to clarify the opaque crystalline lens by the direct injection of a solution of potassium iodide into its substance. The opacity was found to diminish, but, unfortunately, the experiment could not be followed to a conclusion, because severe inflammation came on in the eyes thus treated. In a second series of experiments, he employed subconjunctival injections of the same solution, and found that a distinct effect was produced. Verdereau next applied his experimental results to patients affected with senile cataract. One patient alone had the courage to submit herself to a full course of injections, but the results obtained in that case were truly remarkable, since her sight improved from one-sixth to two-thirds, while the lenticular opacities disappeared step by step with the improvement in sight. Verdereau found a definite improvement in several other patients, even although many of them underwent a single injection only. My own personal experience in this matter may be stated in a few words. During the last three years I have treated by subconjunctival injections several patients who were suffering from choroidal lesions and lenticular opacities. *Pari passu* with the improvement in the choroiditis I have observed lenticular opacities become smaller and in two cases disappear altogether. These experiences encourage me to hope that we may some day be in possession of some remedy that injected beneath the conjunctiva will cause the absorption of lenticular opacities. What is at present a scientist's dream may one day become converted into a sound, a substantial, and a salutary reality.

The Technique of subconjunctival Injections.—The only instrument needed is a small syringe, Pravaz or otherwise, capable of ready sterilisation. Some surgeons introduce a speculum between the eyelids and keep the eyeball in place by means of fixation forceps. This can be necessary only in intractable patients. In young children, the injection is best made after the administration of ethyl chloride. Local anaesthetics, of course, are useless in such young subjects. The conjunctiva is rendered insensitive by means of a drop or two of cocaine (2 per cent.), holocaine (1 per cent.), or stovaine (4 per cent.), the upper lid is raised, and the patient desired to look well down and in. The needle (which should be very sharp) is introduced obliquely beneath the conjunctiva which covers the upper and outer part of the eyeball, between the insertions of the superior and the external rectus muscles, as near the equator as possible. The fluid is then slowly injected beneath the conjunctiva, which rises like a bleb. The needle is then withdrawn, and the little operation is complete. In sensitive people or in those not accustomed to the injection a pad and bandage should be applied and kept in place over night. Pain, chemosis, hæmorrhage beneath the conjunctiva, and swelling of the eyelid may follow the injection, results that depend upon several factors, of which the most obvious are the individual reaction of the patient, the position where the injection is made, and the nature and amount of the liquid employed. The pain produced is perhaps the most serious drawback to these injections, more especially in private practice. But, as

pointed out by Darier, pain may be minimised or altogether done away with by adding to the solution for injection a few drops of 1 per cent. or 2 per cent. cocaine—that is, di-para-anisyl-mono-phenethyl-guanidine-hydrochloride, to give the substance its full chemical title. Recent investigation by Scrin (Arch. d'Ophthalmologie, June, 1905) indicate that the new local anæsthetic, storcise, may be applicable under similar conditions;

One objection urged against subconjunctival medication is that a cicatrix may be produced between the conjunctiva, on the one hand, and the subjacent sclera, on the other. This is doubtless true if the liquid be injected close to the cornea, but not if practised, as it should be, as far away from the cornea as possible. It is not a little curious that Dr. Deschamps has recently (Rev. Gen. d'Ophthalmologie, May, 31st, 1905, p. 222) proposed to avail himself of the production of scar tissue with the idea of so modifying the curvature of the cornea as to correct any regular astigmatism that may exist. For this purpose he proposes subconjunctival injections of sodium chloride at the extremities of the most convex diameter of the cornea, and he claims that by these means it is possible to correct as much as 2D. of astigmatism.

The following rough classification of the local remedies to be now described will render the subject simpler to follow:—

(1) Antiseptics. (2) Mydriatics. (3) Myotics. (4) Anæsthetics and analgesics. (5) Miscellaneous remedies.

I. ANTISEPTICS.

One of the oldest and most efficient antiseptics in eye-work is silver nitrate. Its virtues in that direction were found out by ophthalmic surgeons long before the genito-urinary specialists familiarised themselves with its qualities. "I have sometimes alarmed other practitioners," wrote William Mackenzie, in his famous "Practical Treatise on the Diseases of the Eye," published in 1854 (fourth edition), "by proposing to drop upon the surface of an eye highly vascular, affected with a feeling as if broken pieces of glass were rolling under the eyelids, and evidently secreting puriform matter, a solution of lunar caustic; and I have been not a little pleased and amused at their surprise when, next day, they have found all the symptoms much abated by the use of this application."

In superficial inflammations, which are nearly invariably due to the action of various micro-organisms, silver nitrate has yielded the best results. In bacterial invasions of the conjunctiva, above all, it was until recently indispensable.

The agent, however presents several drawbacks of a somewhat unpleasant nature. These are mainly, if not entirely, due to the nitrate salt with which the silver is combined. I have unfortunately witnessed several accidents, some of a most serious nature, from silver nitrate. For example, a nurse at one of the large Poor-law infirmaries was instructed to apply solid copper sulphate to the eyelids of a child suffering from trachoma. Instead, she rubbed the lining of the lids with pure lunar caustic, with results that may be better imagined than described. When I saw the patient a few hours after the injury one cornea was converted into a greyish slough, and the sight of that eye was practically abrogated. It is gratifying, however, to note that the sight eventually rose to 2-3 normal. Another case fell under my notice a few years ago in the person of a little boy, æt. 9. According to the history, about six weeks before, a somewhat heroic operation for trachoma had been performed upon the lad's eyes. Chloroform had been administered, the trachoma-growths removed with silver nitrate, and the eyes then irrigated with a solution of common salt. The palpebral conjunctiva, when I examined the child, was traversed with cicatricial bands, the lower lids were more or less adherent to the eyeball, and about two-thirds of one cornea was occupied by a curious, greyish-yellow deposit, much like the one spoken of in the case above. V. 1-30 normal. Eventually sight rose to $\frac{1}{2}$ normal. Here are brief details of another

case where I myself actually produced a silver opacity of one cornea! A little girl, æt. 4, was under my care on account of ulceration of one cornea, which refused to yield to the ordinary remedies. The intense photophobia induced me to apply, under ethyl chloride, lunar caustic to the ulcer. The consequence was that, although the ulceration was cured, yet its former site was occupied by a dense, slightly-raised, greyish-white deposit, lying beneath the corneal epithelium. Otherwise the eye was free from redness or irritation. An attempt to scrape away the deposit resulted in opening the anterior chamber and the formation of an adhesion between the iris and the cornea, which had to be liberated later by incision. I could quote other instances of more or less severe injuries to cornea or conjunctiva, but enough has been said to show that silver nitrate is an agent which should be employed carefully, if at all, in cases of distempered eyes.

The other drawbacks of silver nitrate include discomfort, irritation, and actual pain, want of penetration, liability to produce local staining, so-called "argyrosis," and in many cases eschars of the mucous membrane. To be quite candid, the fact is that silver nitrate, although invaluable in the hands of those who have learned how to use the remedy, is apt to become a somewhat dangerous weapon if employed without due experience, skill, and discrimination. The knowledge of this fact has led chemists to endeavour to find an agent that shall possess the antiseptic powers of silver nitrate without its undesirable qualities. It has become widely recognised that the clinical value of a silver compound depends upon the amount of contained silver, and that this is modified, often in an undesirable direction, by the other chemical constituents of the salt. The ideal agent, according to Fraenkel, must fulfil the several requirements of not coagulating albumen or of precipitating sodium chloride, of solubility in water, and of not producing pain or of setting up any irritation of the eyes (*Ophthalmoscope*, March, 1904). The list of agents that fall more or less into line with these requirements is a long one, but I shall discuss only protargol, largin, and argyrol, since I have employed the agents named upon a very extensive scale in the treatment of diseases of the eye. A few words of description may be devoted to each product.

Protargol.—This laboratory product contains 8.3 per cent. of metallic silver. Its watery solutions are stable. It is, however, essential that they should be prepared with cold water, since heat causes an irritating by-product to appear, and this may give rise to pain when the protargol is applied to an inflamed eye. The solution is to be kept, like all silver preparations, in amber coloured bottles.

Protargol is now widely employed in external inflammatory affections of the eye, such as blepharitis, acute and chronic ophthalmia, and lacrymal disease. As a lotion for acute catarrhal ophthalmia, a 5 per cent. solution may be used as an eye wash three or four times a day, and the same solution, or a weaker one, in cases where the lacrymal sac is suppurating. In ophthalmia neonatorum, particularly when the gonococcus is the cause (about one-half the cases) something stronger is called for. The conjunctiva may be brushed one or twice a day with a 50 per cent. solution, the eyes being kept clean in the meantime by the frequent use of a 2 per cent. to 5 per cent. solution. Upon the whole, this is one of the best treatments for ophthalmia neonatorum with which I am acquainted.

Has protargol, then, no drawbacks as regards the eye? It now and then causes some little pain, but never anything like that following the application of even a weak solution of silver nitrate. It is possible, as already hinted, that these discomforts may be connected with an incorrect way of preparing the solution. The great disadvantage of protargol, to my mind, is the undoubted fact that it tends to an even greater extent than silver nitrate to cause indelible staining of the parts to which it is applied. It is this most undesirable quality that has induced me to look in

another direction for the ideal silver substitute. At the same time, there can be no doubt that, clinically, protargol is an active and efficient agent, and one that can never harm the cornea in whatever strength it is employed.

Largin.—This product contains 11.10 per cent. of silver combined with protalbin. It is soluble in water, and may be used as a 10 per cent. solution in the same class of cases as protargol. In gonorrhœal ophthalmia, however, it is, in my experience, nothing like so efficacious, whereas in acute catarrhal ophthalmia—the “blight” of the London poor—it is a veritable specific. It seldom causes pain or other discomfort. Like protargol, it may discolour the conjunctiva if applied for longer than a few weeks, about a couple of months representing the limit beyond which one cannot safely go.

Argyrol.—This, the latest and unquestionably the best of the organic silver compounds, is also known as “silver vitellin.” It does not coagulate albumen, neither is it decomposed by the sodium chloride of the tears. It contains a high percentage of silver (30 per cent.); it is not in the least irritating to the eye; and its powers of penetration are very pronounced. It is extremely soluble in water. It is claimed that argyrol never stains the conjunctiva, no matter in what concentration nor for how long it may be applied. In the light of one patient whose conjunctiva became lightly discoloured after the prolonged use of a 15 per cent. solution, this statement must be modified. It would be more correct to say that argyrol has compared with the other products of silver, very little tendency to stain the conjunctiva. This simple fact at once gives argyrol a superiority over the other salts of silver, organic or inorganic, although it is very difficult to explain, more especially when one recalls the ease with which argyrol is able to penetrate animal tissues. The fact nevertheless remains, and forms an additional argument, if one be needed, for the employment of argyrol upon a wider scale.

My observations with argyrol now extend over a period of about two years, and embrace the treatment of practically every superficial inflammation of the eye. For example, I have used it in all kinds of conjunctivitis, in blepharitis, in phlyctenular conditions of the cornea and conjunctiva, and in diseases of the lacrymal passages. Despite its high ratio of silver-content, I have never yet known it occasion the least pain, irritation, or reaction. No caustic or escharotic action ever follows its use. My experiments have been made with a 15 per cent. solution, except in cases of gonorrhœal ophthalmia, where a saturated solution had been applied. The weaker liquid has been dropped into the eyes by the patient himself two to eight times a day, according to the kind and severity of the inflammation. The stronger liquid has been painted over the exposed conjunctiva, first carefully freed from discharge, once or twice in the twenty-four hours. Almost the first thing that struck me about argyrol was the fact that many patients volunteered the statement that even after the initial application, relief to symptoms was obtained. Indeed, it appeared to act as a direct sedative to the inflamed mucous membrane.

Argyrol, like all silver preparations, tends to stain linen on which it may be dropped, but a solution of potassium iodide speedily removes the marks thus produced.

There are two special ways of applying the new medicament to the eye that deserve to be mentioned definitely, so useful have I found them, especially in hospital work, where cases of the kind abound. There are few more disheartening tasks than to attempt to cure a case of severe ulcerative blepharitis. It is comparatively a simple matter to obtain improvement, but actual cure is quite another thing. In this disease, as in many others, argyrol has rendered me yeoman service. My plan is to rub the inflamed lids vigorously with a pledget of wool soaked in a 25 per cent. solution of argyrol, and to repeat the process, at first daily, and later at longer intervals. This, combined in the more severe cases with occasional cauteri-

sation of the little ulcers lying at the roots of the lashes with the acidum carbolicum liquefactum of the British Pharmacopœia, is the best treatment that I have ever adopted in rebellious cases. The second condition with which everybody must be more or less familiar is eczematous (phlyctenular) conjunctivitis or keratitis complicated with marked photophobia, blepharospasm and watering of the eyes. Such patients under ordinary methods are often “blind” for months together. An ointment containing 10 grains of argyrol to the ounce of vaseline is simply invaluable in this condition, and when the photophobia is very intense, two to four grains of alkaloidal atropine and a similar amount of alkaloidal cocaine may with advantage be added to the prescription. The ointment, whether simple or combined, should be applied two or three times a day. There are few cases even of the most intense and rebellious photophobia that will not yield to this treatment, especially if at the same time the patient's forehead be painted daily with liniment of iodine until the skin becomes sore and slightly cracked. I need say nothing of constitutional remedies, which are called for practically in every case of phlyctenular disease.

General Conclusions as to the Use of Silver.—Nitrat e of silver owing to its irritating, nay, dangerous qualities, and its small powers of penetration, should be used little, if at all, in the treatment of the superficial inflammations of the eye. In severe ophthalmia, such as that associated with the gonococcus, it should be replaced by protargol, 50 per cent., or argyrol, 50 per cent., while in the slighter forms of acute conjunctivitis, such as those caused by the Koch-Week's bacillus or the pneumococcus, argyrol, 15 per cent., may well be used in its place. Weak solutions (5 per cent.) of either protargol, largin, or argyrol may be employed in the secretory purulent affections of the lacrymal sac and passages, and may in those cases with advantage be syringed through the diseased parts, after the duct has been surgically treated, so as to restore its patency. The staining propensities of largin and especially of protargol make me give the preference to argyrol as an agent for general employment. Its recent introduction into practical ophthalmology marks a forward step.

A few other antiseptics should be mentioned, *viz.* chinol, chlorectone, sublamin, sodium hyposulphite, cuprocitrol, collargol, cuprol, mercuriol, formalin, and trikresol. Time, however, precludes me from attempting to describe their individual powers, properties, and uses in ophthalmic work.

Mr. Charles Wray (*Lancet*, April 29th, 1905) has recently described a most effectual way of employing argyrol in that obstinate condition, follicular conjunctivitis. He first empties the follicles by means of pressure between the two thumb nails, and touches the parts with argyrol, 20 per cent. The argyrol is fixed in the tissues by applying a little adrenaline, 1 : 1,000.

(To be continued.)

PREVENTABLE DISEASE IN THE NAVY. (a)

By GERALD SICHEL, F.R.C.S., late Surgeon R.N.

Venereal Disease.—First and foremost among preventable diseases I would put venereal disease, and at once ask myself, Is this disease preventable after all? It is one which has been the bugbear of the naval surgeon for all time, and up to the present we seem to be nearly as far from solving the difficulty as ever. I say nearly as far advisedly, for without a doubt the wider use of iodide of potassium, owing to its lessened price, has done much to prevent the more lamentable results of tertiary syphilis, and it is seldom given to the present generation to see the extensive cases of

(a) Paper read at the Royal Institute of Public Health, London Congress July 1905.

rupia or gummata which were so common, especially among seamen, some thirty years ago.

But as regards the incidence of the disease, neither the abolition of fines among seamen, nor the Contagious Diseases Act, nor higher education among the lower classes, can be said to have done any apparent good. The difficulties with which this question bristles, and deference to Mrs. Grundy, leads venereal disease to be less discussed than it should be by far, to the detriment of both the service and the taxpayer. The army lately appointed a special committee and a special commissioner (an army medical officer) to consider the matter, and no expense was spared to make their report a most valuable one. I should like to see the Admiralty wake up to their responsibility and do likewise.

Scabies.—Scabies is a preventable disease, and although I am not utopian enough to imagine that it will be entirely prevented, I still think that some routine service treatment should be prescribed throughout the navy. This also is a matter for an expert committee to deal with.

The way in which at present "bad-hats" and other loafers conveniently get into hospitals, and thus avoid unpleasant duties, or, perhaps, being drafted abroad, under the cloak of venereal disease or scabies, is appalling. I myself have been "done" time after time, and strongly feel that not special wards, as is at present the case, but special hospitals, and special regulations, should be kept for these cases. To the shore-going practitioner there must seem a wide difference between the two diseases, but the naval surgeon, while recognising that there are many exceptions, quickly learns to appreciate the fact that in the home hospitals at least the majority of the patients in the venereal and itch wards are deserving of but scant sympathy.

Mental Disease.—The amount of mental disease occurring in the navy, although not great, is sufficient to call for attention. Dr. Johnson said that a sea-going life was an unnatural one, and this saying of his has been quoted *ad nauseam*. It applied in his day of masts and yards and uncertainty, but hardly to-day with steam. The fault rather is that although wooden sailing-ships have given place to steel steamships, the regulations for the control of the crews remain much the same. But this is being altered, and all, I think, for the best.

Perhaps the majority of mental cases may be classified under the heading of "General Paralysis of the Insane," and in the navy, as out of it, the causes of this disease may be put down as civilisation plus syphilisation. In other cases alcohol and excessive smoking—particularly cigarette smoking—play a part. Either the over indulgence in these is part of the self control breakdown, or else it is a causative factor; probably the former.

Although it is no part of this paper to deal with remedies, I shall venture to suggest one here. The building-up of the mental side of the organism is far more subtle than that of the physical, and the effects of education, good or bad, are far more lasting.

The critical age of puberty and the next few years require especial advice and watchfulness on the part of those responsible for the welfare of the rising generation. A naval training does not provide for this, and it is difficult to see how it can do so without becoming grandmotherly; my remedy would simply be to impress this point on those in charge of boys and the gun-room. It does not seem much of a remedy, I admit, but if those responsible could be reminded of their responsibility by something tangible, such as a paragraph in the King's Regulations, I feel sure the service would be the gainer.

Phthisis.—The overcrowding and lack of ventilation in ships prove a veritable hotbed for tubercle, once introduced.

The cure here lies in prevention; this means early diagnosis, which is probably best attained by micro-

scopical examination of the sputum. But I am afraid that the navy cannot look to the State for any helpful ideas here. A nation which recognises that tubercle is a rankly infectious disease, and which approves of the building and upkeep of expensive sanatoria—or, worse still, leaves these establishments to private enterprise—and yet omits to make such a disease compulsorily notifiable, is obviously without any medical policy whatever; and such, indeed, is the case. The medical profession as a profession will not assert itself, and the State somewhat naturally, although to its own great detriment, will not recognise the medical profession.

Carious Teeth.—The importance of this fruitful source of disease is well recognised by the Admiralty, who have recently appointed official dental specialists at Chatham, Portsmouth, and Plymouth. It is to be hoped that these appointments will be followed by similar ones in Malta and other naval bases abroad, because it is in tropical and subtropical climates where the teeth seem to "go" easiest, and where defective dentition and digestion are most fraught with dire results. Although these specialists are being appointed, we must not forget the excellent work done in the past by naval surgeons themselves in this branch.

Mediterranean Fever.—This disease, I suspect, will be found ere long to be preventable, the connection with bad sanitary arrangements is so obvious. The geographical limits of the disease reach far beyond the Mediterranean, and the amount of invaliding which it leads to in the navy is appalling. There was an interesting and most instructive paper published recently in the *British Medical Journal* by Surgeons Ross and Levick, and Dr. Eyre of Guy's Hospital is doing sound work, in the hope of producing a preventive serum. As far as Malta—the hotbed of the disease—is concerned, I would like to see a thorough investigation of the underground water-tanks at Bighi Hospital instituted. In my time it was proverbial that a man who came into the hospital with a broken leg invariably went out with Mediterranean fever.

In War-Time.—With the assistance of properly constructed hospital-ships, we shall without doubt be able to add largely to the list of preventable diseases. The Admiralty have acknowledged their recognition of the want of such ships in accepting as a gift from the American nation the hospital-ship "Maine"—I believe I am correct in saying this. This is a notable example of the half-hearted methods of the Admiralty when medical needs are to be considered. If hospital-ships are unnecessary, then the taxpayer should not be burdened with the upkeep of one; on the other hand, if they are necessary, then the British Navy should not be obliged to fall back on the charity of another nation in order to obtain one. One! We want half a dozen, and shall want more in war-time.

Whenever in any particular ship the question of a naval action is discussed, the point arises, "What shall we do with our wounded?" although, by-the-by, the question asked as a routine one by the inspecting Admiral is put not to the doctor, but to the Captain. We have had a great opportunity of adding to our knowledge of this particular matter in the recent heavy naval engagements of the Japano-Russian War, and it is satisfactory to know that the Admiralty have appointed a highly-distinguished Fleet-Surgeon especially to investigate the Japanese methods. This appointment, we may hope, is a token that their lordships are beginning to awaken to their responsibilities in matters medical, and one which redounds exceedingly to the credit of the Medical Director-General.

UNDER the auspices of the National Committee for the establishment of sanatoria a site has been secured at Benenden in Kent, where it is intended to erect an institution for 200 men and women, at a cost of £50,000. An inexpensive class of building is to be erected. The Post Office employes are to benefit by having secured to them a certain number of beds, towards the maintenance of which they will contribute.

British Medical Association.

SEVENTY-THIRD ANNUAL MEETING, JULY 24TH TO 28TH.
[FROM OUR SPECIAL CORRESPONDENT.]

THIRD ARTICLE.

Among the most useful features of the annual meeting of the British Medical Association, the Pathological Museum and the Exhibition must be accorded foremost places. The former is essentially scientific, while the latter is mainly utilitarian. There is need for both. Many have unwisely discouraged and discountenanced the association of commercial enterprise and trade benefit with the chief yearly gathering of medical practitioners. It is clear, however, that the physician and surgeon can be of but limited service unless assisted by the pharmacist and chemist, the instrument maker and manufacturer of sanitary and hygienic appliances. It is, therefore, of the greatest importance that the annual exhibition of drugs and instruments and all material employed in the practice of the healing art or connected with the prevention of disease, should be kept in close alliance with all that makes for scientific advance and ethical progress.

We are glad to be able to record that these two important departments have this year attained to a high level of success, and have admirably demonstrated their right to merit loyal support.

THE PATHOLOGICAL MUSEUM.

The annual collection of pathological preparations was well arranged in one of the large rooms of the technical schools. The excellent catalogue gave reference to 867 exhibits. The Committee responsible for the Museum have admirably fulfilled their task. They arranged that the collection was a demonstration and exemplification of the work of the Sections. Readers of papers and those taking part in the discussions had been invited to place their specimens and illustrations in charge of the Museum authorities. Exhibits had also been gathered together illustrating recent research work. Thus, for example, M. Roux, of the Pasteur Institute, lent specimens of the organism which is alleged to be the cause of syphilis. Another feature of the Museum was the grouping of series of exhibits giving illustrations of pathological lesions affecting the same organ under different conditions; thus an excellent series of preparations illustrated the effect of disease on the bone-marrow. Comparative pathology also found a place. A series of photographs illustrating ovarian and uterine lesions in rabbits attracted attention. It is greatly to be desired that the annual Museum should be thoroughly representative of the best work of the past year and should satisfactorily illustrate the various subjects discussed in the various sections, and this year's well-selected and judiciously arranged collection has gone far towards realising such.

Undoubtedly one of the chief features of the Museum was the admirable collection of Gynæcological preparations. Specimens had been brought from many of the London and provincial museums and many private collections, and illustrated almost all forms of ovarian and uterine disease. There were no fewer than 414 separate exhibits in this Gynæcological Section. Among so many preparations of exceptional interest it is difficult to individualise, but special praise is due to Mr. C. J. Bond's excellent series of photographs illustrating the pathology of the female genital organs.

In the Section of Pathology, Dr. F. W. Mott showed coloured drawings and photographs illustrating trypanosomiasis, sleeping sickness, various forms of meningitis, and microscopical specimens illustrating the fibrillary structure of the neurones of the cortex cerebri prepared according to the new Ramon y Cajal method.

Captain Leonard Rogers had coloured plates portraying the development of flagellated organisms from Leishmann bodies. Mr. Richard Muir exhibited a remarkably fine collection of photo-micrographic transparencies. A very instructive exhibit was that of Dr. W. Sampson Handley, illustrating permeation as

the principal factor in dissemination of mammary cancer.

Dr. K. Grossman displayed a number of beautifully prepared photographs.

Dr. Carnegie Dickson's exhibit of specimens and microscopic photographs of bone-marrow under various pathological conditions was of exceptional interest and value.

Mr. C. C. Hurst exhibited two specimens selected to illustrate Mendel's law of heredity. These preparations were recently shown at the Royal Society's *Conversazione* and now, as then, attracted much attention.

Professor Sims Woodhead and Dr. G. S. Haynes sent an interesting collection of preparations.

Dr. R. H. Bolam displayed a valuable series illustrating aneurism of the left ventricle. Mr. A. Stanley Green had a large collection of excellent radiographs.

Many interesting photographs of dermatological interest were exhibited by Mr. A. T. Bremner, Dr. H. B. Brimacombe, Dr. F. H. Jacob, Dr. H. J. Neilson, Dr. P. Boobyer, Dr. Allen Warner, and others.

In the Section of Surgery, Mr. Noble Smith had a good collection of radiographs. Mr. W. Rutherford Morrison showed a very interesting series of specimens illustrating the pathology of the gall-bladder prepared and mounted by Mr. J. Grey Turner.

Mr. C. J. Bond exhibited a number of specimens taken from the collection of the Leicester Infirmary.

Mr. P. J. Freyer showed a large number of specimens the result of his more recent prostatectomies. Mr. C. Thurston Holland had a most instructive series of radiographs illustrating foreign bodies, calculi, diseases of bone, fractures, and deformities. Mr. James Berry exhibited a series of eighteen thyroids removed by operation.

In the Section of Psychology were many drawings and photographs lent by Dr. James Shaw illustrating forms of mental derangement. Mr. W. A. Potts showed photographs of defective children.

In the Section of Laryngology and Otology, Mr. Albert A. Gray had a collection of preparations of the membranous labyrinth in man and animals. Photographs and drawings were also shown by Dr. H. Smurthwaite, Dr. Jobson Horne, and Mr. C. J. Bond.

In the Section of Army and Navy, Fleet-Surgeon C. Marsh Bradnell had a very interesting exhibit illustrating the penetrative power of Remington, Mauser, Lee-Metford, and other forms of bullets.

In the Section of Tropical Medicine, coloured drawings and photographs were shown by Dr. F. N. Sandwith, Dr. Radcliffe-Crocker, and Dr. J. M. H. McLeod.

Mr. Jonathan Hutchinson, who has for long been a strenuous supporter of museums and has laboured incessantly as a collector of specimens illustrative of clinical medicine, very fittingly provided a most valuable series of drawings.

The Pathological Committee under the Chairmanship of Mr. Charles J. Bond have merited much praise for having so admirably collected and collated much material having a very distinct bearing on present day research.

The Catalogue of 75 pages forms a workmanlike guide and permanent record of considerable value. We could have wished that it had been possible to add an index of exhibitors and exhibits.

KING EDWARD VII.'s Hospital for Officers, 9, Grosvenor Gardens, will be closed from to-morrow (10th inst.) for one month.

Yellow Fever in New Orleans.

SINCE the outbreak of yellow fever there have been 452 cases in New Orleans. It has been decided to request the Federal authorities to take charge of the arrangements for the stamping out of the epidemic.

Plague in India.

DURING the week ending July 1st, the deaths from Plague in India numbered 2,201. Of this number 1,253 occurred in the Punjab, 319 in the Bombay Presidency, 132 in the United Provinces (North West Provinces and Oudh) and 167 in Burma.

The Quatercentenary of the Royal College of Surgeons, Edinburgh.

[FROM OUR OWN CORRESPONDENT.]

Fellowships conferred *honoris causa* (list concluded from our last issue).

Professor Bier, Bonn.—August Bier, was formerly assistant to Von. Esmarch of Kiel, and thereafter Professor at Greifswald. He is well known by his contributions to the physiology and pathology of the blood and has shown the value of hyperæmia as a method of treating tubercle, acute inflammations, and other morbid conditions. He has written on the transfusion of animal blood, and on the treating of fractures by the injection of blood; he originated the method of spinal anæsthesia.

Professor Vincenz Czerny.—Geheimrath Dr. Vincenz Czerny, Professor of Surgery at Heidelberg, is the oldest representative of the famous Bellroth School. In 1871 he was appointed director of the surgical clinique at Freiberg, and six years later was called to the Chair of Surgery at Heidelberg. He is a pioneer in the department of gastro-intestinal surgery, and his writings on the extirpation of the larynx and œsophagus and on vaginal hysterectomy have become classics. I ask you to confer on him the Fellowship *in absentia*.

Professor Franz König.—The present Professor of Surgery at Jena, Dr. König, enjoys a world-wide reputation as a surgeon and teacher. His masterly treatise on surgery has gone through eight editions since its publication in 1876. From 1873 to 1895 he was Professor of Surgery at Göttingen and there obtained his unrivalled experience in tuberculous bone and joint disease. In 1895 he succeeded Bardeleben at the Charité Hospital, Berlin, whence he went to Jena. He has the high distinction of being an honorary member of the German Surgical Society, and I ask you to confer on him the honorary Fellowship *in absentia*.

Professor v. Mikulicz-Raducki.—Among the distinguished German surgeons whom the College had selected as recipients of its honorary Fellowship was Professor Johannes v. Mikulicz-Raducki, of Breslau. He had arranged to come and be our guest here, but within the last few days we have learned of his sudden and unexpected death. I ask you to be allowed to forward to his relatives the diploma he would have received, along with our sympathy for them in their loss.

Professor Dinante, Italy.—The Director of the Surgical Clinique in the University of Rome is one of the most prominent Italian surgeons of to-day. He has made his name famous by many contributions to the surgery of the cerebral nervous system, of which branch of surgery he is a pioneer and acknowledged authority.

Baron Saneyoshi.—It is especially pleasant in our cordial relations with Japan to have the opportunity of offering to Baron Saneyoshi the highest honours of our College. A brilliant surgeon, he has written a standard work on military surgery, and as in the troubled and anxious state of his country it is impossible for him to be present I ask you to confer the Fellowship *in absentia*.

Professor Subbotin.—Among the representatives of Russian surgery Maxim Subbotin holds a very high place as Professor of Surgical Pathology and Therapy in the Military Medical College of St. Petersburg. As he is unable to be present, I ask that you confer the Fellowship on him *in absentia*.

Professor Lennander, Sweden.—The Professor of Surgery in the University of Upsala has written valuable papers on the surgery of the kidneys, biliary passages, appendicitis, and peritonitis, while his work on the sensory innervation of the abdominal cavity enjoys a world-wide reputation.

Professor Kronlein.—The Director of the Surgical Clinique at Zurich and President of the German

Society of Surgeons, after serving in the Franco-German war, became assistant at Zurich. Thence in 1874 he went to assist Langenbeck in Berlin, and was recalled to the Chair he now occupies in 1881. He has contributed largely to our knowledge of cerebral topography, and of the treatment of wounds in general. I ask you to confer on him the honorary Fellowship *in absentia*.

Professor Halstead.—The Johns Hopkins University, founded so recently as 1876, has been the home of many distinguished surgeons, and among those who have added lustre to the School no one stands higher than William Stewart Halstead, who is already an honorary Fellow of the Royal College of Surgeons of England, and to whom no higher compliment can be paid than in saying that many of those trained under him have already attained universal celebrity.

Professor Keen.—It would be difficult to find a surgeon more representative of the great American Continent than William Williams Keen, Professor of Surgery in the Jefferson Medical College, who has been recognised by nearly all the medical scientific societies throughout the world as a distinguished teacher and operator, a writer on cranial surgery, and an authority on diseases of the larynx.

Dr. Howard Kelly.—Among those who have perfected gynæcological technique, Dr. Kelly's place is pre-eminent; he has been a keen, patient, and successful operator and a recognised pioneer in every department of abdominal surgery. He is second to none in his marvellous dexterity in dealing with difficult cases, and has enriched the literature of his subject by works which will remain a permanent monument of his industry and skill.

Dr. Mayo.—Though a comparatively young man, he has already obtained a most extensive and well-earned reputation in abdominal surgery. Among the distinguished American surgeons whom this College delights to honour no one is more prominent in his own country than William T. Mayo, Surgeon to St. Mary's Hospital, Rochester, Minnesota.

Professor McBurney, New York.—There is scarcely any learned medical society on the American Continent of which Mr. Charles McBurney is not a member. He has occupied almost every position of eminence in Harvard University and in New York, and his numerous contributions to surgery, notably to abdominal surgery, have advanced our knowledge in no small degree. I regret that I am obliged to ask you to confer on him the honorary Fellowship *in absentia*.

Professor Warren.—In selecting a representative of Harvard, no more distinguished surgeon than J. Collins Warren, M.D., could have been chosen. He is the author of many valuable papers on surgical pathology and therapeutics, and is joint editor of an international text-book of surgery. It is interesting to notice that his grandfather was the first to employ ether as a general anæsthetic.

This concluded the list of foreign representative surgeons on whom the honorary Fellowship was bestowed, and next in order came the British and Colonial recipients of the honour. As these were naturally better known to the audience, the promoter's remarks about each were comparatively brief. The honorary Fellows Elect were as follows:—

Lieutenant-Colonel Gerard Bomford M.D., C.I.E., Director General of the Indian Medical Service.

Irving Heward Cameron, M.B. F.R.C.S. Eng. (Hon.) Professor of Surgery and Clinical Surgery, University of Toronto.

Arthur Chance, President of the Royal College of Surgeons of Ireland. In presenting him Sir Halliday Croom said: In selecting Mr. Arthur Chance for the honorary Fellowship, the College desires to acknowledge the cordial relations with the sister College in Ireland, and to offer its congratulations to him who occupies the distinguished position of being its President. Late Surgeon-Ordinary to the Lord Lieutenant of Ireland, he is a member of the Council of the Royal Academy of Medicine of Ireland, and holds many hospital appointments in Dublin. He is well known

as the author of many valuable contributions to surgical subjects, mainly in the department of abdominal surgery.

Henry Edward Clarke, C.M.G., President of the Faculty of Physicians and Surgeons of Glasgow, Professor of Surgery St. Mungo's College, and Surgeon to the Glasgow Royal Infirmary. The promoter alluded specially to his services to the nation rendered during the South African War.

Herbert Mackay Ellis, Director-General of the Naval Medical Department.

Sir Thomas Naghten Fitzgerald, C.B., M.D., Honorary Surgeon, Melbourne Hospital, President of the Medical Society of Victoria (*in absentia*.)

Alfred Henry Keogh, C.B., M.D., Surgeon-General Royal Army Medical Corps, Director General Army Medical Department.

Lord Lister, F.R.S., D.C.L., LL.D., Serjeant-Surgeon to his Majesty the King, of whom, said the promoter, it would in this College be an impertinence on his part to do more than mention the name, intimately as he had been associated with Edinburgh. Renowned as a scientific investigator, and hailed as the prince of English physiologists, his services to humanity rendered his name immortal. On account of ill-health Baron Lister was unable to receive the Fellowship in person, and it was conferred *in absentia*.

Alexander McCormick, M.D., Lecturer on Surgery in the University of Sydney,

John Playfair, M.D., President of the Royal College of Physicians of Edinburgh.

John Tweedy, M.D., President of the Royal College of Surgeons, England, who was presented by Sir Halliday Croom as one of the most distinguished ophthalmic surgeons of the day. Besides holding many important positions in the ophthalmological world he has contributed largely to medical history, education, and politics, and has on two occasions occupied the Chair of the Royal College of Surgeons of England.

Frank J. Shepperd, M.D., Professor of Anatomy in McGill College, Montreal, representing the premier colony of the King's dominions beyond the seas.

The ceremony of conferring the honorary Fellowships over, the gentlemen who had received the honour mounted the platform in turn, and briefly acknowledged the courtesy of the College of Surgeons. It was noticeable that most of the replies were couched in English. Professors Eiselsberg, Saxtorph, Lucas Champonnière, Bur, and Lennander all delivered neat and appropriate speeches in the mother tongue of their audience. M. Lucas Champonnière recalled the days when he had studied in Edinburgh under Lister, and said that the honour reminded him of the old friendship between Scotland and France. He offered thanks thrice—thanks from his College, thanks from himself, and thanks from France. Professor Keen in a humorous reply, said he that day disputed the Virgilian maxim, and welcomed, not feared, the gift-bearings of the Scots. Though through his father he was a countryman of Professor Lennander, through his mother he was English, through his grandmother Welsh, and he was now somewhat of a Scot. If he went to Ireland and obtained a little of the brogue, he would be "*Votus, teres, atque rotundus.*"

CONGRATULATORY ADDRESSES.

The final part of the commemoration proceedings consisted in the presentation to the College of congratulatory addresses from various bodies. Owing to the protracted nature of the ceremony, only a few of these were read, the majority being simply handed to the President, who acknowledged them in a word of thanks. The following addresses were presented:—The University of St. Andrews.—By the Dean of the Faculty of Medicine, Professor Reid, and the Principal of University College, Dundee, Professor Yule Mackay. The University of Glasgow.—By the Dean of the Faculty of Medicine, Professor Murdoch Cameron. The University of Aberdeen. By the Dean of the Faculty of Medicine, Professor R. W. Reid. The

University of Edinburgh.—By the Principal, Sir William Turner, K.C.B. The Royal College of Surgeons of England.—By the President, Mr. John Tweedy. The Royal College of Surgeons of Ireland.—By the President, Mr. Arthur Chance. The Royal College of Physicians of Edinburgh.—By the President, Dr. Playfair, and the Treasurer, Dr. P. A. Young. The Faculty of Physicians and Surgeons of Glasgow, By the President, Professor H. E. Clark. The Royal Society of Edinburgh.—By the Senior Vice-President, Professor Geikie. The Edinburgh Medico-Chirurgical Society.—By the President, Professor Chiene, C.B. The Edinburgh Obstetrical Society.—By the President, Dr. N. T. Brewis. The Royal Medical Society.—By the President, Dr. R. J. Johnston. The Merchant Company of Edinburgh.—By the Master, Mr. John Harrison. The Managers of the Royal Infirmary of Edinburgh.—By the Chairman, the Lord Provost.

The whole commemoration ceremony was watched by a large and attentive audience, and was characterized by marked enthusiasm and cordiality. The details had been carefully arranged beforehand, and the whole proceedings passed without the slightest hitch.

In the evening a reception was held in the Royal Scottish museum. It had been originally intended that the function should take place in the College of Surgeons, but owing to the large number of acceptances it was found that the accommodation there would lead to overcrowding; accordingly a change of venue was decided on, which greatly conduced to the comfort of the guests who numbered over two thousand. Among many distinguished persons present, special mention must be made of M. Cambon, the French Ambassador to the Court of St. James's, who happened to be the guest of the Lord Provost of Edinburgh at the time. The earlier arrivals were received by Professor Chiene, in the absence of Sir Patrick Heron Watson, who, along with his daughter, Mrs. Haig Ferguson, acted as host later on in the evening.

OTHER QUATERCENTENARY CELEBRATIONS.

The second day of the Quatercentenary celebrations was given over to a Garden Party in the afternoon and a Banquet in the evening. The former was held in the grounds of George Heriot's Hospital in Lauriston Place, just opposite the Infirmary. The quadrangle, chapel, and board-room with its portraits were opened to the guests, many of whom, though natives of Edinburgh, had not previously had an opportunity of inspecting the valuable portraits and quaint carvings which are to be seen there. Fortunately, the day continued fine, and the gay frocks and millinery made a brave display. About half-past four o'clock, M. Cambon, the French Ambassador, accompanied by the Lord Provost, appeared on the scene. He was received by the strains of the "*Marseillaise*," and then made a tour of the hospital, drinking the immortal memory of George Heriot from the ancient loving cup which is reputed to have belonged to the worthy "*jangling Geordie*" of romance.

After the Banquet, the Loyal Toasts were proposed by the President, and the Corporation of Edinburgh by the Vice-President, Sir Halliday Croom. The President then proposed "*The Honorary Fellows of the College*" in a short speech, and coupled with the toast the names of Professor Fresherr v. Eiselsberg and Dr. Halsted. Professor v. Eiselsberg said that from his master, Billoth, he had learned how much English medical men had helped their science. Amongst the best of them were Edinburgh men. He would not recall them all—Benjamin Bell, Monro, Hunter, Ferguson, and Lyall. But he asked leave to name two—Simpson and Lister, one of whom eliminated pain, the other danger, from operations; the two were the greatest benefactors of the nineteenth century.

Dr. Halsted, in responding, said that during the functions Herbert Spencer's remark that the conferring of honorary degrees was an ill-advised institution, had recurred to his memory, but he was sure that none of the Fellows present would endorse the sentiment.

The hospitality they had received had really been a revelation to Americans. It had taught them in the first place what good manners were. Americans had their ideas of good manners and of what they consisted, but such attention as they had received here was something they knew not of in America. He would not review, as had been so ably done by his predecessor, the names of the great Scotsmen of whom they had heard so much during the past few days, but he should like to ask if it would not be out of order, that they should send a wire to Lister to remind him that they were thinking of him that night, for if it had not been for him, this anniversary would have been of a different character, and, indeed, it would have been impossible to have found men who had contributed enough to the science of surgery on whom they could have conferred the degree of honorary Fellows.

Sir William Turner thanked the guests, in the name of the President, for their presence at the Festival. It would be acknowledged that they had before them a goodly assemblage—one that they might be proud of, met to celebrate the great festival of their 400th anniversary. He then referred to the guilds or corporations which they had in England, Scotland, and Ireland, because these medical corporations were characteristic of the British Isles, and did not exist on the Continent. They were formed in the sixteenth and seventeenth centuries, when professional men came to the conclusion that it would be a wise thing to join themselves together and form guilds. The corporations were corporations which owed their origin not to the State but to the enterprise of members of their own profession. From the efforts of those combines there emerged a system of medical education which gradually perfected itself, a method of testing those systems of education by examination, and, what was more important, a sentiment of professional honour—a code of conduct which should regulate the action of medical men to one another and to the public. Many who were assembled in that hall had come because they recognised the value of that corporate combination. But this motive was not one which could affect their Continental brethren, who had come to meet them in the City because they remembered that all were members of a common profession—of a great profession—and of a profession whose function it was to probe into the causes of disease, to try to get rid of disease, and to put the practice of medicine on a sure foundation. England and France were neighbours in geographical proximity, in thought, and in feeling. They represented the two great nations of Western Europe with whom freedom of speech and freedom of thought were the necessities of life. They welcomed M. Cambon to their board because he was the bearer of friendly feelings toward them. The two nations had noble examples in King Edward VII. and M. Loubet, who had done their best to inculcate friendly feelings between them.

M. Cambon, who replied in French, thanked Sir William Turner with all his heart for the kindly references he had made to his country and himself. A *rapprochement* between France and Great Britain favoured the ideas of liberty and development throughout the world, and so long as he had life he would try to work for a good understanding between the two nations; of such a cause they had no more ardent supporters than King Edward VII. and President Loubet. In the name of the guests he thanked them for their generous hospitality.

Sir John Ure Primrose, Lord Provost of Glasgow, proposed the toast of the Royal College of Surgeons, Edinburgh, in an eloquent speech, in which he quoted as a picture of a good physician the lines on the tomb of Dr. Peter Low, Founder of the Glasgow Faculty, in the Glasgow Cathedral:—"Stay, Passenger, and view this stone, For under it lyes such an one Who cur'd many while he liv'd; So gracious he no man grieved; Yea, when his Physic's force oft failed, His pleasant purpose then prevailed, For of his God he got the Grace, To live with mirth and die in peace. Heaven has his Soul, his corps this Stone, Sigh, passenger, and

then begone." After the President had acknowledged the toast in a few words, the evening was concluded, and with it the Quatercentenary Festival, by the company singing the National Anthem, and "Auld Lang Syne."

Although not actually forming a part of the official celebrations the festivities were suitably terminated by the conferring by the University of the honorary degree of Doctor of Laws on the French Ambassador, and nine distinguished representatives of the medical Profession on Saturday, July 22nd.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, August 5th, 1905.

At the German Society for Surgery, Hr. Czerny Heidelberg, spoke on

PROSTATECTOMY.

He said that the treatment of enlargement of the prostate was formerly carried out by the catheter, but that now prostatectomy had been performed with good results; Bottini's operation did good service in rare cases only; catheterisation always carried with it the danger of infecting the bladder, but life could be prolonged for years by its use. If there was great difficulty with the catheter, the radical operation was indicated, as the operation developed it would be performed at an earlier stage. It was well borne even in advanced age, impotence and incontinence might easily be set up, but these drawbacks were frequently better than the disagreeableness of catheterization. The best results of prostatectomy had been obtained in recent cases, but these could be almost always permanently cured by the catheter *à demeure*. The best indication for the radical operation was old cases of hypertrophy of the prostate along with a healthy condition of the bladder and kidneys.

Which method of operation, the perineal or the transvesical, was not yet sufficiently decided for a pronouncement. By the first a better drainage was assured; the latter was less liable to damage potency. As an operation the perineal was to be preferred. He had operated fifteen times. Two of the cases died, one from sepsis, one on the evening of the operation (cause of death unknown as an autopsy was not permitted). The technique of the operation was still incomplete.

Hr. Kümmell followed on the same subject. He said the radical operation had obtained too little consideration in Germany. He had operated in 114 cases by various methods. Bottini's operation had been performed fifty-one times, but it was not radical, neither was it by any means free from danger as the number of fatal cases showed. With castration, which he had performed twenty-six times, he had obtained really good results, but with two deaths. He had performed both the high and the perineal operation as radical measures in cases in which retention of urine had existed for lengthened periods. The second operation had been performed in cases in which the hypertrophy lay more towards the perineum, the first when it grew upwards into the bladder. The technique was simpler in the high operation; the prostate could often be twisted off by simple rotation after cutting through the capsule. In the perineal operation the urethra had always to be opened. The radical operation should not be performed when there was disease of the kidneys. Advanced age was not a contra-indication; only when the general condition was disturbed; here Bottini's operation was indicated.

Hr. Lexer, Berlin, showed a large carcinoma of the prostate, the neck of the bladder and the adjoining part of the urethra. It was extirpated after making a flap of the abdominal wall, resection of the symphysis, and longitudinal incision into the bladder. Unfortunately metastasis had formed at Poupart's ligament.

Hr. James Israel had had good results with both operations, the suprapubic had the advantage as regarded easiness of performance. But he would raise one technical point: In infection of the bladder closure

of the wound and the placing in of a drain were not sufficient as a depression that retained pus existed below the catheter along with retention of urine. In such cases median prostatectomy was to be preferred when a drain could be inserted. Otherwise both operations were equally good; it was not necessary to keep the patient long in bed.

Hr. Nicolich, Trieste, had performed prostatectomy in thirty-one cases and among them twelve perineal operations with one death. They were all chronic cases with bad retention. The oldest patient was $\text{aet. } 83$, and the result in his case was good.

Hr. Freudenberg, Berlin, would not reject Bottini's operation; it was suitable for special cases. One thing in its favour was that patients submitted to it more readily, potency was not endangered, permanent incontinence after it was rare, and no rectal fistula followed. It was much less dangerous than the others and was quite sufficient when only one lobe of the prostate was diseased.

Hr. Küster, Marburg, had reported six cases of partial prostatectomy in 1889 and the function in all of them was good. In two cases there was injury to the urethra with transient fistula. This operation he had, however, now given up, although it was far less dangerous than complete prostatectomy.

Hr. Riedel, Jena, had for a long time endeavoured to make the partial operation suffice as loss of power over the bladder might follow the total operation. He went from the perinæum and shelled out the prostate with a sharp spoon, taking care not to injure the urethra. He had been quite satisfied with his operation. He had only lost one case from lymphangitis following retention of secretion.

Hr. Hock, Prague, had done partial prostatectomy principally with a view of not injuring sexual function. The result was bad; improvement took place in eight cases, but the patients had had to turn to the catheter again and they had lost their sexual power. The procedure was indicated in recent cases. Bottini's operation was certainly a justifiable one. In a case of carcinoma of the prostate with free bleeding resection of the vasa deferens gave a good result.

Hr. Frank, Berlin, thought suprapubic prostatectomy was the best.

Hr. Kümmell said that he sutured the bladder in the high operation in order to get patients up earlier. After perineal prostatectomy also he allowed them to get up after a few days so that they could breathe better. Partial ectomy would be rarely called for, as it was only rarely that the middle lobe was not implicated.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, July 29th, 1905.

MORBUS BASEDOWII AND RÖNTGEN RAYS.

At the Gesellschaft der Aertze, Stegmann exhibited a few cases of morbus Basedowii, which he had treated with the Röntgen rays according to Görl's method of Würzburg. He told the members he had now applied the Röntgen rays to the thyroid gland in thirteen of these cases with excellent result. Others with recent struma parenchymatosa had the breathing greatly relieved, particularly in elderly females, while the circumference of the neck was reduced, but none of the other phenomena seemed to disappear. He showed the effects on a case that had recurred after an operation for adeno-carcinoma of the thyroid in a female, $\text{aet. } 32$. The tumour, when removed a year previously had all the histological constituents of adenoma and glandular hypertrophy consistent with carcinoma. Besides this, a tumour was located in the supra-clavicular space which gave great pain extending down the right arm. After three weeks' treatment the pain disappeared and the circumference of the neck was reduced 3 centimetres—1.17 inches. In three of the cases one month's treatment dispelled all the symptoms of struma with improvement in the cardiac and pulmonary phenomena, the latter falling from 130 to 80 per minute. The attacks of perspira-

tion became less frequent while the exophthalmus was greatly reduced.

In the discussion that followed, Schiff said that he had been induced by seeing Stegmann's results to try the effects on two cases of struma that had given a good deal of trouble and was now satisfied with the result.

CIRCUMSCRIBED FATTY DEGENERATION.

Among a number of cases which Fuchs exhibited to the members was one with fatty degeneration of syphilitic origin. This was the case of a married woman, $\text{aet. } 29$, who had acquired syphilis through her husband and had twice aborted. During the last two years she had observed herself suddenly becoming large about the lower part of the body, extending over the pelvis to the thighs. The upper part of the body, arms, and lower limbs became gradually smaller, losing all their fat. This decline of the normal fat she observed first in the left breast, which soon extended to the other side, and finally appeared as emaciated. From this emaciation of the unaffected parts, spontaneity and pain on pressure, he differentiated this from Dercum's disease, and designated it circumscribed fatty degeneration.

PROTRACTED TABES.

Another of these cases was an old man, $\text{aet. } 75$, who about the age of 16, had been infected with syphilis. Not till 1850 was any serious symptom to be traced of tabes, but lancinating pains, feeling of a girdle around him, with slight inco-ordination which continued slowly increasing till he recently committed suicide. Before he committed the act he appeared a strong, healthy well-nourished and robust man.

Another younger case of a man, $\text{aet. } 59$, who cannot define the period of infection, and who has now had the lancinating pains for thirty years, was amongst the exhibits. He had also another female patient suffering from progressive tabes since 1890, which had taken the place of an expansive dementia paralytica, which had arisen through sepsis, and probably later supported by the formation of pus.

In the discussion, Schiller remarked that circumscribed adiposis of the lower half of the body was usually due to some nerve disease, probably in this case of Fuchs' to tabes in the lower part of the spinal column, such as the cauda equina. From the patient's history there does not seem to be a single symptom that would point in this direction.

NÆVIS SARCOMATOUS.

Albrecht exhibited a child, $\text{aet. } 10$ months, with a nævus over nates and the right lower extremities, which he found on microscopic examination to have a fibro-sarcomatous consistence, arising also from the deeper sheath of the subcutaneous tissue. Along with this was shown resections of the liver and spleen, taken from a butcher suffering from echinococcus.

INJECTIONS OF CHOLIN.

Exner further reported on his experiments with cholin in the decomposition of lecithin, which had also been produced by the Röntgen and radium rays. In his previous cases he proved it by subcutaneous injections under the skin and scrotum. He now injects direct into the peritoneal cavity and into the mesentery if possible, where the typical change is to be found in the lymphatic glands and spleen of the injected animal after being killed. In the normal gland large numbers of lymph follicles are to be found, while in the animal experimented on the lymphoid tissue has been greatly reduced and the follicles lost. In the spleen the same change is observed. This, he considered was analogous to Heinecke's experiments with the Röntgen rays. For some time past Schlecta has held, with considerable reason, that this change is due to the alkali contained in the cholin which may now be established as conclusive. He pointed out to the members that there was no eschar or searing of the mesentery or peritoneum nor could any particular change be observed in the glands themselves.

Operating Theatres.

ST. THOMAS'S HOSPITAL.

OPERATION FOR IRREDUCIBLE HERNIA OF AN UNUSUAL CHARACTER.—Mr. BATTLE operated on a boy, æt. 8, who had been admitted for an irreducible hernia of some months' duration. The scrotum on the right side was enlarged and the swelling gave an impulse on coughing but was irreducible. The inguinal canal was occupied by a continuation of the swelling. It was rather peculiar in shape, its lower part being rounded and somewhat the shape and size of a man's little finger. The diagnosis, Mr. Battle said, appeared to lie between irreducible hernia consisting of omentum, which was thickened by inflammatory change and adherent to the inner wall of the sac, or the presence of some such structure as the cæcum which had become thickened by inflammatory change. It was suggested, he remarked, that this lump was a tuberculous deposit in a portion of omentum which had become adherent, but in the absence of any abdominal signs of tubercle, such as thickenings or the presence of free fluid, in the absence of a history pointing to intestinal disturbance, this was considered improbable. Moreover, although adherent omentum is the most common cause of irreducibility of hernial contents, it is rare, he pointed out, to find omentum occupying a prominent part in the hernia of a child. At the operation it was found that the irreducible part was due to the cæcum and appendix which had slipped down and become adherent to the parts around. The appendix, which was a good deal enlarged, occupied the lowest part of the sac, passing from behind forwards; in it could be felt a good-sized concretion. It was shut off from the peritoneal sac and covered in by many adhesions; these adhesions were in fact so numerous that the peritoneum forming the lining of the protrusion was not larger than the end of a small forefinger. The whole of this was, however, thickly studded with tubercles. Examination through the internal ring showed a similar condition of the peritoneum within the abdomen. The appendix was clamped, the stump ligatured, and the appendix cut away beyond the ligature, the remains being buried in the wall of the cæcum; the latter was returned to the peritoneal cavity, the sac cut off after ligaturing, and the operation for radical cure completed after Bassini's method. Mr. Battle said that tubercle of the hernial sac was an unusual complication, and it was met with in cases where there was usually no reason for suspecting the presence of that disease. Occasionally, however, something might suggest it. For instance, in one case, Mr. Battle remembered, in which it was diagnosed, there had been a tuberculous epididymitis on the same side as the hernia; even in the case he had just operated upon the tubercle he thought had probably been responsible for the extensive binding down of the cæcum and appendix, although it gave no evidence of its presence before the sac was opened. It would be interesting, however, Mr. Battle considered, to note the effect of the operation on the peritoneal tubercle. In one patient he mentioned where a tuberculous sac had been ligatured, the boy returned some weeks later with an abscess of the abdominal wall apparently tuberculous, but he has not developed any signs of abdominal disease.

The patient made a good recovery and will probably remain without further complication.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 6d. Post free, 5½d.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5 0s. 0d.; Half Page, £2 10s. 0d.; Quarter Page, £1 5s. 0d.; One-eighth, 12s. 6d. Considerable Reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the Publisher.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and Colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 9, 1905.

THE PASSING OF THE MEDICAL PRACTITIONER.

THERE can be little doubt that the average general practitioner of the United Kingdom is going through more than usually bad times. He is called upon to face competition from quarters that should be the last to injure men of his profession, namely, the medical charities, who not only shower their benefits on well-to-do persons, but take their money in payment for services rendered both as in- and out-patients. Then there is the ever-increasing competition of unlicensed quacks, who are permitted to carry on their nefarious practices at the cost of the legitimate and state-recognised medical practitioners. The root of the evil is the apathy of medical men themselves where their own interests are concerned. That fact has been recognised ever since there have been reformers and grievances in the world of medicine. The lawyers have taken care to defend their legitimate practice with stringent laws administered by the Incorporated Law Society, a body that is wealthy, powerful and watchful to the last degree of all outside agencies that may be detrimental to members of the legal profession. Contrast that state of affairs with the brazen piracy that is carried on openly and on all hands by electricians, beauty specialists, cancer-curers, bone-setters, rupture specialists, Christian Scientists, and a host of similar charlatans. The general Medical Council looks on complacently, for its business is not to protect medical men against illegal competition—it is simply to regulate qualified medical men and maintain the Register. Composed as it is by a vastly preponderant majority of representatives of privileged corporations, the Council is not likely to be in touch with the thoughts, wishes, and aspirations of the general practitioner. With a reformed constitution and charter, the General Medical Council might become a tower of refuge and of strength to

the medical profession comparable with the position of the Incorporated Law Society. The first great step towards a better state of things will be to make the Council a representative body. Nor is it easy to understand how men of candour and high position, such as those who now sit on the Council, can cling to a non-representative principle which is an anachronism and a relic of barbarous class administration unworthy of a learned profession. The only explanation possible is that collectively members of the Council accept a position that individually they would hardly attempt to defend. Until medical men help themselves they are likely to remain in their present disadvantageous position. The outside public know little, and care less, for the medical profession as a whole. That attitude is well illustrated by a "silly season" correspondence going on in the public Press at the present moment. Some inspired journalist advanced the proposition that "the doctor's occupation will shortly be gone." That view is supported by the following tokens:—Increased competition for practice. Progress of specialism. Increased medical knowledge of the public. Tabloid medication. Treatment by unqualified practitioners. Swedish methods of treatment. Shortening of the London season. Increased cost of living. Having thus fairly launched his thunderbolt, the next step was to visit a medical agent, from whom he forthwith obtained the column or so of thin literary copy necessary to his purpose. Needless to say, little if any real light was thrown upon the weirdness of the grim tragedy—for tragedy there is—which had originally fired his journalistic instinct. The medical agent's philosophy may be gauged from the fact that he dismissed the item of unqualified practice by the quibble that a man could not practise unless he were qualified. Would that the vast mass of unchecked piracy thus indicated could be disposed of in that quick and airy way. The want of employment was met by the statement that there was a difficulty in finding men to take *locum tenens* work at four and even five guineas a week. This is the sort of stuff which journalists think good enough to foist upon the public where the medical profession is concerned. The underlying moral is not far to seek. It is the old, old story, that God helps those that help themselves, and that the medical profession must look to itself to escape from the nets that have been spread around on all sides. Let us begin with the reform of the General Medical Council.

LONGEVITY.

PROFESSOR OSLER has had to take up the Regius Professorship of Medicine at Oxford under a cloud—the cloud of a joke. We prefer to attribute the ridiculous seriousness with which his *jeu d'esprit* was taken rather to the exigencies of the trans-Atlantic cable than to any obtuseness in our compatriots, but the fact remains that a great many people in Great Britain know Professor Osler chiefly as a man who thinks people are too old at

forty and only worthy of comfortable euthanasia at sixty years of age. There can be no doubt that the distinguished head of the medical school at Oxford will, by the exercise of his characteristic energy, dissipate any misapprehensions that may be entertained as to his own practice in the method of employing his time, and we shall be surprised if from the monastic retreat that he has chosen, Professor Osler does not give forth some of the most mature and brilliant work of his life. But the little joke, even if it missed its point, has set people thinking, and at this time of conferences and annual meetings the subject of longevity has employed the tongues of at least two orators—namely, Sir James Crichton Browne at the Congress of the Royal Institute of Public Health and Dr. Charles Stockton, of Buffalo, at the annual session of the American Medical Association. Both these speakers handled the subject of longevity in the spirit of modern evolutionary philosophy, and both by rather different avenues of approach have arrived at the conclusion that length of years is not only a good thing in itself, but that it is attainable in greater or less degree by human effort. The desirability of living to old age is a question with which medicine as an art does not concern itself, any more than it does with the value that the life of a particular patient may have for the community. A medical man is bound by the canons of his creed to save life, even if it be that of a criminal, and to prolong life, even if it be that of a suicide or hopeless sufferer. So, too, in the larger realm of preventive medicine, the object is to prolong life to the utmost of its natural span. Readers of Cicero's "De Senectute" will probably have long made up their minds that not only has old age its peculiar delights, delights which vary from philosophic contemplation as in the case of Plato to feasting and ostentation as in that of Duilius, but its peculiar utility to mankind, as in the cases of Homer, Hesiod, Pythagoras, and a multitude of others. The dotards—"comicos stultos senes," as they were called by Cæcilius—are for the most part pathological products of misspent or unfortunate adolescence. A hale old age with its varied amusements and quiet pleasures should theoretically be the normal ultimate destiny of a well-laid-out life crowning a good constitution. So that in considering the means whereby longevity may be attained the domain of preventive medicine is sensibly widened to include the whole art of civilised citizenship. There must be assured to the citizen a good constitution to begin with and conditions of environment which give that constitution opportunities to ripen, and protect it from blighting influences. The assurance of a sound constitution was the principal theme of Dr. Stockton's address, and he pointed out that this was a matter of heredity, and therefore that the real start in the search for longevity must come through the application of the laws that govern the science of breeding. It is Lamarckism, pure and simple, to expect that education and hygiene will directly influence the

stamina of the race, for such a supposition connotes belief in the transmission of acquired characteristics; the propagation of a sound stock must depend on the conjunction of sound ancestors. And here we are landed in all the difficulties, social and political, that surround the new science of eugenics. At the same time it must be admitted as the fact that if the normal span of life is, for the bulk of mankind, to be stretched from three score years and ten to Sir James Crichton Brown's sanguine estimate of five score, something in the nature of the prevention of weaklings and the encouragement of the robust must take the place of our present hap-hazard love-making. Then will those further conditions on which Sir James insisted be capable of effecting their maximum good; without selection we fear centenarians are more likely to be numbered by the score than by the hundred. The intelligent rearing and feeding of children, the prevention of epidemic diseases, the provision of good houses, and the promotion of physical development will all aid in the future, as they have all aided in the past towards lengthening the duration of life, and these questions are constantly agitating the minds of hygienists. But Sir James Crichton Browne takes a bold step further when he tackles the psychical aspect of his subject, for he lands his followers in controversial political questions such as that of old age pensions. To rid the mind of care and worry will most surely affect the duration of life to a considerable extent by postponing the advent of arterio-sclerosis, the greatest single life-shortening influence, but we confess that such a proposition strikes at the root of modern existence to a degree that makes us tremble. *Æquanimitas*—we find we have come back to Professor Osler again—can be attained for humanity only by a reversal of all the laws of Nature—a complete subjugation of the cosmic processes—an absolutely perfect civilisation. And then we shall have reached not only centenarianism, but also the Millennium.

Notes on Current Topics.

Undesirable Nursing Home Methods.

IN July last a medical man, Mr. Owen Lankester, wrote to the *British Medical Journal* advocating the drug treatment of chronic inebriety by the hypodermic injection of atropine "or one of its allied alkaloids." In the letter he mentioned the name of Mr. A. W. Jamieson, of 1, Mitre Court, Temple, E.C., presumably a barrister, as a gentleman willing to give further particulars. A circular letter has been sent to us from a correspondent, which we reproduce:—

"25, Cheniston Gardens,
"Kensington, W.

"July 15th, 1905.

"Sir,—The above is the address and telephone No. of the special nursing home for alcoholic cases, referred to in Dr. Owen Lankester's recent letter to the *British Medical Journal*, copy of which I enclose. The course is one of *four weeks*, and I can give you the names of a number of other

medical men who are thoroughly satisfied with the results of the treatment. May I call and give you full details?

"I am, sir, yours faithfully,

"A. W. Jamieson."

This letter contained a reprint of Mr. Lankester's original letter to the *British Medical Journal*. The whole proceeding appears to be unworthy of the dignity of the medical profession. This advertisement of a special treatment in connection with a special nursing home seems to us to be skating with a vengeance over the thinnest of ethical ice. What has the *British Medical Journal* to say in the matter? No drug treatment of inebriety has yet been accredited by the medical profession, nor does there seem the least likelihood of anything of the kind occurring, although many claims for so-called specific remedies have been made both inside and outside the profession—usually outside.

A Judge on Professional Etiquette.

MR. JUSTICE WILLS is well known as a man of sound intellectual balance, who is not afraid of speaking out his mind. At Birmingham Assizes, last week, he commented severely on the medical evidence in an action for damages brought against the Birmingham Corporation. A medical witness attributed an abscess of the breast from which the plaintiff suffered as the result of the accident which formed the basis of the lawsuit. The defence, on the other hand, called Dr. Lucas, of the Birmingham General Hospital, who is reported as saying that to attribute the debility from which the plaintiff was then suffering to abscess was absurd. It is difficult to gather the exact truth from a condensed newspaper report, but clearly an abscess of the breast may be the direct or indirect cause of almost any kind of "debility," immediate or remote. Whatever Dr. Lucas said, his attitude called forth the remark from Mr. Justice Wills that it was to be regretted that a man holding his position should speak in the manner he did of another medical gentleman. We go further, and say that the contradictory "expert" medical evidence given in courts of law constitutes a standing reproach and scandal to our profession. The ends of justice, moreover, are not likely to be adequately served until medical points are settled by a consensus, at any rate by a majority, report of a body of independent skilled investigators.

Robbery Under Chloroform.

WE fear that the Italian correspondent of one of our medical contemporaries must have been caught napping when he retailed to the journal a sensational story of a gang of hotel thieves who rob their victims after anaesthetising them, but this paragraph has been eagerly copied. The *modus operandi* of the gang is asserted to be as follows:—A likely subject for the experiment having been selected, the thieves engage a bedroom next to his in the hotel, and with special instruments perforate

the wall in the neighbourhood of the victim's head. Through this hole thus made a long, fine cannula is passed, and while their innocent prey slumbers whiffs of chloroform are puffed till he is completely anaesthetised. Then the wicked robber forces the door, takes what valuables he fancies, and decamps in the early morning by a "through express." The story with its lurid detail would make a capital plot for a "serial" writer, and we commend the idea to him if he has not already evolved it from that prolific inner consciousness which daily brings forth to an astonished world things old and new. But for medical men we fear it will not "wash." Apart from the improbabilities involved in many of the details, we have yet to see the sleeper who would go through the first stage of chloroform anaesthetisation without a murmur, and though we believe in allowing a good admixture of air when administering chloroform, we hardly think the proportion of chloroform conveyed by a "long, fine cannula" would be sufficient for the purpose. The story reminds us of the chloroforming we have seen on the stage, when the victim of the villain's machinations falls unconscious after his first sniff at the fatal handkerchief. In future we shall expect thieves to arm themselves with nothing less formidable than the Vernon-Harcourt inhaler, if they wish us to believe in their diabolical intentions.

Statistics of Venereal Disease.

It is notoriously difficult to obtain any trustworthy figures to show either the incidence or the mortality in any country of the venereal diseases. The Registrar-General's returns of mortality from syphilis cannot be relied on, for in but few cases of death ultimately due to this cause does the same appear on the death certificate. For instance, in Ireland, in the year 1903, out of 77,358 deaths registered, in only 104 is the cause given as syphilis, and in 14 as gonorrhoea. These figures obviously bear no relation to the actual facts. With regard to the extent to which venereal diseases exist in the living population, it is just as difficult to form an estimate, and the estimates that have been made are more or less guesses depending on individual experiences. Sir William Gowers is reported to have given his opinion that there are half a million people in London alone who have contracted syphilis. There are said to be 150,000 syphilitics in Berlin, and 225,000 in New York, while in France one out of every seven people is said to have the disease. Figures based on admissions to the Army can obviously not be taken as representative of the conditions of the general population, since in different countries the army is recruited from quite different classes of the population. Nevertheless, such figures are instructive, though they show a very wide variability, reaching the highest figures among British recruits and the lowest among German. Out of every 1,000 admitted to the following armies the rates for gonorrhoea and syphilis were respectively, Germany, 27 and 5.5 ;

Russia, 36 and 13 ; France, 40 and 9 ; United States, 73 and 16.8, and Great Britain; 173 and 101. We still seem as far as ever from devising any practical means of preventing the spread of these diseases.

Changes in the Curriculum of Dublin University.

FOR some time various questions regarding the arrangement of the curriculum of the School of Physics in Trinity College have been under discussion, and we understand that a scheme has now been agreed upon which will shortly come into force. Two main objects are stated to be in view—one, more thorough training in the preliminary sciences, and the other, the prevention of undue interference by the course in Arts with that in medicine. With regard to the first point, practical courses in botany, zoology, physics and mechanics are to be added to the theoretical instruction in these subjects. The grouping of the various subjects of the course for examination purposes is to be entirely altered, and we understand that no student will be permitted to proceed to the study of one group until he has satisfied the examiners in the preceding group. With regard to difficulties supposed to arise from the Arts course interfering with medical studies, it is said that greatly increased "professional privileges" are to be granted to students of medicine. If we are not misinformed, it is proposed, in fact, to cause a practical obliteration of the Arts course, allowing students to proceed to a B.A. degree by passing an examination in medicine. Although, of course, there are good points in the scheme, the proposed changes do not on the whole appear to have a tendency to improve either the status of the Dublin degree or the value of the training given in the School of Physics. The earlier part of the medical course is, in Dublin as everywhere else, as the President of the British Medical Association pointed out the other day, already over-weighted, and if any improvement is needed in medical teaching it is on the clinical side. The lightening of the Arts course, on the other hand, is a step which is bound to have the effect of lowering the value, from a social and educational point of view, of the Dublin degree.

Registration for Nurses.

THE Select Committee that have been inquiring into the question of the State Registration of Nurses have now issued their report. A large number of witnesses have been heard, most of whom were in favour of some change being made in the conditions that now exist, though many differed as to what the change should consist in. We are glad to know that the Committee found no evidence to substantiate the assertions, freely made, that illegality, immorality, and scandal were prevalent among untrained women who take to nursing. That a certain number of undesirable characters should masquerade as nurses

is of course inevitable, but the evil would appear to be one of small dimensions. Nevertheless, seeing the changes that have taken place in the conditions of nursing since it became a skilled art, the Committee recommend a central body should be formed to control nursing affairs, without interfering with untrained nurses who do not wish to continue their calling. This central body should, they think, be composed of matrons, nurses, doctors, and representatives of the public, and of the nursing schools, and should keep a register of the names of properly trained nurses. Only nurses so registered should be able to use the description "registered nurse," not a very happy term, we think, and one that might well be altered to something more distinctive and euphonious. Three years' training and a certificate that they have satisfied the authorities of their school as to their proficiency should be necessary before a nurse be registered. Moreover, the Committee hold, and in this one thing every one will agree with them, that nursing homes that supply nurses for the sick or receive patients for treatment should be registered by county or country borough authorities. It will be interesting to see how long it will take before a Bill embodying these suggestions becomes law.

The Uxorious A.M.O.

THE asylum service of the London County Council is developing into a very big affair, and as the demands of the county lunatics increase it needs more and more complete organisation. Hitherto the medical staff of an asylum has consisted of a superintendent and four or five assistant medical officers, and though the interests of institutions may not be seriously jeopardised by changes among the juniors, it is absolutely necessary that the superintendent should have a permanent assistant of experience on whom he can rely when he is sick or on leave. The senior assistant medical officer has consequently become a vital factor in asylum life, and as promotion is slow he often finds himself well on towards middle age before he is selected for a superintendent's post at his own or another institution. As the position of the senior assistant carries with it fair remuneration besides the ordinary emoluments of a resident officer it certainly seems an anomaly that he should be compelled to remain a bachelor, especially as leave of absence from an asylum has to be much restricted on account of the multifarious social duties connected with the institution that fall on his shoulders. The matter has been before the Asylums Committee of the Council for some time, and last week they brought up a recommendation to the Council that the senior assistant medical officers should be allowed to marry. A good deal of opposition was encountered, chiefly on the score of expense, but the proposal was eventually adopted by a large majority. The decision is one which is in accordance with the simplest ideas of justice and prudence, and we hope we shall soon be able to publish a

crop of nuptial announcements in their appropriate columns.

Moist and Dry Air.

WE are so accustomed in these climates to suffer, even in the hottest weather, from excessive moisture in the air, that we usually look to dry heat as the ideal weather for summer. In doing so we are inclined to forget that, though not so unpleasant in some ways as moist heat, yet dry heat has drawbacks of a very serious nature. It is true that very rarely in temperate zones is the atmospheric air so dry as to cause serious annoyance, yet very frequently with our modern methods of heating and our lack of ventilation, indoor air becomes unpleasantly deficient in water vapour. In buildings heated by direct radiation it may happen that the air does not contain more than 20 or 30 per cent. humidity, while out of doors there is most probably 60 or 70 per cent. Such a great variation from the normal must, of course, tell on the human body in some way, and it is natural that the respiratory organs are those that suffer. When one reflects on the great expanse of moist surface in the respiratory tract exposed to the parching of very dry air, one is not surprised that the mucous membrane soon becomes dry and irritable. The result is a very unpleasant pharyngitis, with probably more or less troublesome conditions of the nares and larynx. The best remedy for this excessive dryness of indoor air is, where possible, free atmospheric ventilation through open windows. Where this is impracticable steps must be taken to provide moisture artificially by the rapid evaporation of water with the air supply.

The Price of an Eye.

IN successful actions for damages for injury to the human body, a jury always has considerable difficulty in arriving at a decision as to the proper amount of compensation to be awarded. Apart from the question of the degree or nature of the injury, there are many points of great complexity to be considered. The position of the victim and the possible interference with his means of livelihood and prospects in life furnish the guiding clue in most instances, but it is scarcely to be wondered at that Courts have shown but little uniformity in their decisions. An American contemporary has collected some recent decisions of the higher American courts in cases where the cause of action was the loss of one or both eyes. The lowest compensation granted among the cases quoted was £600 for the loss of an eye, the other being slightly injured; the victim in this case was a porter. In another case a woman who had one eye destroyed in a railway accident obtained compensation to the amount of £1,400, while a young girl, a stenographer, was awarded £2,400 for total loss of sight. A man who had lost both eyes was awarded £1,800, while another, a farmer, for the loss of one, obtained £1,000. It would seem that in America two eyes are proportionately cheaper

than one. This is, of course, quite irrational, as the loss of one eye may not be a matter of great pecuniary importance to the owner, while the loss of two means in most cases a termination of his active career. In this country, if we are not mistaken, a medical student a few years ago obtained a verdict for £2,000 for the loss of one eye.

Rights in Prescriptions.

It is not often that legal luminaries adopt a sympathetic attitude with regard to the claims of medical men, so that it is particularly cheering to see an able and completely satisfactory statement as to the rights of a physician in his prescription made by a judge, even though he be an American. Judge Gaynor, of Brooklyn, in giving judgment in a case which involved the question as to whether a dispenser had a right to alter a prescription, said that a prescription was an order by a physician given to a druggist to supply his patient with a certain preparation. It should, therefore be sent to the pharmacist under seal, and after it had been dispensed should be held by the pharmacist as his warrant for having made up the particular mixture. It should always be accessible to the doctor, but to no one else. "The patient," said the judge, "pays the doctor for what he knows and is able to do for him, at the time of consultation. He does not pay for a visible and tangible prescription itself, or to any knowledge to be derived from it, neither he nor anyone else, now or hereafter, has the slightest right. The druggist who will not stand by the physician in this is not only his own worst enemy, but he is a menace to the doctor and a black sheep in his own profession." We wonder how many occupants of our own bench would, or could, have given so definite and luminous a statement on the plain rights of this plain question.

The Presidential Address to the British Medical Association.

THE Presidential Address at Leicester, delivered by Mr. Franklin, may, for eloquence and thought, take its place besides any of its predecessors, distinguished as have been many of those delivered from the presidential chair. Mr. Franklin points out what he considers three main defects in the education of the student of medicine—deficiency in the sphere of preliminary education, of obstetric medicine, and of practice of anæsthetics. The teaching of obstetrics is, outside Ireland, notoriously insufficient, and the fact is bound to tell, as Mr. Franklin says, against success in general practice. Instruction in the administration of anæsthetics is, we believe, greatly increased in recent years, and there is a satisfactory tendency to regard it as necessary that the student should have at least a good working knowledge of the subject. As for preliminary education, we fear that the tendency of the day is altogether opposite to what Mr. Franklin desires. He looks forward "to the good time coming when all medical

students shall be undergraduates of a university, and shall have to take a degree in Arts." The tendency is altogether to lessen requirements as regards general education, as is perhaps natural with the present overweighted condition of the medical course proper, and even the older universities, such as Cambridge and Dublin, are gradually reducing the Arts education of their medical students to vanishing point.

The Word "Apthous."

THE clinical condition frequently met with in infants' mouths, known as apthous stomatitis, consists in a catarrhal inflammation of the buccal mucous membrane characterised by the appearance of herpetiform vesicles which quickly rupture, leaving minute, yellowish-white ulcers surrounded by a red areola. As far as is known, the affection is non-parasitic, and it is induced by mal-nutrition and those gastro-intestinal disorders incident to the first few months of life. Special forms of the disease, in which the apthous ulcers run together to form large white patches, are prevalent in certain districts, and all the concomitant symptoms, local and constitutional, are correspondingly more severe. The term "apthous" is, however, often applied in a loose way to signify any ulceration of the interior of the mouth preceded or accompanied by small white points or patches. Parasitic stomatitis, or thrush, is wrongly included under this term, for although there is generally a certain amount of inflammatory reaction present beneath the white spots characteristic of this affection, yet there is a tangible cause for the lesions in the *oidium albicans*, the presence of which may easily be demonstrated under the microscope. This variety of stomatitis is far less painful, too, than the ordinary apthous or follicular form. As might be expected, the source of the fungus in thrush is usually to be found in dirty feeding-bottles. At a recent meeting of the Société de Pédiatrie, of Paris, a discussion took place with regard to the use of the word "apthous" in medicine, and the majority of the members considered that the term should only be employed in a subjective sense—*i.e.*, when pain and inflammation predominate. It would certainly be advisable to avoid the word when speaking of true parasitic stomatitis.

Liability for Poisoning.

FOLLOWING as it does on certain recent actions for damages which will be fresh in the minds of our readers, a decision given by Judge Edge in the Clerkenwell County Court on August 2nd will strengthen the hands of those who desire to see greater care given to the question of food supplies. A widow, living at Islington, brought an action for damages resulting from the death of her son against a fishmonger who had supplied him with some eels for stewing, whereby he was afflicted with ptomaine poisoning, from which he died. The Judge, in awarding her £40 damages

and costs, remarked that the case raised most important questions, not only for the defendant, but for all people who supplied food to the public. There was no negligence on the defendant's part, but he must be held to warrant food that he sold to the public as good and wholesome, as was provided for by the Food and Drugs Act and the Sale of Goods Act. In the case in question the deceased had relied on the defendant's expert knowledge to provide him with what was good and wholesome, and therefore he was entitled to expect a trustworthy article. That the defendant had presumably done his best and failed did not prove either a bar to action or a good defence, and the mother was entitled to damages for loss of her son's services. Actions of this kind ought to be brought widely to the knowledge of people, for if all cases of illness caused by food were made the subject of civil actions, food purveyors would soon take special precautions against adulteration and contamination. An epidemic of poisoning that could be traced to an ice-cream vendor, for example, would spell ruin to the purveyor if all the victims sued him for damages.

Transfusion Dangers.

IN last week's issue of THE MEDICAL PRESS AND CIRCULAR, page 118, we commented upon the fact that common salt may, under certain circumstances, act as a poison within the body. The use of normal saline solution for purposes of transfusion, whether intravenous or subcutaneous, has become so general that hardly any doubt has been raised, hitherto, as to its beneficent influence in cases of shock or collapse. The question appears to be not merely whether such and such a fluid possesses any deleterious effects upon the red blood-corpuscles, but rather if it be isotonic or otherwise with the blood-plasma. Dr. A. P. Beddard, in a clinical lecture recently delivered at Guy's Hospital, reviews the whole subject of transfusion, together with the various methods employed and the dangers that may be encountered in its performance. Theoretically, it is stated that a 5.8 per cent. solution of pure dextrose is perfectly isotonic with blood-plasma. This substance is best introduced into a vein, especially in conditions of uræmia and loss of fluid from the vascular system. The majority of sodium and potassium salts have more or less poisonous properties, and ordinary salt solution, as commonly employed for transfusion, is more toxic than a solution of dextrose, particularly in those toxæmias in which the patient has not lost a large quantity of salts from the vascular system. One case is narrated in which sodium bicarbonate was used intravenously for diabetic coma, the object of the alkali being to neutralise the effect of the acid intoxication met with in this condition. Severe pyrexia ensued, the temperature reaching 109.5° within half an hour of death. The danger of sepsis from continuous transfusion, especially in diabetics, is pointed out, as well as the risk of over-

distending the right heart from an intravenous injection given too quickly. The subcutaneous route appears to be the best in most cases in which this method of treatment is called for.

The Changes in the Final Examination of the Royal University of Ireland.

THE changes which we recorded last week as having been made in the examination for the medical degrees of the Royal University of Ireland will, we believe, be welcomed by both students and examiners. The examination in the past has on the whole been an excellent one, but it has been unduly extended, and we have heard many complaints of candidates having reached such a stage of mental and physical exhaustion by the time the last day was reached as to be quite unable to do justice to their knowledge. An attempt was made to correct this fault at the spring examinations of the present year, and students were for the first time allowed to decide beforehand whether they would present themselves for a "pass" or for an "honour" examination. This arrangement seemed at first to offer an advantage over its predecessor, but when put to the test of practice it completely broke down, and was censured alike by student and examiner. By the new arrangements, the pass examination will be held exactly as heretofore, but two important changes have been introduced into the honour examination. In the first place candidates will be allowed to specialise in honours, and to present themselves in one or more of three groups:—Medicine and allied subjects, surgery and allied subjects, midwifery and gynaecology. In the second place, the honour examination will be entirely a written examination. In assessing the honours, the entire marks obtained by the candidate at the pass examination in the particular groups he has selected, together with the marks obtained at the honour examination, will be taken into account. Exhibitions will be awarded, having regard to all the marks obtained at both the Pass and Honour Examinations. The scheme on the whole very closely corresponds with what has been known to be the opinion of the examining board for some time, and we believe it will be well received by examiners.

PERSONAL.

THE presidency of the Medico-Legal Society has been accepted by Sir Joseph Walton, one of His Majesty's Justices of the Supreme Court in succession to Sir William J. Collins, the first President.

SURGEON-GENERAL SIR BENJAMIN FRANKLIN, K.C.I.E., late Director-General, Indian Medical Service, has been appointed a Knight of Grace of the Order of St. John of Jerusalem in England.

DR. CHALMERS WATSON, Edinburgh, has been awarded the Alvarenga Prize of the College of Physician of Philadelphia, for an essay on "The Importance of Diet: an Experimental Study from a New Standpoint."

MRS. THOMAS WHARRIE has given a generous dona-

tion of £5,000 to St. Mary's Hospital, and the late Miss Agnes Abercrombie £1,000 to the Edinburgh Royal Infirmary.

DR. ALFRED EDDOWES, of London, has been elected a corresponding member of the Société Française de Dermatologie.

DR. JOHN E. JONES, of Washington, has been appointed by President Roosevelt to be United States Consul at Dalny, in Manchuria, which is now in the hands of the Japanese.

DR. JAMIESON, the South African Premier, arrived last Saturday at Southampton. He is reported to be suffering from an attack of carbuncle, which make it necessary for him to cancel all engagements before proceeding to Carlsbad.

THE late Sir John Willox, editor and proprietor of the *Liverpool Courier* has bequeathed to the Royal Infirmary, the Southern Hospital, and the Stanley Hospital, Liverpool, each £10,000. £10,000 is also bequeathed to the sanatorium in Delamere Forest, to be invested to form what is to be known as the "Lady Willox Endowment Fund."

CAPT. N. J. C. RUTHERFORD, Royal Army Medical Corps, from Capetown, has been appointed to the London district from September 1st.

THE President of the Royal College of Physicians, London, announced that the Bradshaw Lecture on Exophthalmic Goitre and its Treatment, would be delivered by Dr. G. R. Murray, on November 7th; and the FitzPatrick Lectures by Dr. Norman Moore on November 9th and 14th. The subject of the first lecture would be, John Mirfield (1393) and Medical Study in London during the Middle Ages.

Special Correspondence.

[FROM OUR OWN CORRESPONDENTS.]
SCOTLAND.

THE CHAIR OF MIDWIFERY IN EDINBURGH UNIVERSITY.—The University Court has decided to institute a lectureship in gynaecology, and to proceed to the appointment of a Professor of Midwifery. The duties of the Professor and Lecturer will be adjusted by the University Authorities, on consultation, we presume, with the managers of the Infirmary and Maternity Hospital, for it is to be supposed that the new Professor will, like his predecessors, have a post on the staff of the latter institution and that the University ward for the Diseases of Women will be placed under the charge of the new Lecturer. Applications for the posts with testimonials, must be in the hands of the Secretary to the Curators of Patronage, Mr. R. Herbert Johnstone, W.S., 4, Albyn Place, Edinburgh, on or before Friday, September 15th next.

GRADUATION CEREMONY, EDINBURGH UNIVERSITY.—Unusual interest attached to the summer graduation of 1905, which was held on July 28th, because it was the occasion of Professor Simpson's farewell to the University in which he has laboured so long. The promoter entitled his address "Religio Obstetrici," and, after alluding to his resignation, Professor Simpson went on to speak of the changes which had taken place, of the progress that had been made, since his student and apprentice days. When he began to lecture there was one German obstetric journal, none in French; now he saw six German and six French, besides Italian, Roumanian, Russian and Japanese. When he began to study the system of apprenticeship had not quite died out, and it was his good fortune to be apprenticed to John Goodsir; since then the examination system had grown up till it had become a multiplied misery. The archaic examinations of the speaker's early days were then referred to—how he got his degree with two written examinations of two days each, and an oral

examination of the simplest. Again, in Professor Simpson's studentdom an interchange of Professors among the various chairs took place to an extent impossible now. Sir Douglas Maclagan taught *materia medica*, then Medical Jurisprudence, and was also a clinical teacher. When Alison resigned the chair of medicine Sir James Young Simpson was urged to become a candidate. When Laycock got the chair of Medicine against Wood, the latter threatened to teach midwifery in opposition to Simpson, while Traill was reputed to be able to take the place of any colleague who was ill—only drawing the line at the class of clinical surgery. Of the factors in the advance of science during his lifetime the two chief were the extended range of observation opened by the spectrum and electricity, and the guidance given to imagination by the doctrine of evolution. In seven paragraphs the speaker tried to reproduce the transformations of thought he had been made to see:—1. Ether, conceived as a fluid, the fundamental of matter, which displays itself under the influence of force or energy. 2. The earth has grown old—the 6,000 years of its boyhood had changed to thousands of ages. 3. He used to be taught that in six days it had got its final and fixed form; now it was still in the making. 4. The elements are dissolved, and now we seemed to have come to the borderland where ether clothed itself with matter, when the mutation of one element into another may take place. 5. The unit of biology has been transformed from the cell to the chromosome and nuclear elements. 6. Life is continuous. 7. The germ plasm eternal. The address concluded with the following eloquent peroration. "It may chance that some July day far down the century, when I have long been in the ether, one or other of you will talk with child or grandchild of the years when the century was young. Among its unforgotten scenes there will rise before your mind the memory of the day when at last you burst the chrysalis shell of pupillage to lift free ways into the azure. You will recall the unusual concurrence of the simultaneous leave-taking of the University by the graduates and their promoter. 'We came away,' you will say, 'a goodly company, together, through the gateway that leads to the rosy dawn. He passed out, all alone, through the door that looks to the sunset and evening star. He was an old man like me,' I forehear you say. 'Not in himself a great man, he had been the friend of great men, and came out of a great time in the 19th century, "when there was midsea and the mighty things," and it looked to the men of his generation as if old things had all passed away and a new world begun. And he told us that the great lesson he had learned through life was the same that the disciple who leaned on Jesus' breast at supper taught to the fathers, the young men, and the little children of his time, when he said: 'The world passeth away, and the lust thereof; but he that doeth the Will of God abideth for ever.'" Farewell."

When Professor Simpson had concluded, Mr. Norman, President of the Students' Representative Council, presented an address to the retiring Professor, and the Vice-Chancellor paid a tribute on behalf of the Senatus. The proceedings were concluded by the benediction pronounced by Prof. Taylor.

BELFAST.

DOWN DISTRICT ASYLUM.—The annual report of this institution has just been published by Dr. Nolan, the resident medical superintendent. The admissions during the year were 179, 99 males and 80 females, and the discharges were 84, 36 males and 48 females, while 58 patients died. The daily average number of cases under treatment was 67.3, comprising 370 males and 303 females, and the average cost of maintenance of each patient for the year, calculated on the gross expenditure, less repayment of loans, was £24 4s. 7d., as against £25 4s. 2d. for the previous year. Deducting receipts from paying patients, capitation grant, &c., the actual cost of maintenance on the local rates stands at £7 15s. 8d.

THE WATER SUPPLY IN ULSTER.—The heavy fall of rain last week was very welcome in Ulster, as in a number of the small towns the water supply was almost exhausted. In Larne and Holywood the condition of affairs threatened to become very serious, and much inconvenience was experienced. In the latter town a medical practitioner called out to an emergency operation at night could obtain no water to boil his instruments in!

HEALTH OF BELFAST.—During the four weeks last reported there were 158 cases of zymotic disease notified in Belfast, and 62 deaths were registered from the same causes. Typhoid has diminished, there being 32 cases, and only one small-pox case occurred. There is an epidemic of measles at present, and 17 deaths occurred from it, while 26 deaths were attributed to diarrhoea. There were 104 deaths in children under one year old, equal to a rate of 3·7, while the total death-rate was 17·1.

OPENING OF A NEW OPERATING THEATRE IN CORK.

ON July 20th, in the presence of a large gathering of friends and supporters of the Hospital, a new operating theatre was opened at the North Charitable Infirmary. The new block consists of the theatre proper, an anæsthetic room, a sterilising room, and a preparation room. The theatre contains the most recent improvements, and is heated on the Plenum system. Professor Pearson, in the course of a short statement as to the origin, nature and arrangement of the building stated, that in response to an appeal from him, the theatre had been presented to the Infirmary by Miss Belle Honan. On the proposal of Mr. Harding, J.P., a vote of "sincere and grateful thanks to Miss Honan for her munificent gift" was adopted with acclamation, and shortly afterwards the proceedings terminated.

Obituary.

THOMAS BOLES EAMES, M.R.C.S.ENG.,
L.R.C.P.ED.

THE death of Dr. Thomas Boles Eames, of Welford-on-Avon, formerly a well-known practitioner in the neighbourhood of Farnworth and Kearsley, will be greatly regretted by those who once enjoyed his services as doctor and friend. He completed his eighty-third year in January last, and received his education at Cork, afterwards studying medicine in Dublin. He became a member of the Royal College of Surgeons of England in 1845, and in 1859 he obtained the Licence of the Royal College of Physicians of Edinburgh. Besides having a practice covering a district extending as far as Ainsworth, Little Hulton, and Clifton, he was club doctor at the old Prestolee Cotton Mill. He was President of the Bolton Medical Society about 1878, and was one of the founders of the Manchester Medico-Ethical Association.

Correspondence.

DR. WALSH'S METHOD OF SCALP-ISOLATION OF RINGWORM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.
SIR,—With regard to Mr. Pearse's annotation in your last issue as to the use of the biniodide of mercury in ringworm. I can endorse its value in some cases. But, like all other remedies claimed as specifics, its failures far outnumber its successes. That point was carefully emphasised by Dr. Walsh in his important communication. His aim was to advocate not any particular method of cure but rather to describe a practical method of prevention. What is that plan? It is, briefly, to substitute local for general isolation; to isolate the affected scalps where it would be

impossible to isolate the children bodily. By a happy chance it comes about that the systematic removal of the adherent cap-film shortens the period of treatment. The essential triumph of Dr. Walsh's procedure is that it enables children affected with ringworm to attend school with impunity. Of course, there is nothing new in the application of medicated collodion, but the masterly idea of general adoption of scalp isolation is original, and, to my mind, final. The London County Council can hardly consider the future of school ringworm apart from the suggestion to start central institutions for the systematic treatment of public education scholars by scalp isolation.

I am, Sir, yours truly,

A SENIOR DERMATOLOGIST.

London, August. 3, 1905.

Literature.

MERCK'S ANNUAL REPORT FOR 1904.

THE excellent annual report on the therapeutic advances of each twelve months published by Messrs. Merck and Company, now occupies an established position in medical literature. Although issued by a manufacturing firm it maintains throughout a spirit of absolute impartiality. The work is extensively used as a book of reference, but is hardly as widely known as it deserves to be amongst medical men who are interested in scientific pharmacy and therapeutics. The field of knowledge opened out in this way by modern research appears to be well-nigh illimitable. Much of the literature that is published on the subject hails from interested quarters, while a good deal more must be regarded as simply of a hasty, tentative, and fleeting origin. Under such circumstances it is of importance to be furnished with a trustworthy key in which scientific accuracy and simple directness of statement are the essential features. Personally, we have found Merck's little volume a handy and convenient book of reference.

Pass Lists.

Army Medical Service.

THE undermentioned candidates were successful at the recent competitive examination in London for Commissions in the Royal Army Medical Corps, and for which sixty candidates entered. Names are arranged in the order of merit:—John Allan Anderson, M.B., Ch.B.Ed., Cuthbert G. Browne, M.R.C.S.Eng., Hugh Godwin Sherren, M.R.C.S.Eng., Henry Horace Andrews Emerson, M.B., B.Ch.Dub., Wallace Benson, M.B., B.Ch.Dub., Rowland Philip Lewis, M.R.C.S.Eng., George Edward Ferguson, M.R.C.S.Eng., James Herries Graham, M.B., B.S.Dur., Charles Ernest White Spinner Fawcett, M.B., B.Ch.Dub., Thomas Scatchard, L.S.A.Lond., Ronald Anderson Bryden, M.R.C.S.Eng., Arthur Edmund Stewart Irvine, L.R.C.P.&S.I., Thomas Bettesworth Moriarty, L.R.C.P.&S.I., Alexander Macgregor Rose, M.B., B.S.Aberd., Edward Lawton Moss, M.R.C.S.Eng., Edward Guy Anthonisz, M.R.C.S.Eng., Griffith Henry Rees, M.B., B.S.Lond., M.R.C.S.Eng., Vivian Hood Symons, M.R.C.S.Eng., Walter John Weston, M.R.C.S.Eng., Mortimer John Cromie, M.R.C.S.Eng., Percy Farrant, M.R.C.S.Eng., Albert Edward Francis Hastings, L.R.C.P.&S.I., George William Webb Ware, M.B., B.Ch., R.U.I., Michael Balfour Hutchinson Ritchie, M.B., B.S.Aberd., James Stuart Dunne, F.R.C.S.I., William McConaghy, M.B., B.Ch.Ed., Francis Cornelius Sampson, M.B., B.Ch., R.U.I., Charles Francis White, M.B., B.Ch., R.U.I., Cecil John Wyatt, M.B., B.Ch.,Dub., Wilfrid Cowan Nimmo, M.R.C.S.Eng., Edmund Thurlow Potts, M.D., Ch.B.Ed., Michael Keane, L.R.C.P.&S.I., Arthur Drought O'Carroll, M.B., B.Ch.R.U.I., Robertson Stewart Smyth, M.D., B.Ch.Dub., Arthur James Arch, M.R.C.S.Eng., Thomas Somers Blackwell, L.R.C.P.&S.I., Harold Edgar Priestley, M.R.C.S.Eng., Alan Cuncliffe Vidal, L.R.C.P.&S.Ed., Philip Jauvriin Marett, M.R.C.S.Eng., Hugh Stewart, M.B., B.Ch.

Notices to Correspondents, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

CLUB DOCTOR (Blantyre).—There are no new developments in the relations existing between friendly societies and medical men in Coventry, save that it is an almost foregone conclusion that the 4s. 4d. instead of 3s. asked per member will probably be refused. Some of the doctors are of opinion that children should pay more than adults, as they require three times as much attendance.

DR. H. (Sydenham).—Under the new regulations of the L.C.C. Board of Education vaccination is not compulsory for pupil teachers until they come under the Board of Education. The pamphlet issued by this Board on Education in Hygiene and Temperance, issued by the L.C.C., can be had at the Embankment offices of the London School Board.

M. L.—The use of the tetanus antitoxin has not proved successful in all cases. But the value of it is shown by the fact that mortality in the disease is reduced from 90 to 59 per cent.

AN ANTIENT REMEDY.

She bore hym in her arms, and hurried to a Rheum, where he mite be quiet, gave hym bred and meet, held a cent bottel under hes knows, untile neckerchef, rapped hym up warm and gave hym a sulte drachm. —*St. Nicholas.*

DR. H. R. S.—You will find the monthly proceedings of the Midwives' Board duly reported in our columns. The last report appeared in our issue for August 2nd.

MR. R. S. MOSS is thanked for his communication, which he will see has been utilised.

D. P. H.—The sanitation of restaurant kitchens is a question which cannot be brought up too often. We agree with you that an authoritative inspection would secure a plentiful crop of unpleasant revelations.

PRACTITIONER.—Personalities of a virulent type under a pseudonym would hardly be accepted in this journal. We therefore return your letter sent for publication.

MR. H. MURDOCK.—The subject is under investigation. Report will be made in due course.

FIFTH YEAR.—We understand that a new edition is in the Press of the book referred to.

Vacancies.

- Royal Surrey County Hospital, Guildford.—House Surgeon. Salary £100 per annum, with board, residence, and laundry.—Applications to the Hon. Secretary at the Hospital.
- Royal Surrey County Hospital, Guildford.—Assistant House Surgeon. Salary £50 per annum, with board, residence, and laundry. Applications to the Hon. Secretary at the Hospital, on or before Monday, August 14th, 1905.
- Royal College of Surgeons in Ireland.—Senior Demonstrator in Anatomy. Salary £100 per annum. Applications to G. F. Blake, Registrar.
- Royal National Sanatorium, Bournemouth.—Resident Medical Officer. Salary £10 per month, with board, residence, and washing. Applications to the Secretary.
- Bury Infirmary.—Senior House Surgeon. Salary £110 per annum, with board, residence, and attendance. Applications to Honorary Secretary, Dispensary, Knowsley Street, Bury, Lancashire.
- Exeter City Asylum.—Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Applications to the Medical Superintendent, Digby, Exeter.
- Roxburgh District Asylum, Melrose, N.B.—Assistant Medical Officer. Salary £140 per annum, with board, rooms, &c. Applications to Medical Superintendent.
- Royal South Hants and Southampton Hospital.—House Physician. Salary £100 per annum, with rooms, board, and washing. Applications to T. A. Fisher-Hall, Secretary.
- Royal Victoria Hospital, Bournemouth.—A House Surgeon. Salary £100 per annum, with board and lodging. Applications to the Secretary.
- Noble's Isle of Man Hospital and Dispensary, Douglas, Isle of Man.—Resident House Surgeon. Salary £90 a year, with board and washing. Applications to Richard D. Gelling, Honorary Secretary, St. George's Chambers, Athol Street, Douglas, Isle of Man.
- The Municipality of the Town of Singapore, Straits Settlements.—Assistant Health Officer. Salary £400 per annum. Applications to C. C. Lindsay, Esq., M.Inst.C.E., 180, Hope Street, Glasgow.

Appointments.

CLAY, ROBERT HOGARTH, M.D., M.R.C.P., Edin., Hon. Medical Adviser to the Devon and Cornwall Home for Consumption, Didsworthy.

COLLIER, H. W., M.B., B.S., Clinical Assistant to the Chelsea Hospital for Women.

CORBETT, W. E. MANDERSON, L.R.C.P. and S. Irel., Honorary Medical Adviser to the Devon and Cornwall Home for Consumption, Didsworthy.

JACKSON, GEORGE, F.R.C.S. Eng., L.R.C.P. Lond., Hon. Medical Adviser to the Devon and Cornwall Home for Consumption, Didsworthy.

LINDSEY, COLIN DUNROD, M.A., M.D., B.C., D.P.H. Cantab., Hon. Medical Adviser to the Devon and Cornwall Home for Consumption, Didsworthy.

MAURICE, W. B., M.R.C.S., L.R.C.P., Clinical Assistant to the Chelsea Hospital for Women.

ROBINSON, W. L.R.C.P., L.R.C.S., Clinical Assistant to the Chelsea Hospital for Women.

TAYLOR, MARK RONALD, L.R.C.P. Lond., M.R.C.S., Medical Officer of Health of Helston, Cornwall.

TOYE, EDWIN JOSIAH, M.D., B.S. Lond., F.R.C.S. Eng., L.R.C.P. Lond., Medical Officer of Health for the Northam (Devon) Urban District Council.

WEBBER, H. WOOLMINGTON, M.D., M.S. Lond., F.R.C.S. Edin., Hon. Medical Adviser to the Devon and Cornwall Home for Consumption, Didsworthy.

WOOLLCOMBE, WALTER LEY, F.R.C.S. Edin., M.R.C.S., L.R.C.P. Lond., Hon. Medical Adviser to the Devon and Cornwall Home for Consumption, Didsworthy.

WRIGHT, EDWARD ARTHUR, M.B., M.S. Edin., Hon. Consulting Surgeon to the Huddersfield Infirmary.

To the Richmond, Whitworth, and Hardwicke Hospitals the following appointments have been made:—House Surgeon, Dr. H. R. C. Rutherford; House Physician, Dr. J. W. Houston.

Births.

LEGGE.—On August 6th, at 18, Cheyne Row, Chelsea, the wife of Thomas M. Legge, M.D., of a son.

POLLARD.—On August 4th, at the Royal Naval Hospital, Chatham, the wife of Inspector-General E. R. H. Pollard, R.N., of a daughter.

Marriages.

BRUCE—HELM.—On August 3rd, at St. Mary the Virgin, Penzance, the Rev. J. Collingwood Bruce, son of the Right Hon. Sir Gainsford and Lady Bruce, to Bertha Helm, daughter of the late George F. Helm, of Marazion, Cornwall.

SCOTT—WILSON.—On August 3rd, at St. Bernard's Church, Edinburgh, Wm. Thurburn Scott, M.B., second son of Russell Scott, Shoreham, Kent, to Frances Wilson, youngest daughter of John Wilson, Castle Park, Huntly, N.B.

Deaths.

BECK.—On August 3rd, at the North-Western Hotel, Dublin, Eleanor Eliza (Nellie), of Queenstown, formerly of Kingstown, second daughter of the late Surgeon Herbert Browne Beck, of Bermuda and Alderney.

OPERATIONS—METROPOLITAN HOSPITALS.

- WEDNESDAY.**—St. Bartholomew's (1.30 p.m.), University College (2 p.m.), Royal Free (2 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. Thomas's (2 p.m.), London (2 p.m.), King's College (2 p.m.), St. George's (Ophthalmic, 1 p.m.), St. Mary's (2 p.m.), National Orthopaedic (10 a.m.), St. Peter's (2 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), St. Ormond Street (9.30 a.m.), St. Northern Central (2.30 p.m.), Westminster (2 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), Cancer (2 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).

Original Communications.

THE HIGH INFANTILE MORTALITY RATE,

THE FAR HIGHER INFANTILE DETERIORATION RATE, AND THE MEANS TO CHECK THEM. (a)

By GEORGE CARPENTER, M.D.LOND.,

Editor and Founder of the *British Journal of Children's Diseases*; Physician to the North-Eastern Hospital for Children; Medical Officer of Health for Beckenham; formerly Physician to the Evelina Hospital for Sick Children.

THE Registrar-General's returns for 1904 show that the average death-rate for the seventy-six great towns of England and Wales was 17·2 per 1,000, while the infantile mortality rate of children in the first year of life was 160 per 1,000 births. In 142 other towns it was 154 per 1,000, and for rural England and Wales 125 per 1,000. Certain other large towns showed a still larger rate; thus, Birmingham was 197; Liverpool, 196; Stockport, 203; Hanley, 212; Preston, 218; and Burnley, 229. In London the highest borough rate was that of Bermondsey, which was 172, and the lowest was Marylebone, with a total of 94.

The infantile mortality rate in the various wards of Birmingham has been shown to be no less than 331 for St. Mary's, and 263 for St. Bartholomew's, the least being 133 for Edgbaston and Harborne; and there is reason to believe that selected districts in other large towns would show equally startling figures.

Of provincial towns Bournemouth was 111; Hastings, 108; King's Norton, 100; and of London suburbs Willesden, 114; Beckenham with the low general death-rate of 91 was no less than 126.

There can be no question from a study of these startling national statistics that the infantile death-rate is excessive, and a standing menace to the country. Further, this waste of infant life is a class mortality—it is practically confined to artisans and the labouring classes, and does not exist to any serious extent in the upper and middle classes. Although in the upper and middle classes infantile lives are not in such jeopardy, the infants born to these classes are very prone to diet disorders and suffer thereby through life from the lack of vigour—physical wrecks in sequence to readily preventable conditions. During the past decade the birth-rate in the United Kingdom has steadily diminished. Had it not been for the alien immigrant the actual population of England would have decreased.

The infantile mortality question is one, therefore, of extreme importance, not only in relation to the growth of the population, but in regard to the physique of the nation. While thousands perish outright, hundreds of thousands who worry through are injured in the hard struggle for existence and grow up weak-

lings—physical and mental degenerates. A high infantile mortality rate therefore denotes a far higher infantile deterioration rate, and this unwelcome fact must not be lost sight of.

Of all the causes, and they are numerous, which lead to this large sacrifice of infant life, and to the undermining of the infant physique, food is the most important. Improper feeding is mainly responsible for infantile deaths and disease. Three-fourths of the deaths of children under 12 months of age occur among those who are bottle-fed. This enormous mortality and widespread production of disease can be largely prevented by breast-feeding, and failing maternal nursing, by the use of pure cow's milk in suitable dilution. Of the two methods, the former, or Nature's method, is the only one that can be recommended. The latter is to be viewed merely in the light of a makeshift. The large majority (75 per cent.) of mothers are capable of nursing their children, though in the upper classes the percentage that perform their maternal duties in this respect is very small indeed.

Von Bunge, of Bâle, asserts that a deficiency in maternal milk is due to the imbibing of alcohol by the parents. His statistics, drawn from all Europe, show that women with an insufficient supply of milk are usually the daughters of alcoholics. He asserts that if two generations have been alcoholic the women of the third generation will almost certainly be unable to nurse their children. The importance therefore of alcoholic temperance in indirect relation to infantile mortality is obvious.

A number of poor women, by reason of their having to find employment in mills, factories, warehouses, and elsewhere, are unable to nurse their children, and certain others fail in this respect owing to ill-health and lack of sufficient nourishment. The Factory Act provides that a woman shall not be employed within four weeks of child-birth. To ensure the carrying out of this Act, *ten* ladies are employed throughout the United Kingdom. Comment is not necessary. It would be a source of great protection to infant life and health if suckling mothers were not allowed to leave their infants to follow their employments. Women who can nurse should be encouraged to do so, for therein lies the secret of a healthy and peaceful infancy and a vigorous childhood and manhood. Steps should be taken to impress upon mothers the importance of performing these maternal duties for the sake of their own health as well as for that of their offspring. They must be taught that breast milk is the proper food for the child, and that there is no substitute for breast milk. The term “humanised milk” should be abolished; mothers are misled thereby, and are apt to assume that “humanised milk” is just the same and just as good as breast milk, and that it can be used in the same way.

To popularise maternal nursing among the poor, it would be well to institute local charitable societies for the award of prizes to the most successful mothers and for the payment of gratuities, or for the provision of nourishment where necessary, to enable mothers

(a) An Address delivered at the London Congress, Royal Institute of Public Health, Section Child Study and School Hygiene, July, 1905.

to properly carry out their duties. The societies would also, through their medical officers, look after the health of mothers during lactation, and would instruct those about to become mothers as to the best way to preserve their health during pregnancy and to bring forth healthy offspring at term.

Where breast-feeding is impossible or can only be partially undertaken the rearing of the infant by artificial methods becomes necessary, but not until then. For this purpose cow's milk is the substitute.

The bottle-fed infant requires *pure* uncooked cow's milk, suitably diluted according to its age, and it should be the aim of municipalities to provide nurslings and others with a commodity which is above suspicion, and not with a product so filthy that sterilisation becomes imperative. (a) Certain municipalities, following the lead of the Societies of the Gouttes de Lait of France—towit, Liverpool, Battersea, Leith, St. Helen's, Glasgow and others—recognising their duties towards the infant population, have endeavoured to reduce the infant mortality rate by supplying sterilised milk at milk depots. While one cannot but applaud their noble efforts in aid of suffering infantile humanity, one cannot but feel that their methods are faulty. From the financial side they have not as yet proved remunerative, as they are not very popular. So far they appear on paper to have been fairly successful in their aim—the reduction of infant mortality. Thus, the mortality rate of the depot-fed infant appears to be decidedly less than that of the general infantile mortality rate of the towns in which the depots are situated. The numbers are, however, too small to draw any reliable deductions therefrom, and there are other fallacies.

There are two great objections to milk sterilised at the depot. One of them is that boiling milk does not destroy the poisonous products which the bacteria have produced in transit, though cooking is inimical to the microbes. The other objection is that milk so treated is apt to produce scurvy, anæmia, and malnutrition in the nursling. In the May, 1904, issue of the *British Journal of Children's Diseases*, in an editorial under the heading of "Municipal Milk Supplies," it was pointed out that sterilising, humanising, &c., are means employed by medical men for special reasons and for a limited period; but they produce such changes in the milk that their employment on a large scale and apart from medical advice is not justifiable. Further it was stated: "We have the greatest respect for the medical officers of health in this country when carrying out their own work, but the feeding of infants is rather outside their sphere and is a branch of medicine in which few of them have had any special training or experience. Their statistical results as to feeding by municipal milk form most interesting reading, but we are not prepared to accept them as finally settling problems which have exercised and are still exercising all the skill of specialists in diseases of children. The effects of a dietary on a large number of infants can only be correctly estimated by those who have had the children directly under their own observation. Statistics as to the death-rates of infants fed on municipal milk, and others not so fed, are practically worthless, because so many unknown factors come in."

Municipalities have a great work before them, viz., the stiffening of the present regulations under which milk is produced, carried by cart and rail, and stored and delivered to the customer. The speedy formation of some central authority—a special Government Department—is required to formulate stringent regulations and to efficiently control the milk trade of the country. From the time the milk leaves the ill-kept cows and its passage over the manure-begrimed hands of the milker until its arrival at the customer's dwelling it receives but scant attention saving that of the unscrupulous dealer, who, by various injurious chemical adulterations—boric acid and

other deleterious drugs—retards decomposition for a time.

Regulations are required to compel—

(1) The grooming of milch cows, the keeping of their bodies sweet and clean, and ablutions of their teats and udders before milking.

(2) The suitable feeding of milch cows.

(3) The proper stabling and bedding of milch cows.

(4) Cleanliness of cow tenders and milkers and the suitable clothing of the latter when milking.

(5) The aseptic conduct of milking operations.

(6) Suitable treatment of the milk during and immediately after milking.

(7) The subsequent transference of the milk to suitable glass or other stoppered receptacles, and the appropriate treatment of these receptacles when not in use. Investigations recently undertaken by Dr. G. H. Steward, of the Philadelphia Bureau of Health, show that specially prepared paper bottles can be used with advantage for this purpose. Bacteriological tests showed that the milk in the paper bottles contained fewer bacteria than that in the glass receptacles—on an average about one-fourth—and the milk kept sweet two days longer. The cost of the bottles is trifling and the price of the milk is not increased by their use, and when emptied they can be thrown away.

(8) The better and more rapid transit of bottles of milk to and by rail in refrigerator vans and the speedy abolition of the milk-churn.

(9) The storage of milk in stoppered bottles on ice or in specially chilled receptacles in the milk-shops.

(10) The delivery of chilled milk to the customers in stoppered bottles by special refrigerator carts.

(11) The municipalities, in addition to the ordinary methods of chemical analysis, should undertake frequent bacteriological examinations. The number of microbes per cubic centimetre should be estimated, and also the percentage of lactic acid in the milk, so as to control not only obvious additions and subtractions, but also the methods of collection as regards cleanliness.

(12) Increased powers are required to enable milch cows to be tested by tuberculin.

(13) The dispensing at the farm, under municipal control, of uncooked milk in simple dilutions of appropriate strength for infant feeding, according to age, to be placed in stoppered bottles, each bottle to contain sufficient for one feed, and a suitable number of bottles to be supplied for a day's consumption, and packed in appropriate wicker baskets or other receptacles. Printed instructions, in simple language, in regard to infant feeding should accompany the baskets.

(14) To prevent the abuse of the municipal milk depot and the encouragement of bottle-feeding the milk should be supplied to the customer only on a doctor's order.

It is important that provision should be made for the municipal-milk-fed infant to be reared *under medical guidance*, and that the progress made by the infant should be registered weekly, so that its feeding can be scientifically controlled and modified whenever necessary, and its health be supervised. Municipalities should not seek to make themselves responsible for infant feeding, in regard to which they possess no qualification, but rather should they devote their attention to the provision of a *pure* commodity—a necessity for young and old alike.

To obviate the milk depot being turned into an out-patient department, arrangements might be advantageously made with the children's hospitals or other hospitals to undertake the work of the depot for the localities in which they are situated. This plan would insure skilled medical attendance by recognised children's specialists and would help to popularise the movement. The sanitary and financial control would remain in the hands of the public health authorities as at present and the medical arrangements would be supervised by those who are best able to advise on such matters. Such a system would prevent

(a) *Vide* Editorial: "The Milk supplied to Infants," *British Journal of Children's Diseases*, February, 1904; also Editorial: "Milk Dispensaries for Children's Hospitals," *ibid.*, March, 1904.

friction with hospital authorities and local practitioners, and would prove a very powerful combination for good. This plan would give the children's hospitals an opportunity of obtaining that for which there is so great a need at present—a *pure*, wholesome, uncooked food.

The present system of administering out-patient relief at the children's hospitals and at other hospitals where infantile disorders are treated is unsatisfactory.

The infantile mortality rate of those attending these departments is large, and this is the case because it is most difficult, for a variety of reasons, to carry out a treatment on these patients.

The majority of the infants are brought for dietetic disorders. The physician readily detects the nature of the ailment and suitably prescribes, but the power to assist mostly ends there. If the illness be due to dietetic errors, the mother is given a paper of instructions along with a prescription. The directions for feeding are good, but the giving of the paper to the mother is not sufficient for the end in view. The bottle of medicine is considered the most important outcome of the hospital visit; it is tasted and sampled with approval or the reverse by the mother and her acquaintances, but the printed instructions are crumpled up and often mislaid before the hospital precincts have been left. In these cases, to be able to prescribe a suitable clean milk mixture would be a great boon to the doctor as well as to the infant.

A year or so ago I advocated the creation of Milk Dispensaries (a) for the dispensing of pure milk and pure diluted milk in connection with the children's hospitals, particularly in connection with the North-Eastern Hospital for Children, Hackney Road. The House Committee of the Hospital and their chairman (Mr. C. J. Port) favourably viewed the idea. The difficulty of obtaining a *pure* milk was quickly discovered when the matter was gone into and the leading dairies were visited; and there was some hope when this state of affairs was recognised that the Hospital, either alone or in combination with other similar institutions, would be able to manage a dairy-farm on the most approved modern principles for the supply of milk. Lack of funds for the purpose and important building works on hand prevented the fruition of the scheme, and the infantile out-patients are still in want of a prime necessity for their successful treatment, viz., *pure milk*. It was proposed that milk should be paid for by those patients who could afford to purchase it, and that it should in deserving cases on inquiry by the almoner be supplied below cost price.

In connection with the children's hospitals there should also be some system whereby the treatment of out-patient infants could be carried on at their homes. Such a plan would preserve many infantile lives to the nation, and improve the national physique. An efficient visiting nursing staff for local cases is a necessary part of a children's hospital equipment. The nurses' duties would be to superintend the carrying out of the physician's directions, and to give practical instruction in simple hygiene and the domestic duties incumbent on women and mothers. These nurses should be required to have been thoroughly trained in a children's hospital, and to be well grounded in all domestic duties.

They could either be in the hospital employ, or their services—if in the future a municipal milk depot is to be a part of a children's hospital equipment—might be obtained on application to the municipal authority in whose pay they would then be. For the creation of a thoroughly efficient service such nurses ought to be under the immediate control of a hospital-trained matron, and act under the direction of the medical staff. This latter I look upon as most important. To encourage the creation of a number of special district nurses, lady sanitary inspectors, lady health visitors, call them what you like—and I have in mind Huddersfield and other provincial towns and metropolitan municipalities where

such appointments have been made—responsible to none but themselves for the advice they give, will be but the making of a superior race of "Gamps" and in the end prove quite as objectionable. As long as these women confine their attentions to carrying out the doctor's orders, they will prove of great usefulness. Emancipated from the only real source of restraint, the doctor, the temptation to give medical advice will soon be yielded to, and with disastrous results to the community. Municipalities would exercise some restraint over these creations, inasmuch as they would be in their pay and subservient to their rules, but there would be no *real* restraining influence in such circumstances, and it is hoped that public health authorities will see to it that the public is properly safeguarded in respect to such appointments.

By such means as I have outlined appropriate nourishment can be brought within reach of the humblest nursing. But there are various difficulties other than the food question to contend against. One of these is to get in touch as quickly as possible with recently delivered women. It is important that the public health authorities should obtain early intimation of the births occurring in their districts. According to the present law births need not be registered for six weeks or more after the event, by which time many infants have succumbed. An alteration in the law is therefore greatly needed.

Huddersfield Council has endeavoured to solve the difficulty by offering a shilling reward to the first person who notifies the birth of a child to the Medical Officer of Health within forty-eight hours of the event. On receipt of the notification the parents are supplied with full instructions as to the feeding, washing, clothing, &c., of infants. Two lady visitors have been appointed to visit the homes of the women to reinforce the printed instructions by a personal interview. Glasgow has copied Huddersfield's methods.

For mothers who have to work away from home the provision of crèches, or day nurseries, under medical supervision, is a necessity. These were first established in France in 1844 by private enterprise; but now they have been taken over by the French municipalities, and children are fed and cared for there at a trifling daily charge, the mother having the right of admission at any time. Not only are these common in France, but they are to be found in the majority of continental cities. There are now some 55 crèches under medical supervision in London, managed by private bodies or individuals, but some of the largest and poorest districts in the Metropolis are unprovided for, or lack sufficient accommodation to meet the great demands made upon them. The need for crèches is now being realised by a few municipalities in London and the country, and powers will be sought in the near future by these corporations to legalise the formation of these very necessary institutions and to financially assist those already formed. The Acton Urban District Council recently applied to Parliament for power to maintain one or more crèches, but the application was refused on the ground that it was a novel proposition from a legislative point of view. A valuable suggestion has been made in regard to these institutions—that they should be made educational centres, and that girls over 14 years might be made to attend occasionally—and the teaching of infant management to such girls should be eligible for aid from the grant for public education.

For mothers who live at home domestic education is all-important. Women who have had no domestic training—who, reared in squalid homes, have spent their lives in factories and shops, who are unacquainted with simple health rules, who have had no experience of marketing, who are ignorant as to the proper storage of food, who are incapable of undertaking simple cooking, who are not thrifty, tidy, cleanly, and resourceful—cannot make good wives or mothers.

Good mothers are necessary for the reduction of infant mortality and for the production of a healthy

(a) "Milk Dispensaries for Children's Hospitals," *Brit. Journ. of Children's Diseases*, March, 1904.

race, and it is on the women that time and money must be spent to bring about the desired result.

How are the women to be approached? There are various channels, such as municipal lady health visitors, municipal classes of instruction, crèches, various religious bodies, the out-patient departments of hospitals, and workhouse nurseries. From a prolonged study of out-patient mothers, I consider that *practical demonstrations* are all-important. I have no faith in set lectures, which are wearying to the majority of educated people, but how unutterably boring to the superficially informed and to those of less acute intellect. The dissemination of knowledge by printed matter is productive of but slight good among the poorer classes. For some years in the annual reports of the Medical Officer of Health for the Urban District of Beckenham I have annually specially called attention to the excessive infantile mortality rate of the district and the plan to prevent it. Steps have been taken by the Press to diffuse this knowledge in the district, but the results have been barren and the high infantile mortality rate shows no abatement. A striking advertisement will readily attract them, but the exercise of a trifling mental effort to abstract information from even carefully prepared literature is rarely undertaken, and not to be expected. In education let us return to the three R's principles associated with a high standard of domestic instruction.

Elementary hygiene, domestic duties, marketing, cooking, thrift, orderly methods, needlework, the care, the feeding, the clothing and domestic hygiene of infants should be practically taught to every school-girl. A school was opened in January, 1904, at Harringay, for the instruction of girls between the ages of ten and thirteen in housekeeping, and there is a great need for similar educational establishments in other districts. Not only should girls be taught the domestic virtues in our public schools, but boys should be trained in all the essentials that produce good citizens and good fathers—respect for parents, cultivation of the natural affections, the love of home and country, duty to one's neighbour, personal cleanliness, obedience and decent behaviour, and the leading of well-regulated healthful lives.

Of social evils that make for untold misery in the home and pave the way for infant mortality, betting by the fathers and alcoholism in one or both parents take a prominent place. Carelessness and neglect on the part of the parents and infant guardians are deserving of punishment, and fatalities arising in sequence to these should receive greater attention by the coroners than at present.

Infantile life assurance should either be abolished or more strictly safeguarded; the present system is a premium on infant murder. A law has recently been passed in France which prohibits the insurance of children's lives under 12 years of age, an enactment which could be added with advantage to our statutes.^(a)

The workhouse nurseries which exist throughout the country and which annually administer to a multitude of infants and their mothers, offer exceptional facilities for the diffusion of knowledge in regard to infantile dietetics and management. From a leading article which appeared in the *British Journal of Children's Diseases*, entitled "The Care of Infants in Workhouses," June, 1904, it would appear that these unique facilities are ignored, and that the average medical officer cares little as to how the young children in the workhouse are fed, and is wholly apathetic as to the effect of his remissness on the national welfare. These nurseries are badly ventilated, cots for infants are condemned, overlying being encouraged thereby, and it would appear that the medical officers very rarely carry out the dietary order of 1900 of the Local Government Board, which includes a special proviso directing that the "medical officer" of the workhouse shall give directions in writing as to the service of food to the infants.

^{a)} "Child Life Insurance," *Brit. Journ. of Children's Diseases*, February, 1905.

The relationship of proprietary foods to infant mortality is not unimportant. At present these preparations are responsible for the loss of many infant lives and for much child suffering and deformity.

In a recent issue of the *Daily Mail* there was an advertisement issued by a West End firm of chemists—chemists to the King they state—headed "Fine healthy children: An article of the greatest possible interest to mothers, showing how to build up the body, brain, and muscle." The proprietors at great length point out that the future of the child largely depends on the food given during the first few months of life. They go on to state that their food is "the very best food you can give baby." Further, "a booklet will also be sent which is a guide to infant feeding." Their food, like many others, bulks largely in unaltered starch. This is not an isolated instance, and is taken haphazard from current literature; the advertisement columns of the public Press are full of such appeals to ignorant mothers. Needless to say the opinions of financially interested proprietary food vendors on the subject of what is the very best food you can give baby are not always in harmony with those of the experts—the children specialists—whose knowledge has been laboriously obtained by extensive clinical experience, and has been preceded by prolonged medical training.

Lying-in women, whose maternity is announced in the usual columns of the daily press, are speedily inundated with a variety of articles for the baby by philanthropic tradesmen with an eye to the main chance, the most prominent being proprietary food samples and their accompanying literature. Not content with appeals to an ignorant public by such means, these pushful proprietary food traders bombard the letter-boxes of the profession with pamphlets on infant feeding, and innumerable samples of their wares rattle into these receptacles with surprising regularity; and with unbounded impudence their brazen travellers seek personal interviews with the physician during his consulting hours to push their goods and *inter alia* teach him his profession! That such devices are considered to be worth the outlay incurred is a poor tribute to the knowledge and intelligent interest displayed by the bulk of the medical faculty on the all-important subject of infant feeding.

The advertisement columns of another paper, the *St. James's Gazette*, recently pointed out in large type "How infantile mortality may be controlled." The ingenious solution of the problem is provided by the answer "'Knowing the exact composition of Woodward's Gripe Water, I can with confidence recommend it.' A well-known London physician, name given privately." If I may offer a suggestion, a better solution than that would be knowing the source of the milk supply and its treatment, and the abolition of proprietary foods for young nurslings. There would certainly be fewer infantile stomach-aches. The specious advertisements of the vendors of proprietary foods—and without extensive advertising the commercial life of these preparations would be of short duration—attract the ignorant, and, failing repressive measures by the Legislature, means should be adopted to instruct parents as to the harmfulness of these products when given to very young nurslings.

A French law forbids anyone under the threat of heavy penalties, from giving infants under one year of age any form of solid food unless ordered in writing to do so by a qualified doctor. Some such law in this country would prove of great service and would restrain the attention of the ignorant and foolish who thrust into the mouths of infants to their great detriment such articles as carrots, gin, bacon, beer, pudding, tea, cakes, and meat.

Another factor in infantile mortality is not infrequently the extreme poverty of the parents; the expenditure for milk in some instances is not more than one penny a day, and I have known it to be as low as half that amount. An infant, of course, cannot thrive on such a meagre allowance, and properly administered *outdoor* relief should in such cases be

given to the mother and should carry with it the knowledge that the doctor can be consulted should the child fall ill.

Medical students should be taught children's diseases and infantile disorders at the children's hospitals and undergo an examination therein before obtaining their diplomas. They should not be allowed, as at present, to practise the medical profession without having made themselves thoroughly acquainted with the care and treatment of infants. That our future medical practitioners should be so educated that they will be in a position to give sound medical advice to the public on infantile and childish ailments is most important.

It follows, therefore, that the reduction of the present high infantile mortality rate is a complex social problem, and demands the adoption of a variety of remedial measures and the hearty co-operation of all classes of the community to bring about a successful result.

The perils at man's hand that beset the infant to rob it of life and health from its advent into the world are numerous and deadly.

Infant life and infant health are national assets of far-reaching importance—how important to England in the future no man can foresee. Has not the time arrived for the Legislature to prescribe appropriate remedies to safeguard its future citizens, wealth-producers, and protectors?

OCULAR THERAPEUTICS. (a)

By SYDNEY STEPHENSON, M.B., F.R.C.S.E.

(Continued from Page 138.)

LECTURE II.

2.—MYDRIATICS.

We may first usefully distinguish between "mydriatics"—that is, agents capable of causing dilatation of the pupil—and "cycloplegics"—that is, agents capable of paralysing the ciliary muscle and consequently the function of accommodation. Every cycloplegic with which I am acquainted is also a mydriatic, but the converse proposition, as we shall see immediately, is not true, or is true in a restricted sense only.

The two groups, cycloplegics and mydriatics, serve different purposes. Broadly speaking, the first-named are employed before estimating refraction, whereas the last-named are used to dilate the pupil in disease or to facilitate full ophthalmoscopic examination of the media or the fundus of the eye.

The agents that act mainly upon the musculature of the iris and affect the ciliary muscle scarcely at all are three in number—cocaine, euphthalmine, and mydrine. On the other hand, those that paralyse the ciliary muscle, together with the sphincter of the iris, are four in number—atropine, homatropine, eumydrine, and the methylbromate of atropine. I leave out of account several other agents that act in the one way or the other, such as scopolamine, duboisine, daturine, hyoscine, atrosine, picramine, and hygrine, because there is still some doubt with regard to their chemical composition, and few of them, except perhaps scopolamine, seem likely to render any great practical help in eye work.

Let us suppose that we desire to dilate the pupil, for the purpose of obtaining a satisfactory view of the fundus oculi with the ophthalmoscope. Atropine is about the last drug that a progressive ophthalmic surgeon would employ, because his experience tells him that the resulting disturbance in sight would be considerable, and would persist for several days. On the contrary, he would use a mydriatic pure and simple. Until the last few years cocaine was practically the only agent at our command which would dilate the pupil moderately and yet produce no considerable or lasting effect upon the function of accommodation. Even

that agent now and then played us false, and caused an uncomfortable dimness of sight. Modern pharmacy, however, has again stepped in, and supplied us with *Euphthalmine*, a mandelic acid derivative, the hydrochloride salt of which appears in the form of a white crystalline powder, soluble in cold water. It may be used to dilate the pupil simply as a 3 per cent. to 5 per cent. aqueous solution, although its action in that direction is heightened and hastened by the addition of cocaine hydrochloride, 2 per cent. The mixture, moreover, is somewhat cheaper, since it allows the lower percentage of euphthalmine (a very costly drug) to be employed. A few drops of this combination placed in the conjunctival sac will cause the pupil to dilate in about thirty minutes, with a minimal effect upon the function of accommodation. The dilatation passes away in a variable time, which averages about four hours, a process that may be quickened by applying a drop of physostigmine, 0.5 per cent., to the eye after the examination is completed. It will be gathered from what has been said that euphthalmine, alone or mixed with cocaine, is the agent to employ when it is desired to dilate the pupil for purposes of ophthalmoscopic examination without causing anything beyond trifling discomfort to the patient.

Mydrine is a compound of ephedrine and homatropine hydrochlorides, and when used as a 10 per cent. solution acts in the same way as euphthalmine. It is, however, a mixture, and, so far as I know, presents no single advantage over the last-named agent. The pupil, moreover, retains its action after mydrine has been used, and the amount of dilatation is less than after euphthalmine.

The important point to bear in mind is that after the employment of either euphthalmine or mydrine patients may be assured that they will be able to transact their business as usual, which is certainly not the case after atropine has been dropped into the eye. Mydrine solutions, it may be added, are very stable.

With regard to atropine, I have no new facts to bring under your notice, except perhaps the claim lately made by Dr. T. K. Hamilton (*Ophthalmoscope*, May, 1905) that the annoying conjunctivitis and dermatitis sometimes produced by it may be obviated by employing a solution of chlorotone as the vehicle instead of ordinary distilled water, and of Dr. W. G. Sym (*ibid.*, April, 1905) that the same end may be attained by using the alkaloid dissolved not in water at all but in pure olive oil.

Eumydrine.—This new mydriatic, which occurs as a white powder, readily soluble in water, has been investigated by Goldberg (*Heilkunde*, 1903) and by Lindenmeyer (*Berl. Klin. Woch.*, November 23rd, 1903). According to the former observer, a 1 per cent. solution acts more promptly than atropine (1 : 1,000), and its effects pass away more rapidly. No injurious results have been noted. Eumydrine, indeed, is stated to be fifty times less poisonous as regards the central nervous system than atropine, from which, by the way, it is obtained. Eumydrine acts as a trustworthy cycloplegic. Lindenmeyer found the new agent to be of service in such inflammations of the eye as would ordinarily be treated with atropine.

Speaking for myself, I have employed eumydrine in a solution containing two grains to the ounce of distilled water, and have satisfied myself that it is a speedy, painless, and trustworthy mydriatic. Complete cycloplegia follows its use. It differs in two important points from atropine. First, the paralysis of accommodation induced by eumydrine instead of lasting for upwards of a week as with atropine, usually passes away in the course of two or three days. Secondly, its action both upon the pupil and the ciliary muscle may be neutralised in half an hour or so by means of a weak solution of physostigmine (0.5 per cent.). This is not possible after atropine has been employed.

In the course of my experiments with eumydrine I have been impressed by one point, namely, that it is usually an excellent substitute for atropine when

(a) Lectures delivered June 1906, at the Polytechnic, London.

appearances of local intolerance to that remedy are present. In order to bear out this somewhat important practical observation, I may briefly quote one or two illustrative cases. (1) Jessie H—, æt. 12, was ordered atropine (grs. 2) on July 4th, 1904, as a preliminary to estimating a considerable error of refraction. After four applications of the atropine drops the child's face became red. When seen on July 8th, the eyelids were puffy, and, like the neighbouring parts, red and angry-looking. The skin of the eyelids, when grasped between the fingers, conveyed a parchmentous feeling. There was dried muco-purulent discharge about the eyelids. A solution of eumydrine, grs. 2 to the ounce, was substituted for the atropine. The new drops were used twice a day until July 25th, without setting up the least irritation. (2) Maria M—, æt. 60, was ordered atropine drops (gr. 1 to the ounce) on August 8th, 1904, on account of choroiditis accompanying high myopia. A fortnight later (August 22nd) she presented herself suffering from extensive atropine irritation of the eyelids and neighbouring skin. The affected skin was parchmentous, dry, shiny, and red. The patient complained bitterly about the drops that had been given to her. Eumydrine (grs. 2) was substituted for the atropine. A week later the patient was free from all symptoms of irritation, and the eumydrine has produced no discomfort at all. (3) Emily G—, æt. 18, ordered to both eyes atropine drops, grs. 4 to the ounce, on December 12th, 1904. After one application, the skin on the left side of the face, as far as the level of the nostril, became red, swollen, and tender, and "seemed tight." Furthermore, she was only just able to open the eye. Eumydrine, grs. 4 to the ounce, acted well upon the pupils, and produced no irritation, though used three times a day for three days. (4) The effect was not so happy in the fourth case, that of a young woman, who was affected with bilateral interstitial keratitis, the result of inherited syphilis. In that case the usual type of irritation was induced by atropine, duboisine, hyoscyamine, and by eumydrine. It is, however, the only instance of the kind I have met with.

The slight poisonous qualities of eumydrine lead me to think that it may prove useful in children for paralyzing the accommodation before estimating the static refraction of the eye, and that in certain cases where the long-continued employment of a mydriatic is desirable—for example, in squint, interstitial keratitis, and so forth—it will be found to offer some advantages over atropine.

Methylbromate of Atropine.—This product occurs as white crystals freely soluble in water. It is, like eumydrine, a good substitute for atropine. Its action depends upon its strength. A 1 per cent. solution produces rapid dilatation of the pupil accompanied by cycloplegia. But combined with 1 per cent. cocaine it dilates the pupil without having much effect upon accommodation.

General Conclusions with regard to Mydriatics.—In certain inflammations of the eye, as iritis and iridocyclitis, no mydriatic, except perhaps eumydrine, can, according to our present knowledge, equal atropine, employed either as the sulphate, grs. 2 to grs. 4 to the ounce of distilled water, or as a solution of the alkaloid of the same strength in olive or castor or sesame oil. To dilate the pupil in suspected iritis for the purpose of ascertaining whether adhesions exist, it is better to select some agent, as the methylbromate of atropine, the effects of which pass off rather quickly. For estimating refraction in children atropine sulphate (grs. 2 to grs. 4) is at present in almost universal use, although it may well be replaced by eumydrine, on account of the slight toxic properties of the latter. A similar remark is equally applicable to cases where the long-continued employment of a mydriatic is called for. For estimating refraction in adults, atropine, in general, should be avoided, and recourse be had to homatropine and cocaine, each 2 per cent., to eumydrine, 1 per cent., or to atropine methylbromate and cocaine, each 2 per cent. To enlarge the pupil for ophthalmoscopic examination,

mydrine, 10 per cent., or, better, a mixture of euphthalmine and cocaine, of each 2 per cent., should be adopted. Atropine is absolutely contra-indicated under the circumstances. Remember, finally, that atropine is not the panacea it is sometimes believed to be for almost every inflammatory affection of the eye. When in doubt do *not* prescribe that drug. No mydriatic agent whatever, no matter how quickly its effects pass away, should ever be used in grown-up persons until tension has been estimated with the finger and glaucomatous cupping of the optic disc has been excluded by a glance with the ophthalmoscope.

3.—MYOTICS.

In physostigmine and pilocarpine respectively, we have two agents capable of contracting the pupil, the former energetically and the latter in a milder way. The salicylate of physostigmine has been recommended by Dr. T. K. Hamilton (*Ophthalmoscope*, May, 1905) as a particularly suitable salt for prolonged use in chronic glaucoma. A substance named isophysostigmine, another alkaloid of the Calabar bean, has recently been investigated by Ogiu, a Japanese oculist (*Die Therapie der Gegenwart*, November, 1904). That surgeon found that the drug acted more quickly upon the pupil, and with greater energy, and for a longer period than physostigmine. These claims, if substantiated are likely to lead to the general employment of isophysostigmine. Another comparatively new myotic, Arecoline, has fallen under my personal notice. It is one of the several alkaloids of the betel nut, and used as the 1 per cent. solution of the hydrobromide salt, has rendered service in glaucoma. By several observers, Mr. Richardson Cross, of Bristol, among the number, it is considered to be the best myotic for general use. But according to the younger Galezowski (*Recueil d'Ophthal.* XXV., 1903, p. 112) even a half per cent. solution now and then gives rise to irritation of the conjunctiva.

4.—ANÆSTHETICS AND ANALGESICS.

Anæsthetics may be defined as agents capable of rendering the eye insensitive to the pain of surgical operations, while analgesics are agents capable of obtunding any pain that may exist. The distinction between the two classes comes out very clearly in eye work, when we compare the action of two such medicaments as cocaine and dionine. The former, when dropped into the eye, renders the superficial parts insensitive, but has no definite influence upon the deep-seated pains of, say, iritis and glaucoma, whereas the latter deadens such pains without at the same time rendering the parts insensitive.

The anæsthetic for choice is still cocaine hydrochloride, as a 2 per cent. watery solution. In actual practice, however, it still leaves something to be desired, and to some extent, especially in America, it has been replaced by a 1 per cent. solution of the hydrochloride of holocaine. Holocaine, it is true, has advantages over cocaine. For example, it is a pure local anæsthetic, without action of any kind, sort, or description upon the pupil, accommodation, tension, or corneal epithelium. For the relief of deep-seated ocular pain, as Hinshelwood has pointed out (*British Medical Association*, 1898) it is greatly superior to cocaine. My personal experience has convinced me that it has bactericidal powers, and, further, that it is better absorbed by a reddened eye than is cocaine. Its only drawback is that owing to its toxic properties it cannot safely be injected into the lachrymal passages or beneath the conjunctiva or the skin.

Dr. Carl Koller, who brought cocaine under the notice of the profession twenty-one years ago, has lately made a practical suggestion with regard to its use in cataract and other operations upon the eye (*Ophthalmoscope*, September, 1904). One or two minutes after placing a few drops of cocaine in the conjunctival sac, he injects 2-3 drops of a 5 per cent. solution beneath the ocular conjunctiva at the spot where he intends later to apply the fixation forceps. Five minutes afterwards, operations upon the eyeball, even such as involve the iris, can be performed without pain. I cannot help thinking Dr. Koller's suggestion

has not yet had the attention paid to it that it deserves.

Eucaïne lactate is a white powder, readily soluble in water. Its sole action is to induce local anæsthesia. For use in eye work, Langaard (*Therapeutische Monatshefte*, August, 1904), who regards the new agent as a substitute for cocaine, recommends a 2 per cent. or 3 per cent. solution, combined, if necessary, with adrenaline.

After a tolerably extensive trial of a 2 per cent. watery solution of eucaïne lactate, I have reached conclusions regarding its action upon the eye that may be summarised as follows: the agent has no action whatever upon the pupil, ciliary muscle, or epithelium of the cornea. It produces neither redness nor anæmia of the superficial parts of the eyeball, nor does it give rise, as cocaine often does, to retraction of the upper eyelids. Its effect upon tension is nil. It sets up about the same amount of smarting when placed in the eye as cocaine—certainly not more, as Ellis (*California State Journal of Medicine*, Vol. III., No. 5) has stated. Thus, twelve adult patients æt. 27 to 77, had a drop of 2 per cent. cocaine placed in one eye and of 2 per cent. eucaïne lactate in the other, and the discomfort was greater in the first eye in two instances, in the second eye in five instances, and was equal in the two eyes in five instances. Finally, local anæsthesia of a satisfactory nature is quickly induced, three minutes sufficing for the purpose, according to the mean of twenty experiments. In some cases of pain from irido-cyclitis and other causes, the discomfort was lulled for an hour or more by a few drops of eucaïne lactate. In short, my personal experience confirms Langaard's claim that in eucaïne lactate we have an agent whose sole action is to produce local anæsthesia. Additional good points about the new remedy are its ready solubility in water, its comparative cheapness, its relative non-toxicity, and the fact that it undergoes no appreciable change when boiled, so that it may be kept sterile for an indefinite period. Further trials should be made with this interesting product, which possesses, as we have seen, some decided advantages over cocaine.

A good deal of attention, especially in France, has lately been paid to another local anæsthetic, the discovery of Fourneau, called Stovaine, the hydrochloride of amyline B.P. It occurs in small white flakes, is extremely soluble in water, and its chemical reactions are almost identical with those of cocaine. Its solutions are not altered by boiling until a temperature of 120° C. has been reached, clearly an advantage from a practical point of view. Coakley (*Medical News*, April 15th, 1905) finds that the aqueous solution can be boiled for an hour without undergoing the least change, and that the stovaine can then be recovered intact by simple evaporation. The toxicity of stovaine is equal to one-half or one-third, that of cocaine being represented by one.

My experiments were made with a 4 per cent. watery solution of stovaine hydrochloride. I have found that it is a good local anæsthetic, and I have now performed a fair number of operations under its influence. Its action is that of an almost pure local anæsthetic, although retraction of the upper eyelid and slight dilatation of the pupil may follow its application, as pointed out by Fromaget and Dion and myself (*Ophthalmoscope*, November, 1904). Accommodation, however, is not affected. In a 1 per cent. or 2 per cent. solution it is very suitable for injection beneath the conjunctiva before operating for squint, removal of a piece of iris, or cataract. In brief, I conclude that in stovaine we have a trustworthy and relatively non-toxic local anæsthetic, and one capable of ready sterilisation by boiling, and as such I commend this latest product of synthetic chemistry to your notice. It may be combined with cocaine or adrenaline, and there are some reasons for thinking that the admixture acts better than the individual drug. In the treatment of disease, stovaine may be combined with other remedies, as ammoniated mercury or yellow oxide of mercury, in an ointment. But in that event the general rule applies,

namely, that the alkaloid itself must be used and not a salt. A similar remark applies to oily menstria.

Yohimbine, an alkaloid from Yamabeboea bark, has enjoyed a reputation for a few years as an aphrodisiac. Magnani, Salomonsohn, Loewy, and Muller have employed a 1 per cent. solution as an ocular anæsthetic. Claiborne and Coburn (*Medical News*, July 9th, 1904), who used a 2 per cent. solution, concluded as the result of their experiments that yohimbine, in addition to being a local anæsthetic, caused smarting and suffusion of the eye, moderate dilatation of the pupil, and slight blurring of sight, due not to paresis of accommodation but to spherical aberration. The high price of yohimbine, together with the fact that it is not a local anæsthetic, pure and simple, will militate against anything like its general employment.

An analgesic of practical importance has lately been introduced in the shape of Dionine, the hydrochloride of ethyl-morphine, a white powder, soluble in water, and employed in eye work as a 1 per cent. to 10 per cent. solution. It has little if any action on superficial structures, as conjunctiva and cornea, thus differing markedly from cocaine. When dropped into the eye, especially of children and unhealthy adults, it not infrequently gives rise to pain, chemosis, and swelling of the eyelids, and, by finding its way into the nasal passages, to sneezing—"ophthalmologic fireworks," is the expression applied by Dr. A. B. Hale (*Ophthalmic Record*, December, 1903) to describe these untoward effects of dionine. After use for some days (two or three usually) reaction of the kind described either fails to appear altogether or manifests itself in a trivial way.

The changes alluded to, which are more striking than dangerous, are ascribed to an inundation by lymph of the tissues of the eye, and this lymphagogue property of dionine has been utilised for the removal of inflammatory products; such as opacities of the cornea and the lenticular remains after cataract operations. Bulson (*Ophthalmic Record*, August, 1904) writing on this subject, says: "In fact, the remarkable results secured by dionine in clearing the pupillary space following cataract extraction has led to the belief that, with the more or less general employment of dionine after cataract extractions secondary operations will be greatly lessened in number." Time alone can show whether this claim can stand! Dionine is useful in interstitial keratitis in hastening the absorption of corneal deposits late in the history of the disease. In this condition I have myself obtained excellent results. In such cases there is, as usual, a right and a wrong way of using dionine. The right way is to drop a 5 per cent. solution into the eye three or four times a day for a couple of days, and to repeat the process after waiting some three days. In children I have cured many septic ulcers of the cornea, associated with pus in the anterior chamber, by simply dropping dionine into the affected eye.

Darier has pointed to another and even more practical use of the new product—namely, the induction of analgesia lasting for several hours in some of the more painful affections of the eyeball, as episcleritis, hypopyon-keratitis, irido-cyclitis, and glaucoma. This action is most useful, since agonising pain may often be calmed by the simple expedient of applying to the eye a few drops of a 5 per cent. solution of dionine. In acute iritis, especially when of "rheumatic" origin, I often prescribe: Atropine sulphate, grs. 2; dionine, grs. 5; water $\frac{1}{2}$ oz.; the liquid to be used two to six times a day, according to circumstances. Dionine may also be combined with physostigmine or pilocarpine in the medical treatment of glaucoma. A useful combination is—physostigmine sulphatis, gr. $\frac{1}{2}$; dionine, grs. 5; water, drachms 4.

Blanco (*Archivos de Oftalmologia*, August, 1904) has successfully treated two cases of intra-ocular hemorrhage by means of the subconjunctival injection of dionine.

As a symptomatic rather than as a curative agent, dionine is well worth the earnest attention of practising physicians. In my experience, it is a most efficient analgesic. For the relief of deep ocular pain the 5 per

cent. solution should be employed every four to six hours, according to the particular circumstances of the case.

One other analgesic remains to be mentioned, viz., Acoine, the employment of which for rendering subconjunctival injections painless or almost painless has been alluded to earlier in these lectures.

General Conclusions as to Anæsthetics and Analgesics.—To my thinking, the ideal anæsthetic or analgesic should fulfil three requirements: first, it should exert simply an anæsthetic or analgesic action, as the case may be; secondly, it should not irritate the eye; and, thirdly, it should be readily soluble in water, economical in price, and non-toxic in use. Bearing these various points in mind, it will be found that the best agents to employ preliminary to an operation on the eye, named in their order of merit, are holocaine, 1 per cent.; eucaine lactate, 2 per cent.; stovaine, 4 per cent.; and cocaine, 2 per cent. For injection, holocaine must be carefully eschewed, and the preference be given to stovaine, 1 per cent.; eucaine lactate, 1 per cent. or 2 per cent.; or cocaine, 1 per cent. or 2 per cent. To obtund deep-seated pain in the eye, irrespective of its cause, we use dionine, 5 per cent.; combined in iritis with atropine and in glaucoma with physostigmine or pilocarpine. To render subconjunctival medication as little painful as possible, acoine, 1 per cent. or 2 per cent. is the agent *par excellence*.

AN EFFECTIVE ARMY MEDICAL RESERVE FOR THE AUXILIARY AND REGULAR FORCES. (a)

By SURGEON-COLONEL P. B. GILES,
F.R.C.S., V.D.,

Staff Medical Officer, 30th Field Army Brigade, and of the Volunteer Ambulance School of Instruction.

FOR the best interests of the nation the relationship between the regular and auxiliary medical services should be as intimate as can be between co-ordinate bodies. The old idea that the regular medical service (R.A.M.C.) should only be sufficient to administer to a mixed force of 80,000 troops was rudely disillusioned at the commencement of the late war; this fallacy was exploded, and it is certain, however apathetic the country may be at the present moment, should another big war occur with similar unpreparedness, that the nation would demand a day of reckoning, and that a severe one. The easiest, and in the end the cheapest, policy is to prepare for war during the piping days of peace. It is silly after a war has broken out inquiring, Where is the medical reserve when, as a fact, even in peace, the field strength of the R.A.M.C. is deficient? There is only one way to create a potential and effective Army Medical Reserve, and that is to utilise the auxiliary medical services. The way to effect this is simple, the cost comparatively little. Take the cost of those who die, or are disabled from preventable causes during any, or all, of our campaigns, as compared with that which will follow the present admirable system adopted by the Japanese.

The auxiliary medical services should be developed so that its personnel could supply all the duties of the R.A.M.C. as high as that of principal medical officer, so that in the event of a war in which all the officers of the R.A.M.C. were required out of England, there should be officers of the auxiliary medical service qualified to perform

their duties. This may seem a big order, yet comparatively little extra training would accomplish it. The method is simple. First, the auxiliary medical service, as I have urged for years, must be made a reality and not merely a force on paper. That this is a possibility the practical results of the labours of the late D.A.D.-G., Colonel Wilson testify; for whilst engaged in the organisation and supply of the R.A.M.C. during the late war, he was able to develop a practical scheme for volunteer bearer companies. If all units of the auxiliary forces were brigaded, and proper brigade medical companies were recruited and welded into a concrete auxiliary service (R.A.M.C.V.) the chief difficulty would be overcome. By brigade medical unit I mean a unit capable of performing the duties of a field hospital, a bearer company, and the sanitary or preventive disease work of a brigade, such as I have advocated in papers read at the meetings of the British Medical Association, and such as I have practically used for years in brigade camps. In such units officers and men should be allowed when they changed their localities to be transferred. Secondly, the regimental stretcher-bearers should be a reality, and not, as they now so very frequently are, a force existing, or not, upon the caprice of the officer commanding. It should be a *sine qua non* for obtaining the annual grant that a complete section holding A.F. 596 parade under the medical officer.

All medical officers of units should when gazetted to their unit pass automatically into the R.A.M.C.V. because:—First, during the late war great numbers of volunteer medical officers were refused attachment for service to the R.A.M.C. because it was stated the officer commanding their units had control of them. Secondly, by so doing all but one medical officer in each unit would be at the disposal of the surgeon medical officer for duty other than regimental. Thirdly, because then the most suitable could be utilised with his unit; it is ludicrous to see a Surgeon-Lieutenant Colonel doing regimental duties in the field when his Surgeon-Lieutenant is on duty in hospital. Fourthly, because this system would permit of free exchange in those cases in which the medical officer changed his residence.

This plan would produce a concrete body co-ordinate with the R.A.M.C. which proper training would enable to take over most of the duties of the R.A.M.C. when required at a time of national danger. In the time of peace there should be a volunteer medical officer of the rank of Colonel at the Medical Department of the War Office. He should be the Director-General's adviser on volunteer medical subjects, and generally supervise the service. In each command there should be a volunteer Lieutenant-Colonel, who should similarly represent his service, and should inspect and report upon the medical efficiency and requirements of the R.A.M.C. volunteers and units, and should appoint Boards to examine for A.F.E. 596 and A.F.E. 624.

As at present, all volunteer medical officers should be examined for their A.F.E. 564, but in addition to those who by attending at Aldershot, who, if successful, receive an allowance for attending, and who up to the present can be counted upon the fingers of one's hands, similar daily allowances should be granted to those officers who attend (and pass) at the Volunteer Ambulance

(a) Paper read at the Royal Institute of Public Health, London Congress, July, 1905.

School of Instruction, which has taught and passed 700.

Later, when the volunteer medical officer has passed and obtained field rank, then, if he desires further advancement, it should be compulsory for him to attend for a month at Aldershot, Netley, &c. If my ideas, or modifications of them, were adopted, there would be at once—fairly trained on the lines of the R.A.M.C. and accustomed to discipline—a large body of men sufficient to form a real Army Medical Reserve. In time of war this Army Medical Reserve could be fed by civilian trained men, such as St. John's Ambulance, who would come having had elementary instruction in their future duties. There is no doubt that the priority given to firemen and St. John's Ambulance men during the late war was prejudicial to the best interests of the volunteer medical service. The idea that civilian aid is to supplement the regular medical forces in war is wrong, chiefly because it is neither so well trained nor disciplined, and has this anomaly, that the military authorities are more or less hampered by civilian bodies, who do not hesitate to employ private influence to obtain the better treatment of their respective organisations.

Clinical Records.

CASE OF NEURITIS OF THE LEFT ULNAR NERVE FOLLOWING AN ATTACK OF PNEUMONIA, WITH DRY PLEURISY ON THE SAME SIDE. (a)

By MAJOR EMILE ROUYER, M.D.,
Of the French Army Medical Service.

THE occurrence of paralysis and neuritis following pneumonia has long been recognised, and the subject was fully dealt with in the graduation theses of Boulloche and Jonakieff. In the experience of these authors the cases may be divided into two distinct categories, according to the date of the appearance of the paralysis, which is sometimes early in onset, occurring at the very commencement of the attack or during the period of maintenance of the disease; in others, the paralysis supervenes during defervescence or convalescence.

The case I am about to relate belongs to the latter category. It is unfortunately incomplete owing to the fact that the patient was treated in a small garrison town where no means were available to investigate the various electrical reactions. He was one of five children, all alive and in good health. His mother died of inflammation of the lungs and his father from a gastric (?) affection. He had never been ill before, but stated that as a child he was very liable to headache, the attacks ceasing at the age of puberty. He was left-handed. He joined the army in November, 1899, and was passed as of sound constitution and lymphatic temperament. He did his first few months' service without any difficulty, but in July, 1900, he was admitted to hospital suffering from a moderate attack of left lobar pneumonia, after which for several months we could hear pleural friction. This was treated by counter-irritation, and in December, 1900, he appeared to be quite well.

On February 22nd, 1901, he came complaining of tingling in the fourth and fifth fingers of the left hand with vague pain in the left shoulder. It was noted that the ring and little finger were semi-flexed, though they could be easily extended. In the course of the next few days the flexion became more pronounced, and there was resistance on trying to straighten the fingers. At the same time the tingling was associated with lancinating pain from the hand to the shoulder. On March 1st, the "ulnar claw" was distinctly

present. He was transported to the military hospital at Belfort, where he underwent a course of treatment by electricity and left much improved. He was given two months' holiday.

On his return to the regiment on June 13th, he was in the same state. The ulnar claw was still well marked. The first phalanx of the fourth and fifth fingers was in complete extension, and the two last phalanges in complete flexion. All attempts to straighten the fingers failed and caused pain. At the same time the thumb was drawn back by the extensor, and could not be opposed to the other fingers by reason of the paresis of its adductor muscle.

The sensory troubles were purely subjective. He still complained of tingling in the left arm, and on the slightest exertion he experienced sharp pain from the shoulder to the tips of the fingers. No hyperæsthesia, no anaesthesia, nor delay in the transmission of sensation. The temperature of the left hand was lower than the other, and the skin over the tips of the fingers was livid. No trophic disturbance, and there was no obvious atrophy of the arm, but we must bear in mind that the patient is left-handed.

I left the garrison soon after, but I am informed that the neuritis has persisted unchanged in that there had been no change for the worse. I may add that this patient, who was under close observation for several months, never presented any sign of pulmonary tuberculosis, his general health remained good, and he had gained in weight since his return to the regiment.

Observations of ulnar neuritis following pneumonia are not often met with in military hospitals where pneumonia usually assumes a frank aspect. Busquet, in his work on the subject, does not mention pneumonia as one of the affections capable of leaving peripheral nervous lesions behind it. After all, there is nothing surprising that the toxins of the pneumococcus should act like those of Eberth-Löffler, or the streptococcus; indeed, it may be, in the case under consideration, that some importance should be attached to the pleural friction noted during convalescence from the attack of pneumonia. I may add that Déjérine, in his article in Bouchard's treatise on pathology, mentions a case of neuritis of the ulnar nerve following influenza, and refers to the same lesion as having been observed by Nothnagel, Bernhardt, Pitres, and Vaillard after typhoid fever.

British Medical Association.

SEVENTY-THIRD ANNUAL MEETING, JULY 24TH TO 28TH.

[FROM OUR SPECIAL CORRESPONDENT.]

THE SURGICAL SECTION.

THE first day's meeting of the Surgical Section was for the most part devoted to a discussion on the "Surgical Treatment of Non-Malignant Diseases of the Stomach." This was opened by Mr. B. G. A. Moynihan. He considered first the subject of acute perforating ulcer. Excision of the ulcer at the time of operation he held to be unnecessary, the necessity for lavage of the peritoneum and drainage he looked upon as determined by the time which had elapsed since the perforation. He performed gastro-enterostomy when the ulcer was near the pylorus and the infolding involved some narrowing of the latter, and he advised washing out of the stomach with the stomach tube. In cases of serious hæmorrhage from the stomach he had found gastro-enterostomy the safest and surest method of arrest. This he explained on the ground that when the stomach is emptied and collapsed the hæmorrhage tends to cease spontaneously. In chronic ulcer of the stomach he considered that the question of operation should be considered early, the results now obtained by operation showed that for this condition the treatment should be surgical and not medical; the mortality was less, the results were better, and the risks from lethal complications were avoided. Gastro-enterostomy was the operation he preferred, and also the same procedure for hour-glass stomach; for the latter condition, however, other methods were sometimes necessary.

(a) *Bulletin Medical*, March, 1905.

Professor Saundby expressed the opinion that stomach conditions were pre-eminently those in which the co-operation of the medical and surgical elements in consultation were desirable. Hæmorrhage from gastric ulcer he considered a condition that rarely called for operation; he had never had a fatal case. A large proportion of cases of gastric ulcer were curable by medical means, although where the ulcer heals and constriction or adhesions follow, the indication for surgical assistance could not be disputed. He dissented from the view that all cases of chronic inveterate dyspepsia should be surgically explored. Many of such cases were of nervous origin with atonic dilatation, and were made worse by operation.

Important contributions to the discussion were those by Professor Hartmann, of Paris, and Dr. Finney, of Baltimore. The former considered gastro-enterostomy generally the best operation in the treatment of non-malignant stomach diseases; the mortality of his last 47 cases had been 6 per cent. He thought this would be lower if French physicians would advise the operation in time, which was unfortunately not the case. The complications he had had were chiefly pulmonary, and he considered the care of the mouth during the days previous to operation a matter of importance. In pyloric stenosis and moderate hæmorrhage recurring many times patients were cured by gastro-enterostomy, the remote results were also good in intractable ulcers not cured by medical treatment. He did not agree with those who held that excessive hæmatemesis needs an operation. The operative mortality of such cases was high, and the cure by medical means frequent. He, however, operated in all cases of small and repeated hæmatemesis.

Dr. Finney first described the operation of pyloroplasty of which he published a description in 1902. He now performed this operation in preference to gastro-enterostomy. In 25 cases of his own he had had a mortality of three. He had collected 112 cases from the literature with a mortality of 8.9 per cent.

Mr. Mansell Moullin, in operating for chronic ulcer, always excised whenever possible, in addition to performing gastro-enterostomy. He thought that the proportion of cases of chronic ulcer which formed the basis of carcinoma was usually under-estimated.

Mr. F. S. Eve thought excision of a chronic ulcer was unnecessary and usually impracticable. He attached importance to a thorough examination of the interior of the stomach in all cases. He performed posterior gastro-enterostomy. Pyloroplasty he had only performed once, and the pyloric constriction had recurred later.

Mr. Rutherford Morison did not think that gastro-enterostomy was likely to maintain its present position. He preferred pyloroplasty whenever possible.

The other speakers dwelt chiefly on the advisability of extending the sphere of surgical treatment in non-malignant stomach diseases. Posterior gastro-enterostomy was preferred to the anterior operation by the majority, and most also appeared to agree with Mr. Moynihan when he said that pyloroplasty, that is to say, the Heinecke-Mikulicz operation, was dead. Mr. Moynihan held, however, that the Finney operation was a good one, and that the choice of the future lay between this and posterior gastro-enterostomy.

On Thursday, July 27th, a discussion on the "Surgical Treatment of Malignant Disease of the Rectum" was introduced by Sir Robert Ball. He pointed out how trivial were the symptoms in the early stages of the disease in many cases, and emphasised the necessity for digital examination in all rectal complaints. When the colon could be properly emptied before operation, he considered colotomy unnecessary and objectionable. Perineal excision he adopted only when the anal canal was involved. In some cases he performed partial excisions, that is, in growths involving only part of the circumference of the bowel. In the sacral operation he removed the coccyx along with part of the fifth sacral vertebra. He thought that the method of bringing down the bowel and suturing to the natural anal canal denuded of its mucous membrane was the

one which promised the best results. In two of his own cases a small portion of the gut sloughed in two instances, but an excellent result was eventually obtained. In three cases which had been operated on by the abdominal route he had been able to finish the operation in the same way. The abdominal route he considered offered several important advantages in estimating the extent of the disease, arresting hæmorrhage and clearing out lymph glands, and he thought that many cases which had been treated by trans-sacral excision would have given a better result by this method.

Mr. Swinford Edwards had found the aero-proctocolotomy of value in diagnosis. He favoured preliminary colotomy when the peritoneal cavity was likely to be opened, and when there was likely to be a large faecal accumulation. Where preliminary colotomy had not been done he always endeavoured to avoid opening the peritoneal cavity. He performed partial excision in some cases when the disease was limited to the posterior or postero-lateral wall.

Professor Hartmann said that he had operated on 64 cases of rectal cancer since 1896, 43 by palliative operation. In 21 cases treated radically he had had one death. In cancers above the anus he brought the rectum down through incisions surrounding the anus, and continuing on to the left side of the coccyx, which he removed. After freeing the rectum and opening the peritoneum, the margin of the bowel above the growth was brought down and sutured to the skin. He had obtained in this way twelve recoveries in twelve cases; three had had recurrence after six, seven, and eight months.

Mr. Stanmore Bishop said that he had given up all operations from the perinæum alone. In the sacral operation he preferred end-to-end union of the bowel.

Mr. T. G. Atkins thought that in the future many more cases would be operated on by the abdominal route. In operating by the sacral route he finished the operation by inserting a Paul's tube into the proximal end.

Mr. Sinclair White showed a specimen in which a rectal diverticulum was attached in the neighbourhood of a cancerous mass. He avoided colostomy in elderly patients if the disease was quite recent, but resorted to it in others. He had had one death from peritoneal infection in a case of removal by the vagina. Of 26 cases five had died from the operation; nine of those who had recovered had been operated on more than three years ago, four of these were free from recurrence three years after operation. He had decided to give up the sacral route for the abdominal.

Mr. E. Deanesly always removed the whole of the rectum saving the anal canal, wherever possible, and brought down the sigmoid to the denuded anus.

Mr. Mitchell said that he was in the habit of commencing operation by separating the anal mucous membrane and ligaturing the tubular process thus formed to prevent faecal contamination.

Mr. C. Ryall thought that an examination under an anæsthetic should always be made before deciding that a growth was too fixed for removal. During operation the greatest care should be taken not to tear the growth or cancerous material might be implanted in the wound.

Mr. Jackson-Clarke said that in high rectal cancer complete removal of the rectum through the abdomen and the bringing of the sigmoid flexure to the anus was now giving better results than the sacral operation.

The majority of the speakers who took part in the discussion held that a preliminary colostomy was unnecessary. No series of statistics comparing the abdominal and sacral routes was put forward, but it was a general opinion that the abdominal route would gain in favour in the future. The method of Mon-longuet of bringing the upper end of the bowel down to the anal canal denuded of its mucous membrane was that generally preferred in finishing the operation, and the inconveniences of the sacral anus was commented upon by several speakers. Mr. Lynn Thomas said that he preferred an inguinal to a sacral anus.

On the third day, a number of papers were read. Mr. J. W. Thompson Walker showed an important specimen obtained from a patient who had died of cancer of the bladder, and who two years previously had had his prostate completely enucleated by the suprapubic method. It showed a small cavity where the prostate had been, and a complete absence of any tendency to stricture.

Mr. C. B. Keetley read a paper on "Appendicostomy," and stated that he considered the operation of value in certain cases of chronic constipation, for mucous colitis, in syphilitic ulcers of the colon, and in some cases of intussusception.

Mr. J. Berry showed a number of patients on whom he had operated for cleft palate, and tables relating to sixty-seven cases. He kept to the old operation, preferred to operate in the third year, and expressed strong disapproval of Brophy's operation.

Mr. W. J. Wheeler reported a successful case of the Talma-Morison operation for hepatic cirrhosis.

Mr. J. Jackson-Clarke read a paper on "Congenital Dislocation of the Hip." He stated that he had obtained very good results by the Lorenz manipulative method, since he had seen the method practised by Lorenz in 1903. Mr. Jordan Lloyd said that he thought the functional results were not so uniformly good as some surgeons were inclined to represent, and that parents should not be allowed to take too rosy a view of the prospects of the method.

THE ANNUAL EXHIBITION.

THE Exhibition was located in the Drill Hall and Magazine Square in the ancient and picturesque portion of Leicester called the Newarke. The firms exhibiting numbered over a hundred, and the excellent catalogue formed a substantial guide-book of 155 pages. Mr. Guy Elliston, the Secretary of the Association, acted as manager of the Show. Generally speaking, the Exhibition was well arranged. We were pleased to find that aggressive wine and spirit merchants and other undesirable non-medical traders had been diminished, although not entirely excluded. The troublesome intrusions of showmen, often pronounced in previous years, were but little noticeable at Leicester. Altogether the Exhibition struck us as being a fairly representative one, and on the whole judiciously conducted, and we trust the self-repression and courtesy of the exhibitors will have brought them rich rewards.

In the space at our disposal, it is only possible to mention briefly the newer and more important of the exhibits. Many firms of manufacturing druggists were well represented. Messrs. H. and T. Kirby and Co. displayed "Purgen," a comparatively new non-irritating purgative; "Glycocols," or soft glycerine lozenges containing heroin, codeine, and other drugs; various tablets of compressed drugs, and their useful Pocket Pharmacopœia of selected remedies. Parke, Davis and Co. showed their excellent adrenalin preparations, thyroidectin, acetozone, a non-toxic antiseptic, their well-known Cascara compounds, "eudrenine," the new local anæsthetic and hæmostatic, and other of their well-established and widely-used products. Special reference should also be made to their new all-glass aseptic nebuliser, which appears to be convenient, effective, and economical. Messrs. James Woolley, Sons and Co., of Manchester, made an excellent show of their goods, including Akoethe, cataplasmin, an effective form of poultice in which the hygroscopic properties of glycerin are present with the reducing action of potassium iodide, ethereal antiseptic soap, sol. sodæ phenatis, an antiseptic and sedative solution used in dental operations, and other well-approved preparations. Wyleys, the widely-known manufacturing chemists of Coventry, exhibited ruscol, a new organic compound of bismuth and birch tar, useful in dermatological work; neuracetin, an agent for relieving pain and reducing temperature; various heroin compounds, and many medicinal syrups, liquors, and other elegant pharmaceutical preparations. Messrs.

Andrus and Andrus showed their much-advertised hemabroids; formolyptol, a pleasant formaldehyde preparation; and kola-cardinette, a new and elegant cordial and stimulant. The Bayer Co. made a brave show with their many mysterious synthetical and fancifully named preparations, including argyryr, aspirin, the very useful heroin, jothion (containing 80 per cent. of iodine), somatose, tannigen, trional, and veronal. The Angier Chemical Company exhibited their well-known petroleum emulsion with hypophosphites. Fairchild Brothers and Foster displayed their "Fairchild Digestive Products"—Lecithin, "Peepsenica," "Panopepton," and their various "zymine" preparations. The latter are now to appear in tablet form under the name of "pepule." Arthur and Co. exhibited Bromaurum and a number of cosmetic applications. Messrs. Burgoyne, Burbidges and Co. displayed a selection of their goods, including Calodal, Collargol, Creosotal, Duotal, Salocreol, Xeroform and other well-established medicaments. Philip Harris and Co., of Birmingham, showed many useful pharmaceutical specialities, including Ehrendorfer's pencils of iodoform, and a series of excellent concentrated mixtures. Messrs. Newton, Chambers and Co. had many manifestations in solid and liquid form of "Izal." Messrs. Oppenheimer, Son, and Co. pushed their "Palatinoids," and their convenient "Aseptules" of renaglandin were again to the front. Messrs. C. J. Hewlett and Son had a goodly show of elegant preparations, including the well-known Mist. Pepsinæ Co. c. Bismutho, Mist. Terpin Heroin Co., Lin. Betulæ Co., Antithermogen, a useful antiseptic and absorbent, and "Creosalgen," a powerful antiseptic. The Charles H. Phillips Chemical Company displayed their mild neutraliser of hyperacidity and convenient laxative, "Milk of Magnesia." Messrs. T. Howard Lloyd and Co., of Leicester, exhibited many useful preparations—Saphthol, an antiseptic soap powder; Malto-Eastonii, effervescent "solulettes," "ocules," most useful in ophthalmic work; and the very ingenious and convenient "inklets," or compressed ink tablets, which we are ourselves using with great satisfaction. The Jeyes' Sanitary Compounds Company displayed "Cyllin" in all its many formed glory.

Foods and food products, as usual, monopolised much space and clearly showed that the problems of diet and nutrition were far from being solved. The Maltine Manufacturing Company, in addition to their many "Maltine" preparations, exhibited the well-known Carrick Liquid and Beef Peptonoids. Cheltine Foods and Chocolate, Limited, displayed various forms of "food," biscuit and bread, and their malted milk-chocolate appeared to be particularly nutritious and palatable. Brand and Co. were well advertised in their many compressed and concentrated juices and jellies. The Manhu Foods Company made a speciality of diabetic preparations. Keen, Robinson and Co. did not allow us to forget the benefits of Robinson's Patent Barley and Groats, so much desired by infants and invalids. Moseley's Food, introduced by Foods Limited, of Stockport, is a new claimant for popularity and certainly after fully testing it we can testify to its highly palatable and nutritious properties. Cadbury is a name which almost forms an integral part of the British Constitution, and the well-known cocoa and chocolate of this firm are too greatly prized to need more than a passing reference. Van Abbott and Sons, and Callard and Co. showed samples of their starchless and sugarless preparations, which are certainly useful in many cases of diabetes and obesity. Horlick's Malted Milk had an extensive stand where samples were very freely provided. M. Hoff, of Hamburg, displayed his malt extract and palatable tonic, "Ironal." Broomfield and Co. showed Albene, the vegetable fat. Henri Nestlé was to the front with the widely used condensed milks and comparatively new "Milo" food. The Aylesbury Dairy Company made a good exhibit with their various milk preparations, and "Pollyta," a new solid milk food for infants. Mellin's dietetic preparations also had a stand. "Virol" and

"Bovril" were both well represented. Armour and Co., of Chicago fame, exhibited their various glandular extracts in powder and tablet form, and preparations of thyroid extract, soluble beef and other meat products, for which they are justly celebrated. The "Veda" bread and oat food appeared to be particularly palatable. Reynolds' Wheatmeal Brown Bread was also exhibited. The Shredded Wheat Company had a complete demonstration of their methods of preparation.

Various waters and beverages were conspicuously represented. Among the waters reference should be made to the well-arranged exhibits of Vichy, Carlsbad, Contrexeville "Pavillon," Wildungen, Vittel, Apenta, Apollinaris, Johannis, Perrier, and Friedrichshall.

This year's Exhibition was particularly noteworthy on account of the many excellent displays of surgical goods, hospital appliances, and sanitary equipments. Messrs. Down Brothers showed all their new forms of hospital furniture and surgical instruments. Arnold and Sons had an excellent exhibit of many fresh surgical instruments. Mayer and Meltzer displayed their latest appliances for laryngological, rhinological, and otological work. Lynch and Co. showed many medical appliances and hospital apparatus. Messrs. John Weiss and Son had a useful exhibit of the newest improvements in surgical instruments. Messrs. Allen and Hanbury showed the new cerebro-spinal manometer, suggested by Mr. F. C. Eve, the uterine dilator of De Sergneux, and other novel appliances. Messrs. S. Maw, Son, and Sons had a representative display of instruments. C. A. Hoefftcke displayed various forms of orthopædic appliances and artificial limbs. T. Holland and Son also showed their specialities for weak feet. Messrs. J. Defries and Sons exhibited a model of the Equifex Steam Disinfecter, and many preparations used in disinfecting, pasteurisation, and also forms of the celebrated Pasteur filters. Pocock Brothers had put up a very elegant padded room, fitted with aluminium gutter, self-acting shutter, protected door-hinge, and complete in every particular. Young's Hygienic Bin Company showed a large collection of galvanised steel bins most useful for hospital purposes. "Ronuk," Limited, the sanitary polish manufacturers, showed their special polishes and staining which are now used very extensively in hospitals and public institutions. The Cellular Clothing Company exhibited various forms of Aertex cellular clothing. D. T. Bostel and Sons had an interesting exhibit of their various patterns of the "Bostel Fire." The many forms of the "Lawson Tait" bedstead were well exhibited, and other varieties of bedsteads were shown by John and Joseph Taunton, the Longford Wire Co., and Isaac Chorlton and Co., of Manchester, the latter firm having on view the new "Lloyd-Smith" Sanatorium Chair. G. H. Zeal showed the useful and accurate "Repello" clinical thermometer. Messrs. Smith and Wade had an interesting exhibit of their Multinebuliser or compressed air outfit. Slack and Brownlow demonstrated the advantages of the "Brownlow" Filter, in which water passes through cylinders of porous porcelain. The Dowsing Radiant Heat Company had an extensive stand at which the benefits of their system were well demonstrated. The Sanitary Wood Wool Company exhibited the now well-known and widely used "Hartmann" dressings. The Liverpool Lint Company also showed various forms of tissue, gauze, sheeting, and other surgical requisites. A. De St. Dalmas and Co., of Leicester, had a good collection of medical plasters and surgical bandages. A number of exhibitors showed electrical appliances and X-ray outfits.

It was interesting to note that stands had been taken by the Buxton Urban District Council, the Borough of Royal Leamington Spa, and Harrogate and Buxton Corporations, for the distribution of handbooks recording the climatic and other advantages of each as a health station.

A very good number of firms exhibited motors suitable for medical practitioners, among them being Humber Limited; the Central Motor Car Company; McNeil, Hutchison and Co.; T. H. Wathes and Co.;

the Clyde Motor Company; and the Rykniel Engine Company.

Comparatively few medical publishers were represented, but stands were filled by Mr. H. K. Lewis and W. S. Saunders and Co.

France:

[FROM OUR OWN CORRESPONDENT.]

PARIS, August 12th, 1905.

IMMEDIATE TREATMENT OF RETENTION OF URINE.

ACUTE retention of urine from different causes requires prompt treatment. The usual cause is due either to stricture, to hypertrophy of the prostate, or to acute gonorrhœa.

In cases of stricture the passage of a fine bougie is indicated, and around which the patient will urinate. The passage of this small bougie is frequently very difficult, and great patience, says Dr. Cathilin, is necessary. The penis must be drawn well forward and the bougie screwed in, so to speak, until the obstruction is passed.

It may be often necessary to insert three or four bougies up to the stricture, and one of them will finally pass through the small orifice, which is frequently excentric. This bougie will be left *in situ* twenty-four hours, when gradual dilatation may be commenced.

* In patients suffering from hypertrophy of the prostate, a large catheter *à bougille* should be used, and when the bladder is reached it should be left *à demeure* three or four days, by attaching it to the hair on the pubis. The bladder should not be emptied completely, only six ounces of urine drawn off, and if it appears to be infected, four ounces of a solution of nitrate of silver (1 in 1,000) should be injected. The plug of the catheter should be taken out every hour or two to allow the patient to urinate.

In the acute stage of blenorhagia, medical means should be preferred to the catheter; diuretic infusions, warm enemas, warm applications over the hypogastrium, warm baths, opium, &c.

In cases where, in spite of repeated attempts, the catheter cannot pass into the bladder, recourse must be had to tapping the bladder with a fine trocar above the pubis.

The point of election is the median line between the symphysis and the pre-vesical cul-de-sac of the peritoneum, and done with the usual precautions the operation is devoid of danger. The instrument to be used is that of Dieulafoy, or, preferably, Potain's aspirator. In this last case, the proper working of the apparatus should be proved beforehand. The needle (No. 2) should be passed through the flame and placed in a solution of phenic acid. The patient is laid on a table and pubes soaped, shaved, and disinfected. With the nail of the index finger of the left hand the operator marks a point on the median line at about half-an-inch from the symphysis, and, seizing the trocar with the right hand, he plunges it in at the exact spot marked by the finger of the left hand, perpendicularly and without fear. As soon as the bladder is penetrated, a sensation of vanquished resistance is felt. Aspiration is then adopted, and the liquid flows into the bottle.

The bladder should not be completely evacuated, for fear of provoking congestion of the bladder, or even intra-vesical hemorrhage, and in order to avoid the penetration of some drops of urine into the cellular tissue, the aspiration should be suppressed before withdrawing the needle.

TREATMENT OF INFLAMMATION OF THE MIDDLE EAR.

Acute otitis of the middle ear in infants, children, or adults is always a grave affection, and claims immediate attention. In infants the diagnosis of otitis presents sometimes considerable difficulty, and in certain cases it is impossible.

In the course of some acute affection, the child cries and moans for several hours or all night. Nothing seems to soothe it, and the mother, alarmed, sends for the doctor, who, after minute examination, fails to discover the cause of the trouble. One or two days

afterwards, however, a drop of pus is found on the pillow, to the astonishment of the parents and the physician. The child is calm, sleep has taken the place of agitation and all ends well.

But, says Dr. Dubar, there are cases where the pus, not being able to find an issue through the tympanus, invades all the cavities it meets and reaches the meningeal membranes by the sutures, producing meningitis. With the first symptoms of the malady a few drops of

Olive oil sterilised, 2 oz.;

Resorcine, $\frac{1}{2}$ drachm;

should be injected into each nostril by means of a syringe, while a plug of cotton steeped in

Resorcine, 15 grs.;

Phenic acid, 5 grs.;

Glycerine, $1\frac{1}{2}$ oz.;

should be placed in each ear. The same treatment should be employed with elder children, while with adults the antiseptic of the nasal fossa is realised with the following ointment:—

Stovaine, 4 grs.;

Menthol, 6 grs.;

Phenosalyl, 1 gr.;

Vaseline, 5 drachms;

Lanoline, 3 drachms;

Weak antiseptic gargles should be renewed several times a day in order to clean out the Eustachian tube.

As soon as any painful sensation is felt in the ear in the course of some infection, five or six drops of

Resorcine, 15 grs.;

Phenic acid, 15 grs.;

Glycerine, $1\frac{1}{2}$ oz.;

should be poured into the ear. When suppuration occurs the ear should be treated by a small plug of antiseptic gauze inserted as deeply as possible by means of a probe, and renewed daily if possible. Irrigations or irritating antiseptics should be avoided.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, August 12th, 1905.

At the Medizinische Gesellschaft. Hr. Greef brought forward the

STATE CAMPAIGN AGAINST TRACHOMA.

He pointed out the great importance of epidemics of trachoma, especially in war time. That the cases in Berlin were only isolated did not lie in absence of local disposition. In East Prussia, a part that was settled by the Swabian introducer, Frederick the Great, and who had never intermixed with the surrounding population, there was no trachoma amongst them, although they were surrounded with the disease.

Since the Government campaign against trachoma had become organised no marked diminution in the disease had been proved. But in spite of this the pessimism that it had called forth was out of place. On the Rhine and in Southern Germany the disease that was very widespread in the last century had almost disappeared.

In the Eastern provinces, along with a general raising of the culture, an improvement in the water supply had been beneficial. Fresh water must be readily accessible with people so that several may not have to wash in the water used by persons suffering from the disease. What ophthalmologists can do for granulations had been taught by the Rhine statistics. Such eye surgeons were still wanting in the East. It would be necessary to support them by State subvention.

Hr. Herzog demanded the institution of a commission to inquire into the origin of trachoma, as well as the continuance of courses of treatment and regular examination at school. The improvement in wages was important, so far as to make people remain on the land, and thus avoid the influx of foreign agricultural labourers amongst whom trachoma was always present.

Hr. Kirchner reported that since 1898 more than 2,000,000 marks had been spent on the trachoma

campaign, and not only the number, but also the severity of the cases in East Prussia had very materially diminished in that period. At the commencement some uniformity of view had to be formed amongst surgeons; by institution of courses of teaching medical men were brought to distinguish trachoma from the severe follicular catarrhs of the conjunctiva. Further, a systematic examination of all school children was undertaken, the diseased children were segregated from the others, and the further spread of the disease was prevented by improvement in hygienic conditions and especially in the erection of new school buildings. Village sisters were appointed at the cost of the State.

A great difficulty lay in the institution of "season workers," and this had its origin in that German spirit of wandering. The East Germans wandered to the West, and therefore labourers from Russia, Poland, and Galicia had to do the work, to return to their own countries after the harvest. They introduced diseases with them,

But in spite of all this they had succeeded in limiting the disease in East Prussia, and it is to be hoped that in other Eastern provinces (Silesia, Posen, and West Prussia) they would succeed as well, and so much the more as the new law, with its duty of notification, its compulsory treatment and disinfection, afforded powerful weapons that they had not hitherto been in possession of.

At the sitting of the Aertzeverein Reg. Bez. Stralsund, Hr. Glimm showed a number of patients who had been

TREATED FOR CARCINOMA OF THE SKIN BY X-RAYS

First as regarded the method of treatment.

Generally speaking soft tubes were used; hard tubes only in the case of thicker tumours and metastases under the skin. In small tumours the distance between the tumour surface and that of the tube was 5 ctm., with large ones 12 ctm. Importance was attached to a high number of interruptions with a weak current. The surrounding parts were protected by lead plates $\frac{1}{2}$ mm. in thickness. Preference was given to one sitting lasting up to 90 minutes; shorter, repeated sittings were only made use of where the portion of the tumour and pain did not permit of the longer application. Over-dosage was avoided by the use of Holzknecht's chromo-radiometer, so that no burning on the skin took place in any way. Ten cases were treated, in most of which the cancerous nature of the disease was confirmed by the microscope. Five of these were carcinomata of the lip, four operable cases, cancer of the face, and one of inoperable cancer of the shoulder, with metastases 22 ctm. in length on the neck, breast, and arm. Smooth and complete recovery took place in eight cases. In one case of cancer, occupying nearly the whole of the lower lip, recovery took place only after a piece had been excised from the middle, that part being too thick for X-ray treatment. The inoperable carcinoma of the shoulder healed locally, the metastases also disappeared, but they returned. Of the eight first-named cases five after one application remained free, one after ten months. In the other three cases recurrence took place in 3, $3\frac{1}{2}$ and 5 months; in only one case, however, was operative removal required. The last case shown was one of very large lupus, carcinoma of the cheek; after $5\frac{1}{2}$ weeks' treatment there was already considerable improvement.

In conclusion he pointed out the following indication for X-ray treatment:

In the front rank were those cases of carcinoma of the skin, the removal of which by operative measures leaves unsightly scars and disturbs or destroys functions.

In the second came inoperable cases of mammary carcinoma, as amelioration of pain could always be procured and generally diminution in size of the tumour, with occasionally disappearance of all metastases.

Whether recurrences would be more frequent after X-ray treatment we should have to await further experiences for a decision to be reached.

Hr. Friedrich remarked that notwithstanding his scepticism regarding the treatment of carcinoma by X-rays, yet after the reliable reports of cases he felt that he had to prove it in the Greifswald klinik. Up to the present only superficial growths (many recurrent nodules therefore) had been accessible to the treatment; deep-seated neoplasms and especially those of the intestinal tract were absolutely excluded.

In mammary carcinoma also if the case were operable he always operated, preferring the certain to the uncertain way, whilst recurrences of many kinds could often be favourably affected by X-ray treatment. It was remarkable how pain in the vicinity of recurrent growths near nerves was favourably influenced occasionally. However dazzling the success in the cases demonstrated he uttered a warning against illusions in carcinoma in other situations.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, August 12th, 1905.

MYXO-SARCOMA.

LORENZ brought a young lad, *æt.* 13, before the members of the Gesellschaft, who was operated on four days previously for a malignant myxoma, which had embedded itself in the folds of the mesentery, destroying all the glands in its immediate surrounding. Its root was attached to the small intestine, which had to be removed, along with the growth, making a total of 220 cubic centimetres extirpated. The microscopical examination confirmed the diagnosis and justified early operation. The patient is now in a very promising condition.

Eiselsberg said that he had a very similar case about a year ago, occurring in a girl, *æt.* 12, on whom he operated without any sign of recurrence up to the present time. He was, however, inclined to characterise his own case after the microscopical examination as a lympho-sarcoma, and not a myxo-sarcoma as Lorenz had done.

OSTEBITIS DEFORMANS.

Latzko demonstrated another of those isolated cases put forward by Katholicky some time ago as not uncommon. The patient was *æt.* 35, with the whole skeleton in a form of transformation. Around the eyes were great barriers of osseous deposits as well as other parts of the cranium. The extremities were greatly deformed. This deformity had gone on since he was nine years of age, and was still proceeding in spite of all efforts to check it.

Latzko thought there was one symptom pathognomonic in this osseous thickening which distinguished it from osteomalacia or multiple myoma, viz., the great thickening of the corticalis.

Latzko further presented two other cases of puerperal sequelæ on whom he had operated. The first was a long firm band of fibrous tissue—not a thrombosed spermatic vein as he emphasised, but a firm band of fibrous tissue.

The second was endometritis septica necessitating supravaginal extirpation of the uterus with a retroperitoneal pedicle.

SPINAL ANALGESIA.

Preleitner next gave the members his results and recommendations for operating with these so-called analgesics. He thought this form of operation best suited for children where heart failure and dangerous bronchitis was often produced by the inhalation of chloroform. Again, the patient being conscious swallows any offending matter which might under gas be carried into the lung and produce pneumonia. Lastly, no narcotiser is required with the operation, which is often a great advantage.

The objections raised against this form of operating are the temporary after-constituents of the urine associated with incontinence.

In the discussion, Clairmont said he had now performed forty operations by the spinal analgesia method, and met with incontinence five times only. This

incontinence is probably due to the formation of a hæmatoma.

Eiselsberg was more cautious in the use of these analgesics and warned operators of their dangers in the lumbar region. He finally asked if there were any real need for such a risky operation.

Fraenkel thought the spinal analgesia was only a minor part of the operation, as the very sight of operating filled the child with terror and excitement to get free from its persecutors. To his mind, it was more important to remove psychical quality than the algesic. He had not seen a child operated on under this local anæsthesia, but presumed the child could not be easily controlled.

Preleitner assured Fraenkel that the child lay quite quiet and often asleep when the operation was going forward. His own opinion was that the pneumonia in children was a serious factor to deal with, and could be avoided under spinal analgesia. Again, the incontinence is not due to a hæmatoma but rather to the action of the eucain.

Operating Theatres.

THE FRENCH HOSPITAL.

THE QUESTION OF SEARCHING FOR THE APPENDIX IN ACUTE ILLIAC ABSCESS.—MR. EDMUND OWEN operated on a governess, *æt.* 20, who on admission was extremely ill, and exhausted by constant vomiting. She had had an attack of appendicitis five years before, but had been quite healthy ever since. Three days previous to her coming to the hospital she had been suddenly taken with acute pain in the abdomen and vomiting. On admission her temperature was 102°, and her pulse was 120. Her bowels had not been moved for three days. The abdomen was distended, rigid, and did not move on respiration. A fulness, which was very tender could be felt in the right iliac region. She was at once taken into the theatre and operated on. The appendix, which was gangrenous, was removed, and a large abscess was found extending from it into the pelvis. There had been no attempt whatever on the part of Nature to wall off the abscess, but the pus was bathing the coils of intestine in the lower part of the abdomen, and was welling down into the pelvis around the uterus and bladder. The pus was mopped up with swabs of gauze, and the operation was completed by the insertion of a large drainage tube into the bottom of Douglas's pouch.

Mr. Owen remarked that it was by no means rare to find a foul abscess tracking without delimitation amongst abdominal and pelvic viscera, and that although, of course, the condition was a desperate one, still, if the cavity and its soiled contents were well cleaned out with dry swabs, and efficiently drained, the cases did well. A recognition of the fact that so large a proportion of these desperate cases recovered, had made him much bolder in his search for the appendix in those operations in which a mere incision of an abscess did not reveal its presence. At first he used to content himself with opening the abscess, and making but a timid search for the appendix, which if found, was promptly removed. To leave diseased appendix unremoved was always a source of regret to an operator, yet often the surgeon had unwillingly to come to the conclusion that it was, on the whole, safer not to search for it. But a diseased appendix unremoved was an ever-present source of danger, and though, after having given rise to one acute abscess it often gave no further trouble, still the

patient would have been far safer without it. The majority of persons who had apparently entirely recovered after an incomplete operation upon an acute appendicular abscess were disinclined to be again put upon an operating-table in a quiet interval, in order that the lurking appendix might be removed. And though in most instances the appendix gave no further trouble, still, at any moment, it might again cause an alarming conflagration. Taking, thus, all things into consideration, Mr. Owen had become more aggressive in his dealings with acute appendicular abscesses, and was fully satisfied with the way in which the end had justified the means. The presence of an acute appendicular abscess, he remarked, apparently caused most of these patients to spontaneously undergo a process of auto-immunisation against the toxins set free by the growth of the septic micro-organisms, and though one would not desire to search for the diseased appendix in the acute stage, it was nevertheless, in many of these anxious cases the right course to pursue.

The patient made a rapid and complete recovery.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5 0s. 0d.; Half Page, £2 10s. 0d.; Quarter Page, £1 5s. 0d.; One-eighth, 12s. 6d. Considerable Reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the Publisher.

Small announcements of Practices, Assistantships, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and Colonial subscribers at 21s. per annum, post free, if paid in advance, or 22s. 6d. credit rate.

MISTAKEN DIAGNOSIS.

UNDER the heading of “Mistaken Diagnosis,” newspaper readers are being somewhat widely entertained in the waning journalistic season. It is obviously the duty of the lay journalist to keep his finger on the pulse of the public so as to learn therefrom the diet likely to prove most attractive to his audience, needless to say, quite apart from its wholesomeness. From long experience he has learnt that anything derogatory to medical men forms a subject of perennial catch-penny attractiveness. Why the public should love to hear of the shortcomings of a profession to which they owe so much is somewhat of a mystery. But so it is, and the fact that “nearly” 2,000 cases of mistaken diagnosis occurred last year in patients admitted to the Metropolitan Asylum Board hospitals has been hailed with delight by jaded sub-editors. Unlikely as it may seem the matter was brought before the public by

a medical man, Professor W. R. Smith, chairman of the Statistical Committee of the Board. To that statement he added the calculation, based upon a period of average detention of three weeks, that the total cost of these erroneous notifications to the ratepayers reached £12,000 for the year. As a former medical officer of health, Dr. Smith must be fully alive to the fact that a margin of error is inseparable from the circumstances of the case. It is important from many points of view to isolate an infectious patient in the early stages of his malady, that is to say, at the very time when it is most difficult to form a really trustworthy opinion as to the precise nature of the disease. German measles is not infrequently mistaken for scarlet fever, and a few weeks since we heard of it being pronounced enteric fever, with the result of the infliction of a vast deal of unnecessary anxiety and expense to the friends, and of injury to the reputation of the medical attendant. This latter complication is not likely to occur where private patients above the hospital class are concerned, for the medical attendant is able to give a guarded opinion and await further developments. But when the patient has to be hurried off to a hospital he has to act upon observation that is often inadequate, and at times absolutely misleading. Atypical cases of specific infective fevers are of constant occurrence. For instance, let the average man in the street think of the appalling nature of the pitfall presented by a case of measles or of scarlet fever without rash. Then again the earlier stages of enteric fever are often suggestive of anything but the real malady. We have personally known men of the highest eminence in the profession, men whose lives have been spent in the conscientious study of medicine in hospitals, and medical schools, who have made disastrous errors in the diagnosis of typhoid fever. In other words, medicine has not yet attained the position of an exact science. Nor, so long as the conditions of experiment vary, does there seem any prospect of getting rid of fallacy in the notification of disease. The disease itself varies so greatly that its usually characteristic features may be marked or absent, the constitution of the patient varies, the experience of the medical man varies; in short, precise data are often not available upon which to form a reasoned conclusion. In what are called “typical” cases, there is no suggestion, so far as we know, that many errors are made. That general practitioners do make, and will always make, a certain number of errors when called upon to form definite conclusions upon imperfect grounds is natural and excusable. It would be more to the point were Professor Smith to inquire how many errors were made by members of the hospital medical staffs. He appears to assume that the latter are absolute, just as there is no appeal against the finality of their diagnosis. As a matter of fact we believe that even under existing circumstances most favourable to an accurate and deliberate diagnosis such mistakes do occur.

Obviously it is extremely difficult to get to the facts of such occurrences in the Metropolitan Board Hospitals. Applying our argument based upon the unavoidable margin of error involved, such mistakes must obviously follow on the part of the hospital medical staff which sits in judgment on the general practitioner. On the whole there seems little wisdom or tact in obtruding matters of this kind which are unavoidable, but which cast a gratuitous slur upon an honourable profession.

THE TRUE RE-ORGANISATION SCHEME OF THE I.M.A.

THE misleading manner in which the proceedings of the re-organisation committee appointed by the Council of the Irish Medical Association were reported in the *Journal* of the association for July, is bearing fruit, as is shown by a resolution passed by the Cavan branch. This branch entirely disapproves of the majority report "which would do away with branch representation," but it agrees with the minority report recently issued. So far from the majority report doing away with branch representation, it proposes that the election of branch representatives shall be an essential condition of branch existence; indeed, up to the present, there has been no branch representative—nor in the so-called minority report has any proposal for branch representation been made. It is true that 32 county councillors are selected, and the minority propose to curtail this system: but the county councillors are not elected by branches, nor need they be proposed by them. They can be nominated by any member of the association, and are elected by the members in each county, whether they belong to a branch or not. The majority report proposes that the General Meeting shall be the governing body of the association; that the vicious system shall cease, by which the Council is nominally the governing body, but which actually vests the entire control in a Committee of Council, which has brought the association to the verge of a financial crisis, and which, as was demonstrated in the Evatt case, over-rides the Council and sets its authority at naught. We wonder if the Cavan branch has considered the absurd Committee of Council suggested by the four dissentients: A president, who every second year shall be a country member, and may not be able to attend regularly; four vice-presidents, also unable to attend; one honorary secretary; and one co-opted member. By such an arrangement the entire working of the association would practically pass into the hands of the honorary secretary and of the co-opted member. We do not blame the Cavan branch for falling into error as regards the proposal of the majority of the re-organisation committee, nor for assuming that the documents conceived and issued by the minority without the knowledge of, or consultation with, the other mem-

bers of the committee, was really a minority report—an assumption probably due to the statement in the July number of the *Journal* that there "voted for the county representative scheme Drs. Delahoyde, Donnelly, Hickey, and Tobin." The Cavan branch could not know, that neither this nor any county representative scheme was ever submitted to, or voted on, by the committee. What was before it was Dr. Donnelly's scheme of grouped branches (*vide* page 201, *Journal*, July) and this, after very careful examination by the committee was found to be unworkable. We fear that among the many pressing needs of the association is a scheme by which the editing of this *Journal* will be amended. It is not too much to expect that its statements of facts should at least approach accuracy, for it is most necessary that the official organ of an association should report accurately its proceedings and should support loyally the policy of the association.

MEDICAL EXAMINATION OF VOLUNTEERS.

MR. ARNOLD FORSTER must by this time be very sorry he issued his ill-advised circular, and its hardly better-advised supplement, ordering a general medical examination of the Volunteer Forces with a view to ascertaining their fitness for foreign service. Not only is the examination resented by the men, and a distasteful addition to the medical officers' duties, but it has been shown to be clearly *ultra vires*. To get out of the awkward position in which he had placed himself, the Secretary for War has had to resort to those ingenious devices of logomachy which have become so fashionable in high political circles at the present day. The circular directed officers commanding Volunteer corps to instruct their medical officer "to report upon the general physical standard of the men under their charge," in order that an opinion might be formed as to their fitness to serve abroad, and the requisite qualifications were set out at length. There were certain misunderstandings as to what exactly was meant by this circular, so a second explanatory one was subsequently issued. Mr. Arnold Forster immediately found that he had raised a hornets' nest about his ears, for his unfortunate circular violated not only the spirit, but the letter of the Volunteer Act, and it was obvious in so doing he could not enforce obedience to his commands. A Volunteer only takes oath to serve allegiance to the Sovereign in Great Britain, and this undertaking is further modified by the words, "according to the conditions of my service." The contract is one voluntarily entered into for a particular purpose, and the service rendered—and cheerfully rendered—is manifestly one that should be entitled to special consideration. Officials controlling the Volunteers should be the last people to overstep their authority; on the contrary, they should endeavour, as far as is consistent

with discipline, to grant every indulgence to their subordinates. The person of all others to appreciate this fact should be the Secretary for War, who, as a civilian, might be, and theoretically is, more in touch with the sentiments of the country than a professional soldier. It is, too, into the all-important matter of discipline that this unfortunate circular makes inroads, for if the head of the War Office is negligent of his instructions, what sort of obedience can be hoped for among the rank and file of a sensitive and loosely-held-together force like the Volunteers? The strain of the order comes just in the most unhappy places, because in the case of objecting Volunteers, their loyalty is apt to be questioned, and unjustly questioned. In reply to questions in Parliament, as we have said, Mr. Arnold Forster has been reduced to pitiable makeshifts to maintain an obviously untenable position, his last point being that though the circular directed medical officers to report on the general physical conditions of the troops in their charge, it did not enjoin them to make an examination of the men. To the non-parliamentary mind this seems about as useful a process as making a pie without pastry, or playing "Hamlet" without the Prince of Denmark. The order cannot possibly be carried into effect without a thorough examination of the men, and moreover, as such an examination would only be evidence of the present condition, if it is expected to be of any use as showing the number of men continuously available for foreign service it would have to be repeated annually. It is not easy to see, though the point is more debateable, in what respects a man fitted for home service would fail to be fit for foreign service, especially as in the entrance examination for recruits the medical officer will already have satisfied himself as to general physical ability and freedom from constitutional disease. The order has been widely resented both in the Volunteer force itself and among certain sections of the civil community, and what we ourselves are principally concerned with is that through an unfortunate concatenation of circumstances, a matter of such supreme necessity as the medical supervision of troops should have been brought into disrepute, some men even refusing to allow the medical officers to examine them. Such an act, if the examination were made under due powers, would be highly reprehensible, and, indeed, would be subversive of all proper discipline, but as it is, the officers have to pocket the indignity because of the blunder of their superior. Moreover, the work thrown on the medical officers themselves is very arduous as the examination of a battalion of soldiers is no light task if the work be done conscientiously; and when, as in many cases, the bulk is to be done during the annual training, this little outing, which generally constitutes an appreciable proportion of the doctor's holiday, will be turned into an incessant grind. If the examination is really to become an annual institution, it is clear that there will be but few medical men with the time

or opportunity to perform such an onerous task, and it would be well for a clear statement on this point to be forthcoming, so that Volunteer medical officers may know where they are. We agree, as all sensible people must agree, that a sick soldier is much worse than no soldier, but there are other and more statesmanlike ways of insuring against physical breakdowns than by issuing orders which are contrary to the spirit of the King's Regulations, and invite open disobedience. We hope it is not too late for some wiser course to be followed.

Notes on Current Topics.

Hospitals from Inside.

FAMILIAR as we are with hospital life from one point of view, there are some sides of it to which we are quite blind. It is, therefore, almost with the feeling of exploring an unknown land that one reads the sketch of hospital life "An In-patient" contributes to our contemporary, *The Pharmaceutical Journal*. He sets nothing down in malice, and he shows himself both observant and reflective, so that his criticisms and suggestions may be taken in good part. It is interesting to notice how "An In-patient's" mental attitude alters during his stay in hospital; from the homeless, unnerved wretch, who feels his last hope of retreat gone when, on his arrival in the ward, he has to deliver his boots to the charge of the nurse, he gradually develops into the contented and comfortable convalescent, sensible of and grateful for the cleanliness and attention, the kindness of the nurses and the stoical skill of the house surgeon. The most trying part of his ordeal to "In-patient" was the daily dressing of his wound, with regard to which he says—though surely his experience is unfortunate—"no effort is made to soothe the pain and distress." He points out, too, that "it is also a very trying and unnecessary experience to have to sit round and witness the dressing of the other inmates, sometimes un-screened." This is quite true, and is just such a point as is likely, through force of habit, to be overlooked by those responsible for ward management. Nevertheless, in spite of some avoidable faults and many inevitable discomforts, "In-patient" has no doubt that "to the majority of patients the life becomes, after the first painful days, a perfect elysium."

Beware of Sunlight.

THE ludicrous aspect in which science—or scientific pretension—is, from time to time, placed before the critical view of the mobile population of our metropolitan thoroughfares is, of course, ever and anon furnishing stimuli for the risorial faculties of our brethren of the lay Press. The liveliest opportunities for such enjoyment are necessarily furnished by the flatly contradictory statements and opinions offered by the champions of certain semi-metaphysical views of physical subjects. When such questions are of a nature which precludes the possibility of directly applying experimental tests of a decisive value, there

obviously must remain more or less marginal scope for discussion and contradiction. One of the most recent examples is in regard to the value of sunlight—physiologically and therapeutically. A correspondent of one of our lay contemporaries has been chuckling over the antagonistic views of the representatives of scientific illumination and leadership. He calls attention to the fact that not very long ago we had been hearing a great deal of the antiseptic value of sunlight, especially of the violet rays. We were told the fogs which were so prone to envelop our cities periodically, and the smoke-pall which shades off the sunlight perpetually, were hygienically most objectionable, from the fact that they it was which effectively screened off the health-giving violet rays; and we were told votaries of natural sanitation had been subjecting themselves to considerable physical inconvenience, and even discomfort, in order to take sun-baths, in the fond belief that they were administering to themselves a most excellent tonic. Now, however, strikes in a learned doctor with a volume on the subject of tropical light, who informs the startled world that broad sunlight, especially the rays referable to the violet end of the spectrum, is a most unhealthy thing. According to this hygienic iconoclast, exposure to unclouded sunlight makes languid the most vigorous human animal, damages his digestion, and generally upsets his whole internal machinery. The proper and natural environment of the human form divine is one of semi-darkness. Instead of flooding our rooms with sunlight, we should carefully shut it out. All races except Europeans know enough to come in out of the sun. And so, after all, concludes our now happy—as well as patriotic—contemporary, “our smoke and fogs are a blessing, albeit in an impenetrable disguise.”

Standardisation of Drugs.

Nor the least useful of the annual congresses which have recently taken place was that of the Pharmaceutical Association at Brighton. The pharmaceutical chemists are so intimately allied both in aims and methods with medical men, that none of their doings can be without interest, and the modern pharmacist is, like the modern doctor, a man of science and exactitude to a degree that presents a marked contrast from the state of things fifty years ago. An earnest and learned address was given by Mr. Naylor, the President, on the standardisation of drugs, a subject which, in the rush of other matters is apt to fall outside the ken of medical men, on account of the technicalities that surround it. The matter, however, is one which, though the clinician may not be able to follow it into all its ramifications, is of vital importance in the progress of medicine, and one with which he should keep closely in touch. Modern pharmacy, though relegated for the most part to the chemist and the Pharmaceutical Committee of the General Medical Council, looks

to the physician for its stimulus and for the endorsement of its results, and it is well that the painstaking efforts of the men who endeavour to place it on an exact and scientific basis should be both recognised and encouraged. Much of the discredit that has been cast on the galenicals by the pathological school is undoubtedly due to the variations that have occurred in the strengths and potencies of preparations at different times, and it cannot be too strongly borne in mind that unless all drugs are standardised, a factor of error of such magnitude is introduced into therapeutics as may vitiate all conclusions derived from clinical observation. As Mr. Naylor pointed out, some of the principal matters for determination that should be constantly watched for in the administration of medicines are whether the mixed alkaloids of a given drug act as well as, or differently from, a preparation containing the leading ingredient alone, and, again, whether an alkaloid derived from one source is similar in action to a chemically similar one derived from another. Pharmacy, said Mr. Naylor, will continue to be largely what the pharmacist qualifies himself to make it, but it will also, in response to a natural law, be entirely what the doctor demands that it shall be.

Business and Pleasure.

It may be supposed that the British doctor, like the average British citizen, appears to his neighbour of the *entente cordiale* to take his pleasures sadly, but at any rate he is now given the opportunity of doing otherwise, and of gaining a little knowledge into the bargain. The Medical Study Trips that are organised by Dr. Carron de la Carrière, of 2, Rue Lincoln, Paris, are pleasant functions, and this year a journey, under the management of Dr. Landouzy, is being planned to take in the chief places of South-West France. The trip starts from Luchon on September 1st, and an attractive programme has been mapped out in quite the best Polytechnic style, showing how every hour of the next fortnight will be spent by the “adherents.” Capvern, Bagnères-de-Bizarre, Pau, Eaux-Chaudes, Salles-de-Béarn, Biarritz, Hendaye, and many other places will be visited, the tedium of travelling, lunching, and dining being diversified by conferences on hydrotherapeutics and balneology. The beautiful country in the High and Low Pyrenees will be traversed pretty thoroughly, and by those “adherents” who do not know its charms it will be found full of interest and wonder, while to Englishmen there will be added the sense that in their little way they are helping by their presence to forward the great cause of international amity. Considering all that will be done for the party the inclusive charge—£12—seems little enough, even though it does not reach quite the level of that miracle of cheapness—“A week in Lovely Lucerne.” At any rate, to the medical man who prefers a strenuous holiday to a fortnight's golf at the sea-side, the trip may be commended, and

he can be promised that at least he will be spared any uncertainty as to how to spend his time, for the programme has been made to include even such items as "arrivée vers 6h. 20—Diner—Coucher."

A Sane Woman in an Asylum.

It seems hardly credible that in these enlightened days it should be possible to hale off a sane woman from her daily life and shut her up in a mad-house. Yet such a thing was done in England not longer ago than March, 1905—witness the circumstantial and uncontradicted evidence given last week in the Appeal Courts. The name of the lady concerned did not transpire, but she enjoys a high social position, and by a more than usually common-sense act of grace on the part of the lawyers she was permitted to appear in Court under the initials, "F. M. C." It appears that the solicitor of her family came to the sapient conclusion plaintiff was not in her right mind. He communicated that belief to the solicitor who at that particular time was acting for the appellant. The lady had an income of £3,000 a year, and had recently successfully prosecuted a divorce petition against her husband. On the very day she had arranged to draw £4,000 and pay off her debts, the two solicitors took a magistrate, a coal merchant, to her house to certify her as a lunatic. He, however, was not qualified to sign a reception order, and the signature was obtained of another magistrate, who did not even see the lady, who was promptly taken off to an asylum in a special train. The Commissioners of Lunacy released her on April 17th. We do not envy the position of the solicitors, magistrates, and medical men concerned. Although they may have acted in good faith, they have clearly hurried themselves into a position of a serious and invidious nature. The comforting feature of this sordid transaction is the decisive action of the Lunacy Commissioners.

Army Medical Service.

In the whole of that incongruous patchwork that has resulted from the efforts of successive Secretaries of State to produce an organised and effective British Army, we can at least point to a genuine advance having been initiated by Mr. Brodrick in the condition and functions of the Royal Army Medical Corps. Lord Roberts' recent revelations concerning the fitness of our forces to take the field against a European foe are discomfiting in the extreme, and though it must be left to other agencies to take steps to remove this reproach, there is one factor in the situation which affects the medical profession profoundly. We mean, of course, the statement that the resources of the Royal Army Medical Corps—in spite of all the increases that have resulted from the improved pay and status of the Corps—is only capable of ministering to the needs of a force of 55,000 men. This statement was so astounding that it was properly made the subject of a question in Parliament, and

elicited a highly unsatisfactory reply. Mr. Arnold Forster replied that the War Establishments of the Army provided for a considerable number of the medical staff being civilians, but as the numbers of these available on mobilisation were not determined, it was not possible to give figures. He was aware that the strength of the Royal Army Medical Corps was not adequate, but the Army Council were making every effort to increase it. Here we find two alarming admissions—first, that although the War Office rely on civilian medical aid in time of war, the War Minister has no idea of how many surgeons may be counted upon (and therefore presumably no machinery for this organisation exists), and, secondly, that, in spite of this expected complement of civilians, the Royal Army Medical Corps is inadequate. After the shocking, heart-rending muddle of military medical affairs in South Africa, it might have been hoped that steps would have been taken to place the possibility of anything of the kind happening again beyond the region of doubt, and now we find that the circumstances have only to be re-enacted to ensure a similar breakdown. How long will a "business" people stand conduct of this kind in their chosen representatives?

The Plague.

THE apathy of the House of Commons when Indian affairs are under discussion is proverbial, and it is not a pleasant reflection that because little or no party capital is to be made out of the details of the administration of our great dependent Empire, members allow them to pass unquestioned and unheeded. We had hoped that the efforts that have been made in one or two quarters to direct attention to the appalling waste of human life that is resulting from the increasing ravages of the plague in India, would have brought forth some definite and strong policy on the part of the India Office. The facts as regard the plague have certainly not been brought home to the public in this country, or we do not hesitate to say that they would never allow an epidemic to ravage India and carry off over a million of their fellow-subjects yearly without any steps being taken to oppose it. It may be an *opprobrium medicinae* that the methods of infection in plague are but ill-understood, but certain definite facts have already been established on which a good working start might be made. Moreover, to speak from the scientific point of view alone, an amount of material is presented to the would-be investigator the like of which he has never had before, and it is all practically being wasted. If the Indian Government are waiting a clear scientific lead, they should endeavour to obtain it by employing a large staff of investigators even if the cost were great, their present efforts in this direction being so half-hearted as to suggest that they are only acting from motives of political expediency. The plague which is decimating India, and threatens almost to overwhelm it, is not matter for fatalistic

jeremiads, but a foe to be resolutely met and conquered. It is awful to contemplate the ultimate condition of the country if its present rate of increase is maintained, and of a fall there is yet no sort of indication.

Medicine and Surgery of the Japanese Army

THE whole wondering world has been brought, or forced, to admit the astonishing advances which have been made by the Japanese within a quarter of a century in the mechanical devices and scientific methods and theories adopted—so suddenly and unexpectedly—from their Western contemporaries. In no department of science or art has this development been more electric in its velocity than in those of medicine and surgery. "Nippon the Conqueror" has bettered the teaching of her instructors; and if she has stunned the Russian foe by her skill and agility in warfare, she has made a correspondingly forcible impression on her English and American friends by her hygienic care of her soldiers in the camp and on the march, and her medical and surgical treatment of the sick and the wounded respectively. We have rarely, if ever, perused a more impressive testimonial to these facts and opinions than that furnished by the pages of Dr. Seaman's recent book, "From Tokio through Manchuria with the Japanese." It is not usual to find a patriotic citizen of the great Western Republic admit the superiority of another nation in the methods and appliances which specially call for mechanical skill and precision, combined with fertility of advice and originality; but Dr. Seaman does not hesitate to do so. Himself a surgeon, U.S.V., he served in the Spanish-American and Philippine wars, and with the allied armies through the Boxer campaign. The main object of his recent visit to the Far East was the study of the Japanese treatment of the sick and wounded in the war. After dwelling on the ravages of "the silent foe" in the campaigns in which he had previously served, he summarises by informing his readers that where shot and shell slew their thousands, microbes and insanitary conditions slew their tens of thousands. And of the latter he tells us that the Japanese have made a "triumphal conquest." "Japan is the first country in the world to recognise that the greatest enemy in war is not the opposing army, but a foe more treacherous and dangerous—preventable disease. . . . The medical officer is omnipresent. You will find him in countless places where, in an American or British army, he has no place. He is as much at the front as in the rear. He is with the first screen of scouts with his microscope and chemicals, testing and labelling wells, so that the army to follow shall drink no contaminated water." And he bitterly contrasts the six weeks of the Spanish-American war, when the mortality from bullets and wounds was 268, while that from disease reached the appalling number of 3,862, or "about fourteen to one." "Banzai Nippon!" is avowedly the theme throughout of Dr. Seaman's book. Must not every

Western lover of our profession re-echo the national war-cry?

Five o' Clock Tea.

AFTERNOON TEA has long been of all things a British institution. As a social event it is of no small importance, its shortness and informality being specially attractive to leaders of the strenuous social life. Whether in drawing-room or garden tea is a lightsome meal possessing attractive features of its own. Under the influence of the fragrant cup rigidity unbends, and who knows what confidences may not ultimately be exchanged while quaffing the gentle stimulant? There are signs, however, that the afternoon function is undergoing a slow sea change, inasmuch as it is once more assuming the character of the more homely regular meal of our grandfathers. In other words, it is becoming a less hurried and a more substantial affair. It is asserted that motor-ing is chiefly responsible for this change, at any rate among the wealthier classes of society. At the other end of the social scale, and also among many of the middle classes, five o' clock tea has never been anything else than a regular sit-down meal around the family table. For late diners this innovation may be regarded as serious, for another square meal is thereby added to a list already too long. From the medical point of view this state of affairs deserves consideration. Fortunately much meaty food is rarely consumed at tea-time, but on the other hand, there is the danger which may result from the consumption of too much tea and sugary fare. The appetite, moreover, may be rendered a trifle less keen for dinner, though there is a modern tendency to postpone still further the hour for that meal. If the tea hour snatch a few minutes' rest for the restless, it will have achieved some good for society,

Synæsthesia.

ALTHOUGH the condition known as synæsthesia is one which, up to the present, has attracted the attention of psychologists rather than of medical men, nevertheless it should not be without interest to us. The term itself is somewhat difficult to define, but it is most usually applied to the phenomenon of a secondary sensation or subjective impression accompanying an actual perception. The familiar instance of shivering at the sound of a pencil squeaking on a slate is, perhaps, as simple an example as can be given. In many cases, however, certain visual are accompanied by auditory sensations, or *vice versa*. For example, the sound of the vowel "a" may give rise to a sensation of white in one subject, of black or blue in another. The sound stimuli, moreover, which call up visual accompaniments, may be very serious. In one person it may be the vowel sounds, in another the tones of a speaker's voice or of a musical instrument. It is said indeed that some violinists have been able to tune their instruments by fixing the attention on

the colour corresponding to the pitch they are aiming at, and that singers have pitched their voices accurately by the same method. Dr. Lee Smith, of Johns Hopkins, has recently published an interesting account (a) of a family in which the condition was hereditary, occurring in a father, his five children and a niece. The father, ever since childhood, has associated a definite colour with each letter of the alphabet, some appearing white, some reddish-brown, and so on. One daughter associates colours not only with letters, but with musical tunes, and with sensations of touch, temperature and pain. The conditions in the other members vary considerably in their detail. Professor Baldwin, who has studied the condition with care, thinks that synæsthesiæ are not to be considered abnormal or pathological, but that they belong rather to the realm of the idiosyncrasies.

Damages for Drawing Teeth.

A SUCCESSFUL action for damages against the unqualified son of a dental surgeon has recently been settled under somewhat peculiar circumstances. It appeared that a Bradford cotton-spinner had suffered from excessive bleeding after tooth-extraction. Other members of the family had been troubled in the same way, and one had actually died, showing clearly the hæmophilic constitution. He was introduced to the defendant, who told him the operation could be performed without risk by means of a new American invention. Six teeth were afterwards extracted at the surgery of defendant's father. Profuse bleeding followed, and the plaintiff was under medical treatment for some time. The operator was compelled to admit that he had never qualified as a dental surgeon, and he was mulcted to the extent of £125 damages. Had he been a properly qualified man, no action could have stood against him, for it is clear that no man can be responsible for results due to such an unavoidable and accidental complication as hæmophyllia. The principle involved is that a man performing an illegal act becomes answerable for its remote consequences. If that rule were more rigorously applied it would infallibly lessen the vast amount of unqualified medical practice that is now carried on in every class of the community. Let the public once appreciate that enormous damages are obtainable for any injury done to them by chemists, bone-setters, electricians, or any other non-medically qualified persons, and the paths of such offenders will be considerably narrowed.

Medical Omniscience.

THE public, with all their partiality for specialists have a way—when it suits them—of expecting medical practitioners to possess expert knowledge in every branch of their profession. A doctor, in fact, is supposed to be a walking compendium of all knowledge embraced in medicine and the allied

sciences, and when a rare or curious accident or disease is in question he must be able to expound it as if he had all the latest details of Teutonic research at his fingers' ends. It must be confessed that a good deal of the education in certain medical schools tends rather to produce the stamp of man that would fulfil these requirements, than to turn out well-armed practitioners capable of tackling ordinary disease in its commonest manifestations. But there are limits to human capacities, and even elderly practitioners may never have seen a case of ankylostomiasis or Madura foot. At an inquest held at Sheffield on August 13th, considerable interest centred in the question as to whether the patient had died of glanders. The man was a horse-keeper who six months previously had injured his leg while attending to a pony. The wound did not heal satisfactorily, and after much suffering he died of chronic pyæmia in the Royal Infirmary. Some of the ponies in the same colliery as that in which he worked had in the meantime been found to be glandered, and there seemed to be a strong inclination to attribute the man's death to the same disease. The medical witnesses, two resident officers from the Infirmary, were both closely cross-questioned as to the cause of death, and they both had to admit that neither of them had seen a case of glanders, and that the bacteriological findings were negative. Their evidence was to the effect that the patient had died of pyæmia, and the coroner in summing up informed the jury that they had to decide what disease had caused death! The jury sensibly found in accordance with the medical evidence, feeling probably that if the doctors were unable to pronounce a case to be glanders, their own opinion was not worth much.

The Bonmartini Murder Case.

MEMBERS of the medical profession have been considerably involved in the notorious Bonmartini murder case, settled last week in the Italian criminal courts. It appears that the Countess, the wife of the murdered man, was in her earlier days attached to a medical student, but her affection was later bestowed upon the Count Bonmartini, whom she married. The marriage eventually became unhappy, and finally a separation took place. The brother of the Countess was Tullio Murri, son of the distinguished ophthalmic surgeon, Professor Murri. Inflamed at the real or supposed wrongs of his sister, Tullio formed a plot against the life of Count Bonmartini, and after vainly attempting to get the help of her lover, Dr. Secchi, he secured the active assistance of Dr. Naldi. The upshot of the affair was that the unfortunate Count was found stabbed in the Bologna Palace some three years ago. The crime has at length been brought home to five persons. Tullio Murri and Dr. Naldi have each been sentenced to thirty years' solitary confinement and ten years' police surveillance. Dr. Secchi and Countess Bonmartini were condemned each to ten years' solitary confinement, and a servant who was

(a) *Johns Hopkins Hospital Bulletin*, July, 1905.

an accomplice to seven years. Tullio Murri was publicly denounced as the murderer some time ago by his father, the Professor. The terrible nature of the sentence is hardly realisable by those who are unfamiliar with the methods of Italian prisons. Inhuman and barbarous as our own penal system may be, it is a thousand times preferable to the gehenna of the Italian convict.

SIR SYDNEY WATERLOW, at the Hospital Sunday Fund meeting last week, moved the adoption of the report of the Committee of Distribution which had been circulated to the council. The fund will not be closed till the end of October, and the contributions at the present time amount to £75,000. The generosity of Mr. George Herring and the £12,500 received under the will of Wyndham Francis Cook make the collection this year a record amount. Since the fund has been instituted, £1,382,160 has been collected for the benefit of hospitals. It is proposed to distribute the sum of £71,466 among 162 hospitals and 60 dispensaries, as shown in the appendix to the report, and Sir Sydney Waterlow moved that the awards be paid as soon as possible.

PERSONAL.

The seventh meeting of the International Congress of Hydrology, Climatology, Geology, and Physical Therapeutics will be opened at Venice on October 10th, under the honorary presidency of the Italian Minister of Public Instruction, and the acting presidency of Professor A. De Giovanni, of the University of Padua.

THE offer of Sir Alfred Jones, of the Liverpool School of Tropical Medicine, to send Professors Ronald Ross and Rubert Boyce to the Mayor of New Orleans to deal with the outbreak of yellow fever in that city, has been gratefully accepted.

PROFESSOR BOYCE sailed last Saturday on the "Campania" to investigate the epidemic of yellow fever at New Orleans.

THE appointment of Dr. Alexander Cruikshank Houston as director of water examinations, Metropolitan Water Board, at a salary of £1,000 per annum, is announced. Dr. Houston is an Edinburgh graduate and took the degrees of M.B., C.M., in 1889; B.Sc. (Public Health) in 1891; and D.Sc. (Public Health) in 1892.

MR. GERALD BALFOUR has promised a deputation who waited on him last week to have inquiries made by special officers of his department in the various centres where the rate of infant mortality was abnormal, and to consider their report carefully with the view to taking action to remedy the evil.

THROUGH the trustees of the late Mr. James Holden, of Marsland, near Rochdale, the Delamere Forest Sanatorium for Consumption has received a grant of £10,000. One of the conditions being that six beds shall be set apart for the use of Rochdale patients.

THE honorary secretaries of King Edward's Hospital Fund for London have received at the Bank of England the sum of £5,000 from the executors of Mr. Thomas John Bell.

AN initial meeting of the council of the Liverpool Institute of Tropical Research was held on August

2nd, when Sir Alfred Jones, K.C.M.G., was unanimously elected chairman; Viscount Montmorres being appointed director, and Mr. Eric Drabell the economic botanist of the Institute.

LIEUT.-COLONEL F. G. ADYE-CURRAN, M.D., F.R.C.S.I., has been elected representative of the Apothecaries' Hall, Ireland, on the General Medical Council for the ensuing year.

ON leaving the parish of St. Germans, where he had practised for the past forty years, a handsome testimonial was presented to Dr. J. B. Kerswill by the Earl of St. Germans on behalf of an influential local committee.

THE Council of the University of Leeds has received an intimation from Professor Edward Ward that, in consequence of the pressure of other matters, he feels constrained to relinquish the Chair of Surgery which he has occupied for six years. To the vacancy thus created Mr. Harry Littlewood, M.S. Leeds, F.R.C.S. Eng., has been appointed.

DR. D. J. THOMAS, medical officer to the Merthyr District Council during the past four years, has been appointed medical officer of Acton, and will begin his new duties at the end of September. His brother, Dr. D. C. L. Thomas, is medical officer for Stepney.

Special Correspondence.

[FROM OUR OWN CORRESPONDENT.]
BELFAST.

ALLEGED BOYCOTT OF A MEDICAL OFFICER.—The perennial question of medical officers' holidays came up at a meeting of the Lurgan Guardians last week, and the dispensary officer, whose holiday was in question, Dr. Reid, of Derrvadd, near Lurgan, wrote that he could not get a *locum tenens* at three guineas a week, the sum allowed by the guardians, and further alleged that he was being boycotted by his medical brethren in the district because he refused to sign a resolution the contents of which he had never seen. He said that Dr. Pedlow, of Lurgan, had arranged to act as his *locum tenens*, but had backed out of the agreement, and now no other local man would take the work. After much discussion the guardians declared themselves powerless in the matter; they would pay three guineas a week to any properly qualified person whom Dr. Reid could get to act for him, but unless he could get someone he could not have his month's holiday. Metaphorically speaking, they cursed Dr. Pedlow with bell, book and candle, but as he is not in their service he is not likely to be a whit the worse.

SMILEY COTTAGE HOSPITAL, LARNE.—The second annual meeting of the trustees and committee of this Institution was held last week, when a satisfactory report was presented. The patients treated during the year numbered fifty-four—thirty medical and twenty-four surgical, and fifteen operations were performed. There is so much Scotch blood in the Larne district that the people are somewhat more cautious than usual, and slow to take up any new idea, but they are beginning to realise the value of Sir Hugh Smiley's generous gift to their town, and no doubt the hospital, which is a model one in every respect, will soon be much more freely utilised.

By August 11th sixty-eight fresh cases of yellow fever had occurred at New Orleans, and five more deaths were announced.

THE Board of Management of the Queen's Jubilee Hospital has received £1,000, from the trustees of the late Mr. G. F. Platt. Substantial amounts have recently accrued to the funds of this charity from various quarters, in addition to a handsome grant from the Hospital Sunday Fund.

Special Articles.

THE HOUSE OF LORDS AND PROFESSIONAL SECRECY.

McEWAN v. SIR PATRICK HERON WATSON.

THAT thorny question, the legal relations of professional secrecy, does not seem to be made plainer by the decision of the House of Lords in the action for slander which has for some time been proceeding against Sir Patrick Heron Watson, references to which have from time to time appeared in *THE MEDICAL PRESS AND CIRCULAR*. The litigation arose out of an action for separation on the ground of cruelty brought by Mrs. McEwan against her husband, as a preliminary to which she was in October 1901, at the instance of her law agents, examined by Sir Patrick Watson. His opinion, however, was unfavourable to her case, and he was not cited as a witness on her behalf. Two years after his first examination, on the eve of the trial of the action for separation, Sir Patrick again saw Mrs. McEwan, this time at the request of her husband's solicitors, and was called as a witness for the defence. In the course of his evidence he disclosed the facts learned and the opinion formed at his first examination, and one of these formed the alleged slander—viz., that the pursuer, being *enceinte*, and having left her husband's for her parents' residence, was desirous of terminating her pregnancy with the object of freeing herself from any reminder of her marriage. The action for separation failed, and in the sequel Mrs. McEwan and her father sued Sir Patrick Heron Watson for damages alleged to have resulted from his revelation in precognition and in the witness-box of information obtained while acting as her confidential agent and adviser. The defence was that the privilege of a witness was absolute as regards his utterances in court, and that similar protection extended to the precognition, as the written statement which a witness gives to a solicitor, and on which his evidence is based, is called in Scotland. The Court of Session decided that no action could lie as regards evidence, but allowed issues on the question whether the statements made as precognition were slanderous. Against this judgment Sir Patrick Heron Watson appealed, and the House of Lords reversed the decision of the Court below. The case for the appellant was that to limit the privilege of a witness to his evidence in open court, and to deny it to his preliminary statements made to solicitors and counsel, would be to render the protection illusory, since witnesses would decline to make statements to agents which might be actionable, while solicitors would hesitate to produce witnesses in ignorance of the precise evidence they were prepared to give. Mr. Haldane, for the defence, admitted that it was no part of his case to contend that statements made in the witness-box were actionable, nor even the taking of precognitions, but argued that a skilled witness was not entitled to impart the information acquired in his professional capacity to others than the parties who employed him. The Lord Chancellor gave his decision in favour of the appellant on the broad ground that the immunity of a witness in a law court was complete, and that not to extend the same immunity to statements made in precognition would hamper the administration of justice. That the decision of the House of Lords has been hailed with relief by the legal

profession in Scotland may well be imagined, for the lot of a solicitor getting up a case, and met by a refusal of witnesses to give information which might prove actionable, would be none too happy; the esteemed President of the College of Surgeons may also be congratulated on being at last freed from the harassing worry of a long-drawn-out litigation. But the question of the professional secret seems more involved than ever. The Lord Chancellor in his judgment dismissed the matter as not arising in the condescendances, and we have only his conversation with Mr. Haldane to guide us as to his views. If A employs B to give his professional opinion with a view to legal proceedings, and if that opinion is against A's case, is B entitled to accept employment from A's opponent, and to divulge to him information obtained in his previous employment by A? The answer would seem obviously in the negative, yet the matter is less simple than appears at first sight. As the Lord Chancellor said, one side cannot appropriate a witness, while to Counsel's proposition that the information acquired by Sir Patrick Watson belonged to his client, and that he was not at liberty to disclose it to the other side, Lord Halsbury replied that after fifty-five years' experience he had never heard such a privilege claimed before. Mr. Haldane's contention was that under the circumstances it was Sir Patrick Watson's duty to decline to give the information either in the witness-box or precognition—and with this view many medical men would at first blush agree. But the crucial point in the matter is this: During Sir Patrick's evidence, in which he disclosed facts learned during confidential employment by Mrs. McEwan, no objection was raised on her behalf by her counsel, and by this acquiescence at the time they must be held to have deprived themselves of the right subsequently to dispute the propriety of utterances which were allowed to pass unprotested, and without any attempt to suppress them. It may freely be admitted that the position is not a very satisfactory one; fortunately it is not likely to recur, and the lesson to be drawn from it seems to be that a medical man who has acted as an expert adviser for a litigant, should decline under any circumstances, whether his opinion be favourable or not, to accept employment from the opposite party.

Correspondence.

GERMANY AND FRANCE.—THE PHYSIOLOGICAL BASIS OF NATIONAL STABILITY.
To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—In a recent leading article a prominent daily paper touched, although only casually, upon the dominant factor in the present relations between France and Germany. The following is the passage:—"Though the French army of to-day is far different from what it was then [in 1870], there is still a great disproportion between the resources of France and Germany. Germany, with a much larger population, can place a far stronger force in the field." The uneasiness of France in her present situation is dwelt upon by many public writers; but none of them discuss its prime cause. The uneasiness of France is due to the fact that since 1871 the population has remained stationary—about 38,000,000. This number is only kept up by immigration of Italians, Swiss, and Germans. France, with the most fertile soil—a soil capable of maintaining many more millions than at present subsist upon it—the most magnificent climate,

and the most intelligent populace of Europe, has not enough men for her home requirements. She cannot spare, and virtually does not send, any emigrants to occupy and develop the vast possessions, misnamed colonies, which she has acquired mostly within late years; so that, on the whole, these have proved a useless burden upon, and source of weakness to, the State. It cannot be doubted that these territories will in time, either by peaceful or warlike conquest, be overrun by stronger and more prolific races. They may be even now the chief object of German covetousness. The population of Germany, which at the present rate of increase—the most rapid among the peoples of Western Europe—doubles itself in fifty years, stands now at upwards of 60,000,000; and the disparity between the two peoples will, of course, soon be much greater.

The causes of the stagnation of population in France are by no means hidden. They are understood not only by her men of science, but by every intelligent citizen. Children are few because parents are skilled in the art of preventing conception, and deliberately practise it. The dislike of a numerous progeny has its origin in the spirit of narrow anti-social egoism which has gradually grown until it permeates the great bulk of the race. Every higher aspiration is subordinated to the desire for a life of ease. Toil and self-sacrifice are regarded merely as the sources of pain and unhappiness. The number of children in families is governed by the fortune of the parents, but they very rarely indeed exceed three or four. Every girl has to be provided with a *dot* sufficient to attract a husband; every boy has to have an income assured, so that with a business to inherit, or a Government post gained, he may be safeguarded against the chance of poverty. The result is, that for every girl of the well-to-do class, unless she be a hopeless cripple in body or mind, a husband is found; for every man of the same class a wife—when not preferring mistresses—if he desire one. The stimulus to strive which comes from being thrown upon his own resources is very largely lacking to a Frenchman. He stays at home where the parents find an easy career for him; and he is too often brought up in a way that produces a want of the manly qualities which can be developed, as a rule, only in those who have to fight their own way in life. Besides thus restricting population, the French have been, for many years, carrying on what is, in fact, a gigantic system of artificial selection, ensuring to a large extent the survival of the least instead of the most fit. They are committing what has been styled "automatic race suicide." They are going to destruction owing to the same vices of civilisation that destroyed many nations of antiquity, but with the difference that they are going not blindly, but with eyes wide open and with a full view of the inevitable end. The main forces of evolution are as active to-day as in the old times, when the barbarian came down on decadent Rome. Dying nations will be replaced by the more virile, and the more quickly the more closely in contact they lie. In the case of France and Germany history is repeating itself. No prophet was needed to foretell what is now happening; it must have long been anticipated by serious students of contemporary history. Finally, let us bear in mind that we in these islands dare not look with pharisaical eyes upon the faults of our neighbours. We are following their example. Not only at home, but in the colonies, notably Australia, the birth-rate is declining, and there is no doubt about the cause. If this decline continues for a few years we shall be in a position similar to France. The expansion of the Empire will certainly be checked, and the first long step in its decline will have been made. As the weakness of France, rather than the strength of Germany, constitutes the danger near home, so the decadence of the Anglo-Saxon rather than the advance of the yellow races constitutes the peril to the wider world.

I am, Sir, yours truly,

HENRY SEWILL.

P.S.—A long despatch from Berlin appeared

in the *Times* of July 13th, in which the able correspondent of that paper discusses the situation, the following significant passage occurs:—"With the cynicism and callousness which characterises German methods of dealing with concrete or abstract political problems, it is already being calculated upon the statistical basis of census returns that in process of time France will be outnumbered in point of population by Germany to such an extent that she will be compelled to abdicate her position as a colonial power in favour of her hungry and more prolific neighbour."

DR. WALSH'S CAP-FILM METHOD OF TREATING RINGWORMS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—As a general practitioner I am truly grateful to hear of any method whereby ringworm of the scalp can be isolated and treated at the same time. Ringworm is common in the lower middle classes, and I can testify that I have found such cases a perfect bugbear. Treatment is carried out faithfully at first, but after a time the friends grow careless, and the case drags on month after month, or year after year in spite of every effort on the part of the medical attendant. Dr. Walsh's method of scalp isolation is simplicity itself, and if it cures as well as isolates, it will indeed be a god-send to yours truly,

A GENERAL PRACTITIONER.

Dulwich, August 10th, 1905.

STRAPPING THE CHEST IN TUBERCULOUS DISEASE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Some thirty years ago, Dr. McCree, of Belfast, published an article in THE MEDICAL PRESS AND CIRCULAR about strapping the chest in tuberculous disease when confined to the upper lobes of the lung. I several times have found great benefit from it. I lately had two cases of disease of the right lung in females. Both of them were spitting some 12 ozs. or more daily; one had also night sweats, and at the time seemed almost a hopeless case. The case, though it was last March and the weather was cold and damp, rapidly improved; she is now almost well, and expectorates very little at all.

The other case improved very much, and the expectoration diminished to one-fourth. Unfortunately she has Bright's disease very far advanced, so her case is hopeless.

The plaster must be carried over the shoulders, well down back and front, and cross-straps under the armpits and sides of chest. This must be done carefully, so as to practically close the chest and chest movements as much as possible. Unless done every fourteen or twenty-one days they are useless, as they get loose and troublesome. Both patients sent me word to do it again when loose, as they said it gave them great relief. I also advised them to use the arm of the side affected as little as possible.

My excuse for troubling you with this communication is that any remedy that helps towards a cure should not be neglected, and I know from personal experience that constant coughing up matter is one of the things that wear out a patient.

I am, Sir, yours truly,

CHARLES B. STONEY, M.B., M.Ch.

Diss, August 9th, 1905.

THE International Congress of Anatomy has arranged a meeting at Boston in 1907.

Poison given for Medicine.

THE death under distressing circumstances is reported of the little daughter of Mr. Oliver, head gardener to Sir Mountstuart Grant Duff, of Lexden Park, Essex. The child had suffered from whooping-cough, and her mother, on being suddenly roused from sleep, by a mistake gave the child a poisonous lotion intended only for outward application.

Obituary.

CHRISTOPHER HEATH, F.R.C.S.ENG., LL.D. MONT.

THE death of this gentleman, which occurred suddenly last week at his residence in Cavendish Square, London, will be viewed generally as a great professional loss. Few names are better or more widely known in the ranks of brilliant surgeons than that of Christopher Heath, who was Emeritus Professor of Clinical Surgery in University College, London; Consulting Surgeon to University College Hospital, and a former President; Hunterian Orator, Bradshaw Lecturer, and Examiner of the Royal College of Surgeons of England. He was born in 1835, being the son of Mr. Christopher Heath, of Gordon Square, and grandson of Mr. John Heath, R.N., who served in Lord Howe's flagship more than a century ago. Mr. Heath was educated at King's College School, and in his early days at King's College Hospital he was much associated with Sir William Ferguson; he was for a few years assistant surgeon and lecturer on anatomy at Westminster Hospital, where he wrote his "Practical Anatomy," which ran through eight editions. In 1866, he was appointed assistant surgeon to University College Hospital. In 1867 he was awarded the Jacksonian Prize of the Royal College of Surgeons for his essay on "Injuries and Diseases of the Jaws," which became the standard work on that subject in the English language. His "Course of Operative Surgery" gives a concise exposition of the operations performed under his direction as teacher of operative surgery. In 1871 he became surgeon to the hospital, and on Sir John Erichsen's retirement in 1875 Holme Professor of Clinical Surgery. The conciseness and clearness with which he lectured is well illustrated by his "Clinical Lectures on Surgical Subjects." He devoted himself to the task of impressing upon students the important features of common surgical affections and of ascertaining by question and answer that each student grasped these essential features. Mr. Heath's manual of "Minor Surgery" has passed through no fewer than twelve editions. His "Dictionary of Practical Surgery" and his "Students' Guide to Surgical Diagnosis" are both well-known works. At the Royal College of Surgeons, Mr. Heath filled all the important positions. In 1875 he became a member of the Board of Examiners in Anatomy and Physiology, in 1883 a member of the Court of Examiners in Surgery. He had already in 1881 been elected a member of the council of the college, and in 1895 he became president. In 1897, Mr. Heath was invited to deliver the second course of Lane Medical Lectures in connection with the Cooper Medical College in San Francisco, and the University of Montreal seized the opportunity of his presence on the American Continent to confer upon him the degree of LL.D. He leaves a widow and five sons and one daughter. In Mr. Christopher Heath the medical profession has lost a distinguished ornament. Not only was he a bold and brilliant operator, but he had the great gift of teaching. No great surgeon of his generation had a finer record as a teacher, and his fame in that direction attracted many students to University College.

JOHN WILLIAM OGLE, M.A., M.D., F.R.C.P.

LAST week an old and much esteemed practitioner, Dr. John William Ogle, Consulting Physician to the St. George's Hospital, died at the Vicarage, Highgate, at the age of 81. He graduated M.D. in 1857 and F.R.C.P. in 1855, and was Vice-President of the Royal Med. Chir. Soc. in 1885. Dr. Ogle had a long connection as lecturer and examiner at St. George's Hospital, and contributed many valuable articles to the leading medical journals. By his death we lose one of the best-known men, who united wide culture to the knowledge more immediately connected with his profession.

Literature.

THE INFLUENCE OF GROWTH ON CONGENITAL AND ACQUIRED DEFORMITIES. (a)

THIS book from the pen of an American writer is very much like many which have preceded it on the same subject.

The author states in his introduction that he ventures to present to the reader a new volume on orthopædic subjects, not because there is any lack of excellent systems and text-books, but rather to emphasise what seems to him to be at the base of practice in this specialty, the fact that prevention and cure are to be found in so managing a case and equipping a patient that natural growth will be the principal factor in recovery. He then goes on to quote Hilton's remark that repair is but the repetition of growth. The same elements, the same kindred conditions, are necessary to the same results.

The treatise is divided into ten chapters, which include the subjects of Club Foot, Deformities caused by Infantile Paralysis, Tubercular Joint Disease, Hip Disease, Angular and Lateral Curvature of the Spine. There is nothing very new in the book, but like many others of the same kind it is plain, practical, and readable.

A SYSTEM OF CLINICAL MEDICINE. (b)

IT is obvious that in writing on clinical medicine the author ought to approach the subject of disease as it presents itself to us at the bedside. Inquiry elicits certain signs and symptoms and we have to decide this probable cause. To do this we must pass in review all the possible causes, and we must have before us a mental table of the morbid conditions of which the actual symptoms may be the manifestations. It is the merit of the author of the System to have realised the importance of this method of imparting a knowledge of disease and to have applied it *seriatim*. The method is even more essential to students than to practitioners, inasmuch as it trains them how to reason on the basis of their own observations. It is indeed the method adopted by all the great clinical teachers of modern times, whose principles the author has embodied in these 1,100 pages of text—viz., to proceed from symptoms and signs to diagnosis, prognosis, and treatment.

The student preparing for examination will find this work specially useful in that it provides him with exactly the kind of information for which examiners yearn. Suppose he is shown a case in which albumin is present in the urine, obviously he will be asked what is the probable cause of the leakage. We turn to "Albuminuria," and we find a schedule of the morbid conditions that have this symptom in common, and incidentally it is explained how we are to differentiate between them. This is precisely what the ordinary text-book on medicine fails to do.

The method is equally useful in respect of treatment, for after all, treatment is mainly symptomatic only that the particular symptom has to be dealt with somewhat differently according to its probable cause. Here again, in ordinary text-books, the student is taught how to treat disease, as if a disease were an entity, instead of, as it is, a concatenation of symptoms.

Yet another advantage accrues, as the author points out, to the young observer from this process of balancing evidence and comparing diseases. It not only impresses facts upon the memory, but it constitutes one of the best possible means of training him to habits of accurate and complete observation, and of systematic and productive thought; his faculty of systematising

(a) "The Influence of Growth on Congenital and Acquired Deformities." By Adoniram Brown Judson, A.M., M.D., Orthopædic Surgeon to the Out-Patient Department, New York Hospital. Illustrations 134, pp. 276. New York: William Wood and Co., 1905.
(b) "A System of Clinical Medicine." By Thomas D. Savill, M.D., London, Physician to the West-end Hospital for Diseases of the Nervous System, and St. John's Hospital for Diseases of the Skin, &c. In two volumes. London: J. and A. Churchill. Price, 12s. 6d. net.

his knowledge is gradually increased and his reasoning powers strengthened and corrected. He finds that without accuracy in respect of the most minute details he may be led astray by the more important ones, that without system in the marshalling of his facts, he will not be able to apportion the proper significance and importance of each, thus incurring the risk of arriving at erroneous conclusions, based though they may be on correct premises and facts.

Although we have insisted more particularly on the value of a work of this kind for students, it is hardly necessary to state that the non-application of this closely reasoned method is at the root of most of the errors imputed to general practitioners. Busy practice creates a tendency to deal with symptoms at first hand, without stopping to inquire of what they are symptomatic. If the practitioner jumps too hastily at a diagnosis of tonsillitis, for example, he will certainly overlook cases of diphtheria, syphilis, and even scarlet fever, and this remark applies to all leading symptoms.

The work is provided with illustrations and diagrams where necessary to the elucidation of the text, and there are useful dietetic tables and therapeutical formulæ. The author is to be congratulated on having satisfactorily accomplished his self-imposed task and no doubt, in future editions, he will still further elaborate the method in regard to details.

DISEASES OF THE STOMACH AND INTESTINES.

It is a pleasure to be able to give praise to the literary work of an American colleague, and to Dr. Boardman Reed's "Lectures on Diseases of the Stomach and Intestines" (a) we can do so unreservedly. There are but two books on this side of the Atlantic with which it can be compared for knowledge of subject, completeness and lucidity, and besides these books it takes its stand as an authoritative exposition of all that is well founded, durable, and trustworthy in modern methods and modern science, in connection with diseases of the gastro-intestinal tract. If we have a criticism to offer it is that the lectures on the stomach are fuller and more exhaustive than those of the lower part of the alimentary tract, but we presume that this is so because Dr. Reed is brought into more frequent personal contact with sufferers from gastric troubles than with those whose maladies are situated in the intestines. We make this presumption because personal experience is the key-note of the volume. Scissors and paste are conspicuous by their absence, though due recognition is given to the work of others in their appropriate spheres. As we read we feel we are walking side by side with a practical physician who is a physician first, a scientist next, and a student most of all. Then, Dr. Boardman Reed has been happy in the choice of lecture-form in which to present his knowledge to us. Though never undignified, he is affable, easy, charming, he knows exactly where our difficulties lie, he knows how to anticipate and circumvent them. He tells us how, in simple, colloquial, straightforward style. There is no assumption of superiority; all are learners, and he is merely telling us how he learned; nothing is taken for granted. If we want to coax a stomach-tube down a refractory patient's gullet, he relates his own method of doing so; if we forget where McBurney's point is, he mentions it as a necessary detail; if we are unacquainted with the method of applying intra-gastric faradism, he shows how it is done. Full of information to the general physician or "specialist," the book is essentially one for the general practitioner, who can but feel grateful to the author for having coached him so carefully through all the complications that beset the present study of gastric disorders. But though devoting himself to a special study, Dr. Reed never forgets that he is a physician. In Lecture XXII., which he gives as a preliminary to description of the various therapeutic procedures

(a) "Lectures on Diseases of the Stomach and Intestines, for Practitioners and Students." By Boardman Reed, M.D., Professor of Diseases of the Gastro-Intestinal Tract, Temple College, Philadelphia. Bristol: J. Wright and Co., 1905. 21s. net.

that may be undertaken in diseases of the stomach, he emphasises most strongly the dangers of reliance on this, that, or the other method. "Many failures in treatment," he writes, "occur in cases in which the physician has made a correct diagnosis, but places too little stress in his directions to the patient upon the importance of changing radically the faulty modes of living which produced the disease. Unless we stop the leak, however, which is draining away the energies of the patient, we shall make little permanent progress in curing him, whether we rely chiefly upon hydrotherapy, massage, or other manual treatments, electricity, vibratory stimulation, climatotherapy, or merely upon the most skilfully concocted combinations of medicine." This is the spirit in which a treatise on a particular part of the body should be animated—a well-balanced, well-proportioned conception of the patient as a sick man, not a mere *corpus vile* for the practice of special methods. In discussing treatment, Dr. Reed is as good as in describing methods of examination, and much is to be learned from his statements of facts that he has verified himself. For instance, in speaking of the use of alkalies in stomach affections, he contradicts emphatically the oft-repeated statement that alkalies before meals increase the secretion of HCl, whilst after meals they diminish it. Small doses of alkalies always increase, and large doses always diminish acidity. The failure to neutralise acidity often lies in the fact that 10 to 15 grains of bicarbonate are given instead of much larger doses. This Dr. Reed has often confirmed in practice. The whole book is full of accurate information, practical hints, and sound thinking.

CLEFT PALATE AND HARELIP. (a)

THE chief object of Mr. Edmund Owen's interesting little monograph is evidently, as he himself says, to bring into more general notice the excellent work which has been accomplished in the treatment of cleft palate by Dr. Tauman Brophy, the President of the Chicago College of Dental Surgery. Dr. Brophy's method in operating on the cleft palate in infants consists, after paring the edges of the cleft and passing silver sutures through the substance of the maxilla, in squeezing the maxilla together; this being facilitated by incising the mucous membrane over each malar process, and dividing the maxilla sufficiently to enable their palatine process to be thrust into the middle line. Although Mr. Owen says in his preface that he hopes young surgeons may find help in the pages of this little book in overcoming the difficulties of operations on cleft palate, the explanation of the operation by Dr. Brophy's method would not, we think, be of as much service to the neophyte as to the surgeon skilled in operations on the palate; but on the other hand the descriptions of the operation undertaken after infancy is very lucid, and the chapters on the preparation of the patient and on the care of the child after operation are very practical and instructive. The chapter on the operation for harelip is very interesting. In fact, the whole book teems with hints that should be of great value to every practical surgeon.

THE SEWAGE PROBLEM. (b)

THIS book is a brief digest of fourteen volumes containing the evidence and the accompanying reports by the officers of the Royal Commission on Sewage Disposal, in which the compiler deals with the more important evidence on some of the practical points. He has also drawn "to a limited extent upon outside sources for information which seemed to throw light on the matters under consideration." The writer has

(a) "Cleft Palate and Harelip." (Medical Monograph Series.) By Edmund Owen, M.B., F.R.C.S. Pp. 103. London: Baillière, Tindall and Cox.

(b) "A Review of the Evidence Collected by the Royal Commission on Sewage Disposal." By Arthur J. Martin, Assoc. M.Inst.C.E., M.R.San.I. Price 8s. 6d. net. 1905. Pp. 363-xvi. London: The Sanitary Publishing Company, Ltd.

endeavoured "to indicate the general trend of the Commissioners' investigations, and to bring together in a concise form, some of the evidence which they have collected with regard to certain practical questions, the information concerning which has hitherto been both scanty and disconnected."

To anyone who is likely to have occasion to refer to this subject, we heartily commend this volume, compiled as it is, by one who is capable of appreciating the relative values of the opinions of those gentlemen who had the honour of giving evidence before the Commission, and whose knowledge of the subject is so great as to allow him to judge with accuracy where it would be advisable to supplement the evidence, with information from other sources, and remarks on the subject based on his own experience. It would greatly benefit the scientific world if experts in other branches of science, would lay us under obligations similar to those Mr. Martin has imposed on us, with regard to other Royal Commissions. Such works edited by capable men, would be much more widely read and better appreciated than the bulky volumes issued under the auspices of his Majesty's Government.

NEW BOOKS AND EDITIONS.

The following have been received since the publication of our last list:—

THE ABERDEEN UNIVERSITY PRESS, LTD. (Aberdeen).
The Royal Medical and Chirurgical Society of London. Centenary 1805-1905. By Norman Moore, M.D., etc., and Stephen Paget, F.R.C.S. Pp. 337.

BAILLIÈRE, TINDALL AND COX (London).
The Diagnosis of the Diseases of Women. By Palmer Findlay, B.S., M.D. Second Edition. Revised and Enlarged. Illustrated. Pp. 588. Price 21s. net.

A Handbook of Intestinal Surgery. By Leonard A. Bidwell, F.R.C.S., Illustrated. Pp. 167. Price 6s. net.

Carcinoma of the Rectum. By F. Swinford Edwards, F.R.C.S. Pp. 47. Price 2s. 6d. net.

CASELL AND CO., LTD. (London).
The Care and Management of Delicate Children. By Dr. Percy Lewis. Pp. 192. Price 3s. 6d.

MESSRS. J. AND A. CHURCHILL (London).
On the Hours of Sleep at Public Schools. By T. D. Acland, M.A., M.D., etc. Pp. 33. Price 1s.

WM. GREEN AND SONS (Edinburgh).
A Contribution to the Pathology of the Endometrium. By Jessie M. Macgregor, L.R.C.P. & S., M.D. Illustrated. Pp. 52.

CHARLES GRIFFIN AND CO., LTD. (London).
An Introduction to Midwifery: A Handbook for Medical Students and Midwives. By Archibald Donald, M.A., M.D., etc. Sixth Edition. Illustrated. Pp. 192. Price 5s.

HOMŒOPATHIC PUBLISHING CO. (London).
Homœopathy Explained. By J. H. Clarke, M.D. Pp. 212. Price 2s. net.

H. K. LEWIS (London).
The Child's Diet. By J. Sadler Curgeaven, M.R.C.S., L.R.C.P. Pp. 96. Price 1s. 6d. net.

A Synopsis of the Principal Changes in the United States Pharmacopœia. By W. Harrison Martindale, Ph.D. Pp. 36. Price 2s.

YOUNG J. PENTLAND (Edinburgh).
The Edinburgh Medical Journal. New Series. Vol. XVII. Edited by G. A. Gibson, M.D., F.R.C.P., A. Thomson, M.D., F.R.C.S., and H. Littlejohn, M.B. Pp. 676.

THE SCIENTIFIC PRESS, LTD. (London).
A Practical Guide to Cookery in West Africa and the Tropics. By Sister Cockburn. Pp. 160. Price 3s. net.

W. B. SAUNDERS AND CO. (Philadelphia).
Dietetics for Nurses. By Julius Friedenwald, M.D., and John Rubrah, M.D.

A Text-Book on the Practice of Gynaecology. By W. Easterly Ashton, M.D., LL.D.

Atlas and Text-Book of Topographic and Applied Anatomy. By Prof. D. O. Schultz. Edited by G. D. Stewart, M.D.

Malarial Disease, Influenza and Dengue. By Dr. S. Mannaberg and Dr. O. Leichtenstem. Edited by Ronald Ross, F.R.C.S., etc., etc., J. W. W. Stevens, M.D., and Alfred Grunbaum, F.R.C.S.

The Vermiform Appendix and its Diseases. By Howard A. Kelly, M.D., and E. Hurdon, M.D.

Atlas and Epitome of Operative Ophthalmology. By Dr. O. Haab. Edited by G. B. de Schweinitz, M.D.

A. SIZOLE (London).
Electrical Methods in the Treatment of Affections of the Stomach and Intestines. By George Herschell, M.D. Pp. 108. Price 3s. 6d. net.

SPOTTISWOODE AND CO., LTD. (London).
Minutes of the General Medical Council and of its Various Committees from Jan. 1st, 1905, to May 27th, 1905. With seven Appendices. Vol. XLII. Pp. 294.

JOHN WRIGHT AND CO. (Bristol).
Natural Science in Hygiene. By J. R. Watson, M.A., M.D. Pp. 62. Price 1s. 6d.

Disorders of Metabolism and Nutrition. Vol. VI. Drink Restrictions. By Prof. Dr. Carl von Noorden and Dr. Hugo Salmon. Pp. 86. Price 3s. net.

Medical News.

Fatal Accident to a Medical Man.

WE regret to announce the death of Mr. John Auterson, a well-known medical practitioner residing at Cookstown, co. Tyrone. Mr. Auterson was paying a professional visit on the night of August 5th, when his horse shied at a reflected light, and backed over the edge of the road, which at this point is quite unprotected. In consequence, trap and occupier were precipitated into a bog some fifteen feet below. Fortunately the accident was seen by a neighbour, and Mr. Auterson was removed to a neighbouring house, where he was attended by his professional confreres. On the evening of the following day he was removed to his own house, but he never rallied, and died on August 7th, the following day. Mr. Auterson became qualified in 1868, and thirty years ago he settled in Cookstown, where he had built up a large practice. He was unmarried.

Tuberculosis Commission.

THE President of the Local Government Board has informed Mr. Reginald Lucas, M.P., that it is not possible to say at present when the final report of the Royal Commission on Tuberculosis will be issued, but that the Commission hope to make an interim report towards the end of the present year.

Memorial to Jenner.

IN connection with the indication by the London County Council of houses in London which have been the residences of distinguished individuals, a memorial tablet was erected last week on No. 14, Hertford Street, Park Lane, where Edward Jenner, the originator of vaccination, resided in 1803. It bears the following inscription: "Edward Jenner, 1749—1823, Originator of Vaccination, lived here."

The Dublin Horse Show.

WE have been informed that there is a rumour in London that, owing to an outbreak of epigastric lymphangitis in parts of Ireland, the Horse Show held annually by the Royal Dublin Society, and commonly known as the Great Irish Horse Show, is to be abandoned this year. There is, however, no truth in this rumour. The show will open on the date originally announced, August 22nd, and will be even larger than that of last year. There are 1,222 entries representing 1,156 horses; in 1904 there were 1,219 entries, representing 1,150 horses, this too, in spite of the fact that all entries from infected districts have necessarily been refused.

PASS LISTS.

The Triple Medical Qualification.

At the July sittings of the Scottish Conjoint Board of the Royal Colleges of Physicians and Surgeons of Edinburgh and Faculty of Physicians and Surgeons of Glasgow, held in Glasgow, the following candidates passed the respective examinations:—

First Examination (five years' course).—Robert H. Jones, Denis Cogan, Thomas S. Douglas, Jehangir C. Balsara, William G. H. Brooks, Robert S. Watt, Phiroza Malabari, Daniel Murphy.

Second Examination (five years' course).—Matthew H. Fleming, Walter Riddell, George L. Irwin, Alexander P. Dias, Abraham D. Woolf.

Second Examination (four years' course).—George M. Macleod.

Third Examination.—Hugh G. Anderson, James Logan, John Dawson, Andrew Baxter, Alexander Dick, John A. Smith, Kenneth J. Logan.

Final Examination (and admitted Licentiate of the three co-operating authorities).—William N. Walker, William W. Dempster, William P. Timmon, Whitfield de Witt Henty, Joseph Owens, John MacNamara, Lorris E. Borden, William N. Alexander, Herbert M'Master, Jehangir C. Balsara, Julius E. Streeter, John P. Newton, Jesudasan S. Lamsch, James Taylor, (with honours): Alexander Dick, John G. Heathcote.

Notices to Correspondents, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

A. H. (Newark).—You will find an article on the treatment of stiff and contracted joints by air pressure in the *Munchener Med. Wochenschrift* No. 17, 1905. Klapp and Iler claim that by means of the passive hyperemia induced during the operation, absorption of the inflammatory exudation is stimulated.

REVENUE FROM THE SALE OF PATENT MEDICINE STAMPS.

We fear it would need a very bold Chancellor of the Exchequer to do away with the abomination known as the "Patent Medicine Stamp," when it yields to the Public Revenue the astounding sum of £331,439, the amount realised for the twelve months ending March last. This is an increase of £8,000 on the previous year, and nearly £100,000 more than it was a decade ago, strong presumptive evidence, were such needed of the enormous extent to which self-medication has attained.

DR. D. (Stirling).—Recurrent temporary amblyopia is probably a vaso-motor affection. It may depend on malaria. In any case it would be well to seek the advice of an ophthalmic surgeon.

HOSPITAL.—The application of the microscope to the study of food and drugs can hardly be said to be of recent date, seeing it was seriously made by Dr. A. H. Hassall about the middle of the last century. His work in adulteration is classical and famous as well as monumental.

ANALYST (St. Ives).—The only method we know of detecting sawdust in bread is to spread out the flour in a thin layer and moisten it with a 0.2 p.c. aqueous solution of paraphenylenediamine. On adding acetic acid the woody fragments assume an orange red colour while bran particles are unaffected. There is believed to be a good deal of adulteration in bread even in the present days of cheap flour.

X-RAYS (Cork).—The Röntgen Society in celebrating their 10th anniversary in Nov. 1905 are asking members to send in specimens of early work. They would doubtless be glad to see the radiograms you mention.

Meetings of the Societies, Lectures, &c.

MONDAY, AUGUST 14th.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—5 p.m. Dr. Davis: Medical Cases.

TUESDAY, AUGUST 15th.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—5 p.m. Mr. Bidwell: Surgical Treatment of Ascites.

WEDNESDAY, AUGUST 16th.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—5 p.m. Mr. Dunn: Tobacco Amblyopia.

THURSDAY, AUGUST 17th.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—4 p.m. Mr. Edwards: Surgical Cases.

FRIDAY, AUGUST 14th.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—5 p.m. Common Symptoms of Throat, Nose, and Ear Diseases.

Vacancies.

Noble's Isle of Man Hospital and Dispensary, Douglas, Isle of Man.—Resident House Surgeon. Salary £90 a year, with board and washing. Applications to Richd. D. Gelling, Honorary Secretary, St. George's Chambers, Athol Street, Douglas, Isle of Man.

Royal South Hants and Southampton Hospital.—House Physician. Salary £100 per annum, with rooms, board, and washing. Applications to T. A. Fisher-Hall, Secretary.

Royal Victoria Hospital, Bournemouth.—A House Surgeon. Salary £100 per annum, with board and lodging. Applications to the Secretary.

Exeter City Asylum.—Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Applications to the Medical Superintendent, Digbys, Exeter.

Essex and Colchester General Hospital.—House Surgeon, Salary £100 per annum, with board, washing and residence in the Hospital. Applications to Alfred G. Buck, Secretary, The Hospital, Colchester.

Metropolitan Water Board.—Laboratory Assistants.—
A Senior Chemical Assistant. Salary £300 per annum.
A Senior Bacteriological Assistant. Salary £300 per annum.
A Junior Chemical Assistant. Salary £175 per annum.
A Junior Bacteriological Assistant. Salary £175 per annum.
Two Laboratory Assistants. Salary £75 each per annum.
Applications to A. E. Pilling, Clerk of the Board, Savoy Court, Strand, W.C.

Parish of Saint Leonard, Shoreditch.—Second Assistant Medical Officer.—Salary £100 per annum, with rations, washing, and fur-

nish apartments in the Infirmary. Applications to Robert Clay, Clerk to the Guardians, Clerk's Office, 23 Kingsland Road, N.E. Manchester Children's Hospital, Pendlebury, near Manchester.—Junior Resident Medical Officer. Salary £80 per annum, with board and lodging. Applications to the Secretary, the Hospital, Pendlebury.

Appointments.

BLUMFELD, J., M.D. Cantab., Honorary Anæsthetist to St. Mary's Hospital, Paddington, W.

BONNEY, VICTOR, M.S., M.D., B.Sc. Lond., F.R.C.S., M.R.C.P., Emdeu Research Scholar to the Cancer Investigation Department of the Middlesex Hospital.

BUSHNELL, F. G., M.D. Lond., Vice-president of the Devon and Cornwall Sanatorium for Consumptive Poor.

ECKERSLEY, EDWARD AUTHUR, M.B., C.M., Clinical Assistant to the Hospital for Diseases of the Skin, Blackfriars, S.E.

EVANS, THOMAS, M.D., Clinical Assistant to the Hospital for Diseases of the Skin, Blackfriars, S.E.

FIELDEN, E. M. B., M.S. Durh., Certifying Surgeon under the Factory and Workshop Act for the Bracknell District of the county of Berks.

GOLDIE, E. M., M.D. Edin., Visiting Surgeon to the Royal Merchant Seamen's Orphanage, Snaresbrook.

Births.

ALEXANDER.—At Stalbridge, Dorset, the wife of W. G. Alexander, M.B., C.M. Edin., of a daughter.

BENNETT.—On August 10th, the wife of William Fay Bennett, M.R.C.S., L.R.C.P., of Barrow, near Bury St. Edmunds, of a daughter.

FENWICK.—On August 10th, at 29 Harley Street, London, the wife of W. Soltau Fenwick, M.D., of a son.

SANKEY.—On August 7th, at 25 South Quay, Great Yarmouth, the wife of J. Ivor Sankey, M.R.C.S., L.R.C.P., of a daughter.

WILLIAMS.—On August 10th, at Abbotsfield, Slough, Bucks, the wife of Ralph Paul Williams, M.D. Lond., of a son.

Marriages.

GARSTANG—VON MOLLIN.—On August 9th, at the Parish Church, Steep, Petersfield, Thomas James Garstang, M.A., of Bedales School, second son of the late Walter Garstang, M.D., of Blackburn, to Lisa, only daughter of the late Alfred Eric von Mollin, of Helsingfors, Finland, and of Agnes von Mollin, Petersfield.

OPERATIONS—METROPOLITAN HOSPITALS.

WEDNESDAY.—St. Bartholomew's (1.30 p.m.), University College (2 p.m.), Royal Free (2 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. Thomas's (2 p.m.), London (2 p.m.), King's College (2 p.m.), St. George's (Ophthalmic, 1 p.m.), St. Mary's (2 p.m.), National Orthopedic (10 a.m.), St. Peter's (2 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), St. Ormond Street, 9.30 a.m., St. Northern Central (2.30 p.m.), Westminster (2 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), Cancer (2 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).

THURSDAY.—St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), University College (2 p.m.), Charing Cross (3 p.m.), St. George's (1 p.m.), London (2 p.m.), King's College (2 p.m.), Middlesex (1.30 p.m.), St. Mary's (2.30 p.m.), Soho Square (2 p.m.), North-West London (2 p.m.), Chelsea (2 p.m.), Great Northern Central (Gynecological, 2.30 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), St. Mark's (2 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).

FRIDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), Guy's (1.30 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. George's (1 p.m.), King's College (2 p.m.), St. Mary's (2 p.m.), Ophthalmic (10 a.m.), Cancer (2 p.m.), Chelsea (2 p.m.), Great Northern Central (2.30 p.m.), West London (2.30 p.m.), London Throat (9.30 a.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), City Orthopedic (2.30 p.m.), Soho Square (2 p.m.).

SATURDAY.—Royal Free (9 a.m.), London (2 p.m.), Middlesex (1.30 p.m.), St. Thomas's (2 p.m.), University College (9.15 a.m.), Charing Cross (2 p.m.), St. George's (1 p.m.), St. Mary's (10 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).

MONDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), St. George's (2 p.m.), St. Mary's (2.35 p.m.), Middlesex (1.30 p.m.), Westminster (2 p.m.), Chelsea (2 p.m.), Samaritan (Gynecological, by Physicians, 2 p.m.), Soho Square (2 p.m.), Royal Orthopedic (2 p.m.), City Orthopedic (4 p.m.), Great Northern Centre (2.30 p.m.), West London (2.30 p.m.), London Throat (9.30 a.m.), Royal Free (2 p.m.), Guy's (1.30 p.m.).

TUESDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), Guy's (1.30 p.m.), Middlesex (1.30 p.m.), Westminster (2 p.m.), West London (2.30 p.m.), University College (2 p.m.), St. George's (1 p.m.), St. Mary's (1 p.m.), St. Mark's (2.30 p.m.), Cancer (2 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), Royal Free (3 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), Soho Square (2 p.m.).

PRACTICE.—Wanted to Purchase a small practice, near Dublin. Sea-side preferred.—Reply to B. B. care of MEDICAL PRESS AND CIRCULAR, 16 Lincoln Place, Dublin.

OCULAR THERAPEUTICS. (a)

By SYDNEY STEPHENSON, M.B., F.R.C.S.E.

(Continued from Page 162.)

LECTURE III.

5.—MISCELLANEOUS REMEDIES.

Supra-renal Extract.—In 1896, Dr. Bates, of New York, familiarised surgeons with the effects of an extract of suprarenal capsule upon the eye by showing that a 1 per cent. solution acted simply and solely as a powerful vaso-constrictor. The observation was not taken up widely, mainly because the suprarenal was difficult to procure and not easy to keep in an active state. Still, the experiments that were made confirmed Dr. Bates' main assertions. Since then, as everybody knows, adrenaline chloride has been introduced by Dr. Takamine, and placed upon the market by Messrs. Parke, Davis, and Co., thus giving us a most convenient, cleanly, and active preparation of suprarenal body. More recently still, three substitutes, namely, "renoform," "hemisine," and "paranephrin," have been introduced as cheap and convenient substitutes for adrenaline. "Renoform" is a fluid extract of the active principle of the suprarenal bodies, manufactured by a Berlin firm of chemists. Goldschmidt (*Die Therapie der Gegenwart*, July, 1903) recommends it as an economical, active, and non-irritating substitute for adrenaline, which, truth to tell, is somewhat costly. "Hemisine," one of Messrs. Burroughs Wellcome and Co.'s preparations, is described as "a derivative of the suprarenal gland, and is put up in ophthalmic tabloids, each of which contains approximately 1-100th of a grain." One of these tiny tabloids dissolved in 10 minims of water forms a solution of 1 in 1,000. I can testify to the fact that "hemisine" is an active preparation. "Paranephrin," a new product of the Darmstadt firm of Merck, is a stable 1 : 1,000 solution of paranephrin in 0.6 per cent. solution of common salt. Polte (*Archiv für Augenheilkunde*, November, 1904) has made careful experimental trials of the product, the action of which is that of suprarenal extracts in general.

From what has been said it will be obvious that we are now in possession of several trustworthy suprarenal preparations, British and foreign.

When a physiologically active preparation of suprarenal gland is dropped into the conjunctival sac, the mucous membrane becomes markedly blanched in the course of a few moments. As regards its whiteness, the eye may be said almost to resemble an artificial eye in appearance. There is no action upon the pupil, the accommodation, or, indeed, upon any other structure or function of the eye. The anæmic condition lasts for about an hour, more or less. The knowledge of this property of adrenaline has spread beyond the members of the medical profession. It appears that

trichomatous immigrants seeking admission to the United States have endeavoured to turn the vaso-constrictor powers of adrenaline to good purposes in concealing their disease. They have found that all evidences of mild trachoma can be obliterated for about half an hour if adrenaline be dropped into the eyes. However, the inspectors have been equal to the occasion, and now make not one but several examinations of suspicious cases.

It was at first thought that the intense vaso-constrictor action of adrenaline might be turned to advantage in the treatment of superficial diseases of the eye, and many trials in that direction have been made. But as Dr. J. A. Menzies has well said (*Ophthalmoscope*, Vol. II., 1904, p. 500), "congestion is Nature's attempt to remove the cause of a conjunctivitis by a free flushing with blood and lymph. To use adrenaline in such a case, without at the same time attacking the disease, is to thwart Nature's attempt at cure without introducing an alternative attempt. . . . The use of adrenaline in such a case is, therefore, a confession of helpless ignorance." In short, accumulated experience now shows that the main use of adrenaline must be sought in directions other than the relief of actual disease. The agent, it is true, does exert a beneficial effect upon a conjunctival disease, rare in England, Spring catarrh, but common enough in some other countries. At the same time, in my experience, it is not a specific even in that disorder. In glaucoma, also, adrenaline is certainly not devoid of power. Grandclément (*La Clinique Ophtalmologique*, 1904) has insisted upon the fact that it is capable of curing glaucoma without operation, provided the disease has not lasted long enough to produce organic tissue changes, and, further, that the drug, combined with physostigmine, be used very frequently—say every half-hour for several days. The same author (*Die Ophthal. Klinik*, August 20th, 1904) has improved sight in a case of buphthalmos—that is, congenital glaucoma—by using the following collyrium: eserine, 0.50; adrenaline, 1 : 1,000, 3; distilled water to 10.0. At the same time, it must not be forgotten that Mr. A. F. MacCallan (*Trans. Ophthalmological Society*, Vol. XXIII., 1903) has reported five cases of glaucoma in which adrenaline caused an increase in tension, an observation more recently confirmed in two cases of glaucoma by Dr. A. Senn (*Woch. f. Therapie u. Hygiene des Auges*, 1905). The result is, however, very unusual, and it would be unfair, as MacCallan himself admits, to lay undue stress upon the fact.

For my own part, I have never seen anything but benefit result from the addition of adrenaline to physostigmine in the medicamentous treatment of chronic glaucoma. The prescription I usually give combines $\frac{1}{4}$ grain of the sulphate of physostigmine with 4 drachms of a 1 : 2,000 solution of adrenaline chloride, and, if pain be a prominent feature, as stated before, five grains or more of dionine are added to the liquid.

The fact should be mentioned that the reckless employment of adrenaline has been known to produce failure of sight and softness of the eyeball, the latter

(a) Lectures delivered June, 1905, at the Polytechnic London.

lasting, as in Grandclément's case, for several months (*Die Ophthal. Klinik*, August 20th, 1904).

There are three other uses to which adrenaline or its substitutes may be put—(1) to prevent hæmorrhage during operations upon the eye; (2) to assist in the absorption of other remedies; and (3) to aid in the diagnosis of certain diseased conditions of the eye.

(1) With respect to the first of these uses, the prescription may stand: cocaine hydrochloride, 2 per cent. dissolved in adrenaline hydrochloride, 1 : 2,000; a drop into the eye every two minutes for six or eight minutes before operation. Cohn (*Woch. f. Therapie u. Hygiene des Auges*, November 24th, 1904) has experimented with a new combination of cocaine and adrenaline, which goes under the name of "eusemin." It contains, in addition to the two alkaloids mentioned, chloretone and physiological salt solution. It is most useful as a local anæsthetic in eye operations, and may be injected beneath the skin or the conjunctiva. There can be no doubt that when operating for squint, adrenaline does render the parts more or less bloodless, and in that way simplifies the operation, an important point, more especially if my plan of lengthening instead of dividing the tendon be adopted. For iridectomy and cataract, however, the preliminary vaso-constriction may be followed by reactionary bleeding into the anterior chamber, as happened to me in four successive iridectomies. Since that experience I have used adrenaline less frequently as a hæmostatic than I did formerly.

(2) With respect to the second use of adrenaline, namely, of helping the absorption of other remedies, it is a fact that when the eyeball is markedly reddened, as in acute iritis, atropine will act better upon the pupil if combined with adrenaline than if employed alone. But, according to Dr. R. Mengelburg (*Woch. f. Therapie u. Hygiene des Auges*, No. 32, 1903) there is a danger in that very fact, since symptoms of atropine poisoning are apt to be set up. It is thought that the lumen of the lacrymal passages is widened by constriction of the vessels, so that the passage of atropine from the conjunctival sac into the nose and throat is thereby facilitated. Again, in using fluorescein for the staining of raw spots on the cornea, the preliminary drop of cocaine or of adrenaline will render the process of colouration quicker and more complete. In the passage of a lacrymal probe, too, adrenaline by acting as an astringent to the mucous membrane, is often of service.

(3) As to the third point, by applying adrenaline to an inflamed eye, the distinction between conjunctival and ciliary redness may often be established in a very conclusive and pretty way, since the conjunctival system is alone affected by a single drop of the medication.

Jequiritol.—This agent, introduced by Römer, of Würzburg, represents, as Dr. Albert B. Hale (*loco citato*) has well said "the application of the modern laboratory idea to botanic as well as to therapeutic science." *Jequiritol* is a standardised abrin preparation obtained from the seeds of the *Abrus precatorius*, and intended to be a scientific and exact substitute for the older jequirity solutions, which in their turn replaced the ancient inoculation of an eye with gonorrhœal pus. It is supplied in four different strengths, with a curative serum and printed instructions for use in a wooden box by Merck, of Darmstadt. No. 1 concentration is the mildest, and No. 4 is the strongest. No. 1 kills a white mouse weighing 20 grm. within four days if $\frac{1}{2}$ grain be injected subcutaneously. Dropped into the eye in slowly increasing amounts and strengths, these liquids give rise to intense reaction, marked by redness, and swelling of the eyelids, chemosis, enlargement of the neighbouring glands, and so forth. When the symptoms appear likely to exceed the desired end, they may be mitigated by using the *jequiritol-serum*—that is to say, an antitoxin prepared upon the principle of Behring's serum.

Jequiritol is employed mainly for the clearing of corneal opacities, especially such as result from trachoma, eczema of the cornea, and interstitial kera-

titis. The agent does not appear to have been much used in this country or in America, although from other parts of the world conflicting reports as to its value continue to appear periodically. One school is represented by Dr. Henri Coppez (*La Clinique Ophthalmologique*, January 25th, 1903) who treated about 100 cases, and succeeded in healing ulcers, clearing pannus, and rendering the conjunctiva smooth. The other school is represented by Dr. Wecker (who introduced *jequirity*), who dwells upon the dangers and disadvantages of the new agent.

The preparation is expensive, and during its use patients must be confined to bed, or, at least, be made to keep the house. The pain and other discomfort caused by *jequirity* are serious drawbacks to anything like its general use. These and other considerations have led me to employ *jequiritol* in a sparing way and in selected cases only. I have careful notes of twelve such cases, and I will endeavour to summarise the results in ten of the cases as follows:—

The series included seven males and three females, whose ages ranged from six to fifteen years. In three both eyes were treated, and in seven one eye alone. The underlying condition which had caused the corneal opacities was trachoma in six instances and eczema in four. Reaction, as a rule, was insignificant until the strongest concentration of *jequiritol* was applied. Pain, membrane on the conjunctiva, chemosis, vascularity of the cornea, mastoid redness, swelling of the side of the face, enlargement and tenderness of the preauricular and cervical glands, and a rise in temperature to 100° F. or 101° F., were constant accompaniments of the cases in which *jequiritol* set up marked reaction. The complications of the treatment included abscess of the lacrymal sac—acute in one case, a child suffering from hereditary syphilis, and chronic in two others. In one patient, a girl, æt. 8, affected with active and vascular trachomatous pannus, seven applications of *jequiritol* led to severe reaction, associated with exfoliation of the anterior layers of the central region of the cornea. It became necessary in this case, the only one in the series, to make two applications of the "heils serum." With regard to the effects upon vision, there was no change for the better in four cases, and slight improvement in the remaining six cases. I am bound to say, however, that in no instance was the improvement in this respect greater than could be accounted for by the mere efflux of time, and was certainly not so pronounced as could have been obtained under simpler, more economical, and less painful methods of treatment.

In my hands, therefore, the results obtained from *jequiritol* treatment, although of some little scientific interest, are scarcely such as to justify me in undertaking further experiments.

X-RAYS.

During the last two years, X-rays, as well as currents of high intensity, have been widely employed in the treatment of diseases of the eye, sometimes with the best results. A timely note of warning, however, has been sounded by Dr. A. Birch-Hirschfeld (*V. Graefe's Archiv für Ophthalmologie*, II., October, 1904), with regard to the use of these powerful therapeutic agents in ophthalmic work. They may, indeed, unless used with proper precautions, cause most untoward complications, as, for example, loss of the eyebrows and eyelashes, inflammation of the conjunctiva, cornea, and iris, and in the deeper structures of the eye such changes as degeneration of the macular region and ganglionic layer of the retina and of the medullary fibres of the optic nerve. Birch-Hirschfeld, therefore, urges that the eyeball should be efficiently protected, and that exposure should neither be unduly strong nor repeated too frequently.

The list of diseases that have been treated with X-rays is already quite a long one, and includes (1) rodent ulcer and epithelioma of the eyelids, and sarcomata and other orbital growths; (2) trachoma; (3) tuberculosis of the conjunctiva; (4) spring catarrh; (5) blastomycetes; and (6) scleritis, superficial and deep.

(1) *Rodent Ulcer, &c.*—The cure of rodent ulcer and

epithelioma of the skin or the eyelids has now gone far beyond the experimental stage. In this connection, I will merely quote Dr. Sweet (*Medicine*, April, 1904) who has treated upwards of twenty such cases, with success in every instance except two. Sweet is of opinion that in our present state of knowledge it is no longer justifiable to resort to the excision of rodent ulcers and epitheliomata of the eyelids. With regard to sarcomata the position of X-rays is not so clear. However, an inoperable case of orbital sarcoma has been reported by Webster Fox (*Archives of Ophthalmology*, January, 1904) where restoration to the normal followed forty-six exposures to the focus-tube. Kienbock (*Woch. f. Therapie u. Hygiene des Auges*, February 25th, 1904) cured a sarcoma, which had produced bilateral exophthalmos and optic atrophy, by thirteen exposures spread over the course of three months. Bèclère (*Gazette des Hôpitaux*, June 14th, 1904) has also reported a successful case.

(2) *Trachoma*.—Trachoma has been treated with X-rays by Mayou, Walsh, Cassidy and Rayne, Bettremieux, Goldzieher, Pardo, and myself, with results that, upon the whole, compare most favourably with those obtained by the ordinary methods. Walsh and myself were the first to employ the high frequency current in this intractable disorder. The results were excellent, and cure was obtained, always without pain, and often in a surprisingly short time. It seemed to make little difference whether the current was applied directly to the diseased parts or merely transmitted to them through the closed eyelids. The tedium inseparable from holding the lids everted, as well as the exposure of the nurse's hands, may be avoided by employing the ingenious clip devised by Reid and Edmunds (*Lancet*, August 15th, 1903).

(3) *Tuberculosis of the Conjunctiva*.—I was the first to endeavour to cure this disease by means of X-rays. My patient, a girl, *æt.* 4, was cured in a month, without visible cicatrization of the conjunctiva, by thirteen exposures applied for ten minutes at a time, the tube being held six to ten inches away from the eye. In these somewhat rare cases I believe that X-rays will usually suffice without excision or scraping or cauterisation of the affected parts. Moreover, there is always a risk of exciting a generalised tuberculosis when we interfere surgically with these lesions, which as regards the conjunctiva are, in my experience, usually primary.

(4) *Spring Catarrh*.—Recovery of this curious affection by exposure to the emanations of the focus-tube have been reported by Starr, Bennett, and Allport. Allport (*Ophthalmic Record*, October, 1903) first removed the palpebral outgrowths, and then exposed the conjunctiva, everted by means of a lid-clamp, to the action of the X-rays. Cure followed eighty exposures.

(5) *Blastomycetes*.—The best cure for that singular disease, blastomycosis of the skin of the eyelids (instances of which have so far been met with almost exclusively in Chicago, U.S.A.), appears to be by the local application of X-rays, together with the administration internally of large doses of potassium iodide.

(6) *Scleritis, superficial and deep*.—Pardo (*Arch. di Ottalmologia*, January and February, 1905) has treated scleritis by the X-rays, and he claims that "these rays represent a real discovery, inasmuch as up to the present day there is no other direct therapeutic agent, but only means amounting to a purely symptomatic treatment."

RADIUM.

It would indeed be singular if that mysterious element radium, had not been pressed into service in the treatment of eye disease. As a matter of fact, it has been employed in (1) epithelioma, rodent ulcer, and naevi of the eyelids; (2) trachoma; (3) relapsing inflammation of the uveal tract; and (4) various painful diseases of the eye and surrounding parts.

The method adopted has been simply to place a few mg. of radium bromide of varying degrees of uranium activity (U) in a sealed glass tube, and to apply the little apparatus close to or over the eyelids for a given time. Two points seem to stand out clearly—first, that radium is simpler to apply than the X-rays, and,

secondly, that it may be used with comparative impunity about the eye. At the same time our knowledge of the therapeutic values of the α , β , and γ rays respectively may be said to be almost non-existent. The gamma-rays seem to be identical with the X-rays, and it is possible that the therapeutic results obtained from radium are more closely connected with them than with the other emanations, known and unknown, notwithstanding the fact that radium is estimated to give off a very small proportion only of these exceedingly penetrating rays.

(1) *Epithelioma, &c.*—With regard to rodent ulcer as it affects the skin of the eyelids, there can be no doubt whatever that radium is directly curative and that without pain, as witness successful cases reported in this country by J. Mackenzie Davidson (*British Medical Journal*, January 23, 1904), Sichel (*ibid.*), and A. S. Green (*Lancet*, March 19th, 1904). This method of treatment, although by no means always rapid in its results (as in a case of my own) has obvious advantages as compared with surgical measures. Naevi have been treated successfully with radium in several instances by Justus (*Woch. f. Therapie u. Hygiene des Auges*, June 22nd, 1905, p. 302).

(2) *Trachoma*.—Hermann Cohn (*Berliner Klin. Woch.*, No. 1, 1905) cured three cases of trachoma by means of a crystal of radium bromide, enclosed in a thin glass tube, the end of which was employed to touch each trachoma-body from ten to fifteen minutes daily. The observation has to some extent been confirmed and, indeed, even antedated in this country, although it may be noted that Mr. N. B. Harman (*The Conjunctiva in Health and Disease*, 1905, p. 196) obtained no improvement in two patients upon whom he experimented.

(3) *Inflammation of the Uveal Tract*.—Dr. Charles H. Williams (*Trans. American Ophthalmological Society*, vol. X., pt. ii., 1904, p. 269) obtained considerable improvement in a case of inflammation of the uveal tract by one minute applications of radium (1,500,000 U.), carried out for about four months two or three times a week with occasional intermissions. Williams also saw benefit follow the employment of radium in two other cases—ulcer of the cornea, and acute iritis with turbidity of the aqueous humour.

(4) *Painful Affections of the Eye*.—Dr. Darier (*Ophthalmoscope*, June and July, 1905) has made the important observation that the metalloid is capable of relieving pain when applied to the eyelids in such affections as rheumatic iritis, specific choroiditis, orbital neuralgia, and so forth. This result, in Darier's hands, now and then came about from a single application of radium of 240 U. for one or two hours. Besson, in his book upon "Radium and Radioactivity," (reviewed in *Centralbl. f. praktische Augenheilkunde*, June, 1905, p. 177) confirms Darier's observations so far as regards the pain of rheumatic iritis, traumatic irido-cyclitis, and epibulbar carcinoma.

(To be continued.)

MEDICAL ASPECTS

OF THE

WAR IN THE EAST:

THE JAPANESE RED CROSS SOCIETY AND ASSOCIATIONS FOR MEDICAL RELIEF.

By GEO. M. FOY, M.D., F.R.C.S.I.,
Surgeon to the Whitworth Hospital, Drumcondra.

THE kindness of a correspondent in Tokyo, who sent me an English translation of Wasuke Jikemura's report to the Japanese Government enables me to place this interesting historical sketch before the readers of THE MEDICAL PRESS AND CIRCULAR.

The Hakuaisha, which means the Philanthropic Association, was organised in the tenth year of Meiji (1877) during the Civil War in Kagoshima, and was the actual progenitor of the present Japanese Red Cross Society. During the war, which lasted six months, Count Tsunstami, a Member of the Council, and Viscount Yuzwui, conceived the scheme of sending

relief to the sick and wounded in the war. They succeeded in enlisting the services of two kindred spirits, who were members of the Senate, Josho Matsudaira, and Tadaski Sakurai, and so the Hakuaisa was inaugurated.

The promoters of the Hakuaisa then approached the Headquarters Staff of the Army sent to put down the rebellion, and on May 1st, 1877, received formal permission to commence operations, which they did at once, tendering their services to the Imperialists and Fudalists alike.

On the termination of the war in the September following, it was decided that the Hakuaisa should be made permanent, and that during times of peace they should work to remedy the defects which the six months' service had made apparent.

In 1886, when the Japanese Government gave its adherence to the Geneva Convention, the members of the Hakuaisa revised their constitution and by-laws in such a way as to allow of their affiliation to the Red Cross Society. The Society was now placed under the patronage of their Majesties and its name was changed to the Red Cross Society of Japan. In the following year the society received official recognition, and the revised rules were published with the Imperial sanction. The society celebrated its twenty-fifth anniversary in December, 1902, on which occasion more than 100,000 members assembled in Tokyo.

Her Majesty had always made it a point to be present at the general meetings of the society, a patronage and support which did much to ensure the success of the Association. For many years past the Imperial family contributed £1,000 a year for the hospital, and £500 a year for the patients, out of personal funds, besides making generous contributions from time to time.

The business of the society is in the hands of ten managers, chosen from the Permanent Council. A President and two Vice-Presidents are chosen from the number of the managers, but their appointment must have the Imperial sanction.

The Permanent Council consists of thirty members, residing in Tokyo, who are elected by the society at its annual general meeting. Three inspectors are likewise elected at the same meeting. The following are the present officers of the Society:—General Director, H.I.H. Prince Kanin. President, Count Masayoshi Matsukata. Vice-Presidents, Baron Yoshikata Hanabusa, Baron Takeo Ozawa. The local branches follow the lines of the administration. There is a local branch in every prefecture and the Prefectural Governor is always *ex officio* chairman of the branch. The membership is of three kinds, honorary, special, and regular. Each class has its own badge, and special badges of honour are given to those who have rendered special services to the society. Membership badges are not given until the names of the new members have been reported to his Majesty; the conferring of badges of honour requires in every case the Imperial sanction. The badges may be worn on public occasions like decorations. In December, 1887, there were only about 2,100 members; at present the membership is about 895,000.

During the China-Japan war, 1,587 persons were employed by the society in the work of nursing and medical relief. These persons assisted the Military Sanitary Corps in their work, at home, in the Reserve military hospitals established at Hiroshima and nine other places, and abroad, at the various Etape and fixed field hospitals in Korea and China. They also served on board hospital ships and on transports in attending on wounded and invalid troops. The total number of patients cared for in Tokyo and elsewhere during the war, including those in the Etape hospitals in the island of Taiwan, during operations subsequently undertaken in that island for the suppression of insurrection, was 101,423. Of these, 1,484 were prisoners. The work of the Head Office during the same period was as follows:—(a) Sending, free of cost, many thousands of gifts and presents from all parts of the country to soldiers in the field; (b) entertaining

troops on their way to the front, and welcoming them on their return; (c) visiting patients in hospitals, both in Japan and on the field.

During the operations in North China in the summer of 1900, the society was represented by 491 persons engaged in the military hospital at Hiroshima, as well as at Taku, Tien-tsin, Tung-chow, Shan-hai-kwann, and elsewhere. Two vessels, the *Hakuai Maru* and *Kosai Maru*, were at the disposal of the society, and many patients were thus conveyed between Taku and Hiroshima. The total number of persons relieved was 11,348, including 245 Frenchmen and 4 Austrians.

The relief work of the society has not, however, been limited to the care of sufferers in war. Japan is a volcanic country, and as such is liable to natural catastrophes of a terrible kind, such as are almost unknown in countries more favourably situated. During the thirty years which have elapsed since the first organisation of the society, the country has been visited by two or three great earthquakes, and one tidal wave of appalling proportions, to say nothing of hurricanes, famines, pestilences, and fires. In all these calamities the Red Cross Society has always been ready whenever required to stretch forth a helping hand.

Before the outbreak of the war with China neither the staff of the society nor the stock of materials in hand were adequately prepared for the strain of a sudden emergency. The society, however, gathered experience as it worked, and by degrees evolved a methodical and sufficient organisation not alone at the Head Office, but also at the various branches throughout the country.

According to the latest reports, the society has on its books the following *personnel*:—Superintendent medical officers, 14; medical officers, 273; apothecaries, 45; nurses, 1,920; male nurses, 763; probationers, 457. All these are under the direct control of Baron Hashimoto, Surgeon-General and Chief Medical Officer of the Red Cross Hospital. The material resources of the society are reported as follows:—Hospital ships, 2; medical cases, 398; instruments, sets of, 1,774; stretchers, 496; patients' clothes and bedding, 52,438; nurses' clothes and bedding, 27,199; miscellaneous articles, 2,060.

THE SOCIETY'S HOSPITAL.

This important institution was first established in 1876, under the name of Hakuaisa Hospital, in Iidamachi, Tokyo. It changed its name with the society, and was removed to a piece of land belonging to the Crown at Shibuya. The new hospital, which was much larger than its predecessor, was completed in May, 1891. Attached to the Hospital is a training school for nurses and medical attendants who are thus fitted for the special work of the society in times of war and catastrophe. In order to give the students opportunities of practical work, ordinary patients are received in time of peace, but it is an understood thing that in the event of war the hospital shall at once be placed at the disposal of the military authorities as a military reserve hospital. It was so used during the China-Japan War.

Red Cross Work at Chemulpo.—The care of the Russian seamen wounded in the action at Chemulpo was undertaken by the Special Japanese Committee of the Red Cross Society in Japan, aided by the Chemulpo Ladies' Relief Association. On February 13th and 14th, twenty-four Russian sailors were received into the English Church hospital at Chemulpo, kindly placed at the disposal of the Japanese authorities, and their comforts were well looked after, thanks very largely to the sympathetic assistance of the foreign community at the port.

The Russians were at first disposed to shrink from their Japanese doctors and nurses, but kindness soon broke down the barriers, and in a very few days after their arrival it was observed with pleasure that the convalescent patients were offering their aid to the nurses in the treatment of the others. The Chief Surgeon of the *Naniwa* was specially sent to the hospital by Rear-Admiral Uryu to inquire after the

wounded, and bear them the Admiral's message of sympathy, an act of courtesy which was much appreciated and duly acknowledged by the wounded seamen.

HOSPITAL SHIPS.

Immediately on the outbreak of hostilities, Japan notified to Russia that in accordance with the provisions of Articles I. and II. of the Geneva Convention, the following ships had been appointed as hospital ships for the relief of sick, wounded, and shipwrecked persons—to wit, the *Saikyo Maru* and *Kobe Maru*, chartered by the Japanese Government, and the *Hakuai Maru* and *Kosai Maru* belonging to the Red Cross Society.

SYMPATHY OF FOREIGN NATIONS.

On February 14th, 1904, the Japanese Minister at Berlin telegraphed to inform the President of the Red Cross Society of Japan that the German branch of the society was prepared to send nurses and surgical appliances and apparatus in case of need. On the same day the French branch of the society telegraphed their warm sympathy with Japan and offered to send a contribution of surgical material and a body of trained nurses, if required. The Red Cross Societies of Italy and Spain also offered contributions of material, aid, and appliances for ambulance work. The German Emperor telegraphed to the Empress of Japan placing the German Naval and Military Hospitals at Yokohama and Chingtao at the disposal of Japan. And an American lady proposed to come to the assistance of the Japanese Red Cross Society with a large number of trained nurses. To all these offers the Japanese Government, on behalf of the Red Cross Society, sent messages of gratitude accepting the offered contributions of appliances and apparatus, but declining the proffered services of the trained nurses.

ASSOCIATIONS FOR RELIEF-WORK.

Some of the many associations existing in Japan for the care of the sick and wounded in war, and the relief of the families of soldiers and sailors, in the field, which have lost their breadwinners, are the following:—

1. *The Association of Volunteer Nurses*, which was first organised in 1887, draws its members from the Imperial Princesses, the Court Circle, and the wives of the nobility and gentry, the present General Director and President being H.I.H. Princess Kanin, and the Marchioness Nabeshima. The members of the Association make it their duty to study nursing so as to be ready for practical service in time of war. During the China-Japan war the members of the association made bandages for the use of the Army and Navy Medical Departments, and served as nurses in the reserve hospitals in Tokyo and Hiroshima; and again, at the time of the operations in North China, they raised funds for presents to the sick and wounded, both Japanese and foreign, who were visited by their representatives in the hospitals at Hiroshima and other places. The Head Office of the Association is at the Red Cross Society's building in Tokyo; and there are thirty-two local branches in different parts of the country. The present membership of the Association is as follows:—Head office, 427; local branches, 4,200.

2. *The Ladies' Patriotic Association* draws its members from the same circles as the above, and has for its object to relieve the families of those who have died in action or during military service, and to care for those who are permanently disabled. The General Director of the Association is H.I.H. Princess Kanin, and the President, Princess Hisako Iwakura. The main office is in Tokyo, and there is a local branch in each prefecture. The Association has recently received the following contributions from members of the Imperial Family: H.I.M. the Emperor, £700; H.I.M. the Empress, £500; T.I.H. the Crown Prince and Crown Princess, £250.

3. *The Imperial Relief Association for Soldiers and Sailors* was established by nobles and prominent gentlemen in Tokyo with the same objects as the two above associations. The President is H.I.H. Prince Arisugawa, the Vice-Presidents, Counts Matsukata

and Inone. It is situated in Tokyo, and its originators during the early months of the war, contributed more than £100,000. The subscription list was headed by a donation of £10,000 from their Majesties; £1,000 from the Crown Prince; £500 from Prince Arisugawa, President of the Association; and £300 from the other Imperial princes.

4. *Volunteer Relief Work for the Marines*.—The wives of the Japanese naval officers also have combined to raise money and contribute articles, in order to give comfort for the naval officers and men in the campaign. The originators of this work are Mesdames Tomiko, Takagi, Shigeko Uryu, and Haruko Saito. The students of the Peeresses School, numbering about 426, under the command of their teachers, some 480 in all, every afternoon when school is over, employ their time in preparing bandages and so forth for the military hospitals.

NOTES ON CASES

OF

GONORRHOEA TREATED WITH ARGYROL.

By H. DE MERIC, M.R.C.S.,

Surgeon to In-patient French Hospital, London.

THERE is probably no disease which is followed by so many undesirable sequelæ or which presents so many difficulties with regard to treatment as that form of specific urethritis to which we apply the term gonorrhœa. There is certainly no disease in which patients show so much persistent wilfulness, such impatience of control and such disbelief in the remedies indicated by the surgeon, should they fail at once to produce a curative or at all events an ameliorating action. It is not too much to say that the keynote to successful practice is the ability to deal with a patient suffering from gonorrhœa, or still worse, a long-standing gleet. Nothing requires greater firmness, greater tact, and above all, so intimate a knowledge of details in modes of procedure.

The remedies for the disease may be divided into two categories, the local and the constitutional. In my opinion, as in my practice, I lean towards the former to the exclusion of the latter, with, however, this proviso—that by constitutional remedies I mean those such as copaiba, cubebs, sandal-wood oil, &c., which are supposed to exert a specific curative effect on the urethral mucous membranes, and not simple adjuvants—purgatives, salines, diuretics and so on—which are administered at certain stages of the disease for the relief of constitutional departures from health. Without hesitation I admit the utility of the latter, but for the cure of gonorrhœa I pin my faith to injections and local remedies to the exclusion of drugs administered for specific purposes by the mouth. I do not know that it is necessary for me to dilate on this point, for I have entered very fully into the discussion of the subject in my work on "Syphilis and other Venereal Diseases." I unhesitatingly declare myself to be a believer in urethral injections, and my opinion is founded on the results of the careful observation of many thousands of cases during the last thirty years in hospital and private practice.

The first indication obviously is, as in all forms of inflammation, to get the patient's constitution into the most favourable condition for the subsidence of the irritation: this is a matter which requires some consideration, and a careful study of the peculiarities of the individual. It is a mistake always to begin with purgatives and antiplogistics as a routine treatment, for although undoubtedly these are indicated in the case of a strong, healthy, and full-blooded man, they are of little use in a delicate, anæmic lad of feeble muscular and constitutional development, to whom a course of a reliable preparation of iron or even a basin of good soup would prove of more benefit than a dose of jalap or a black draught.

The local treatment in the form of an injection may be commenced at once, even when there is a great deal of inflammation and much scalding in passing water. I may say here that I am not in favour of the irrigation of the anterior, much less of the posterior, urethra, as advocated by many writers. I consider that injection, properly given and with a properly shaped glass syringe will answer every purpose, and this quite apart from the much greater convenience to the patient himself. The choice of a formula for injection is a matter of some importance, and for many years my favourite prescription was the following:—

Zinci sulphat., grs. 8 ;
Tinct. lavandul. co., $\frac{1}{4}$ dr. ;
Aq. rosæ. 4 oz. ;
Aq. distill. ad., 8 oz.

The strength of the injection is gradually increased as the patient improves. On the whole this treatment has yielded excellent results. Still it was not invariably successful, and on some occasions I was glad to fall back on acetate of lead, chloride of zinc, sulphate of copper, and permanganate of potassium. Even these were not infallible, and could not always be trusted to effect a cure.

Against the employment of nitrate of silver as an injection I must confess to having entertained a strong prejudice, for I felt some hesitation in using such a powerful caustic in cases in which I could not watch and control its effects on a mucous membrane so delicate as that of the urethra. I argued that a very weak injection of nitrate of silver might possibly be useful in an old gleet, but never in the course of gonorrhœa.

My attitude with respect to the use of injections of a solution of silver salt has, however, undergone a considerable change since the introduction of argyrol, which is a combination of argentum and vitellin, and although it contains 30 per cent. of silver it is, in my experience, absolutely free from all irritating effects. I have employed it freely at the French Hospital, where I have investigated its properties as an injection for urethral discharge. In this investigation I have been materially assisted by one of my colleagues in the out-patient department. Judging from my own experience of argyrol as a urethral injection I have no hesitation in saying that the results from its employment are distinctly favourable. In not one of my cases has it produced the slightest pain or irritation, either at the time of the injection or subsequently, although I have employed it when there has been profuse discharge and a large amount of inflammation and irritation not only in the urethra, but of the whole penis. This mode of treatment appeals to me strongly, for I maintain that the inflammation and irritation are due to the discharge, and that a bactericide which tends to allay the excessive secretion cannot increase the inflammation, but must of necessity lessen it. By using argyrol it is possible to obtain the local good effects of silver much more readily, and with much greater certainty and safety than with the nitrate; for argyrol is not caustic and may be employed even in a 20 per cent. solution without producing any irritation or deleterious effects. One of the most striking effects of the injection of argyrol is the prompt relief given to pain and smarting attending micturition. There is no doubt that it kills gonococci, and whilst curing the discharge probably lessens the risk of constitutional disturbance and of the occurrence of gonorrhœal rheumatism.

In illustration of these points I append notes of a series of cases recently under my care at the hospital. They were severe cases, and consequently afford an excellent test as to the value of the remedy. They were not specially selected, but were taken in the order in which they presented themselves for admission.

A man, æt. 23, was admitted with gonorrhœa, the incubation period of which had been four days. The discharge was profuse and of a creamy consistence, and the patient complained of ardor urinæ. There

was a painful swelling of the glands in the left groin. The patient was given a simple purgative and was ordered a 5 per cent. solution of argyrol, to be used as an injection three times a day. He was carefully instructed as to the method of using the injection, a point to which I attach paramount importance, as no injection can be expected to prove efficacious unless administered in an intelligent manner. On the twelfth day the discharge had completely disappeared. He was kept under observation in the ward for a few days longer as the enlarged glands continued painful and tender. As a precautionary measure he was given on leaving the hospital a supply of the injection to be used for a short time.

The result in this case was extremely satisfactory, for in my experience, gonorrhœa properly treated, even when all hygienic directions recommended are faithfully observed, often lasts two or three, occasionally six to eight, weeks, and then sometimes leaves behind a gleet, which is the bugbear of the surgeon and the *désespoir* of the patient.

The next case was a severe one from the fact of its being complicated with epididymitis. The patient, a man æt. 29, was admitted with gonorrhœa and left epididymitis. The discharge had been very profuse and thick, but had decreased in amount on the onset of the complication, a condition which I may remark is very common. A peculiarity in this case was that the patient affirmed that the discharge did not appear until three weeks after the last connection. He was an intelligent man, and his statement could not be shaken. The epididymitis was noticed ten days after the onset of the discharge. On admission, there was some elevation of temperature, the epididymis was very tender, but there was no marked tenderness of the testicle or penis. As in my opinion the best way of treating epididymitis is to cure its original cause, I prescribed a saline purgative and a 5 per cent. injection of argyrol, hot fomentations and belladonna being applied to the scrotum. Ten days after admission the discharge had entirely ceased, and there was so little tenderness of the epididymis that I ordered the testicle to be strapped preparatory to sending the patient out. Unfortunately the right epididymis became slightly tender and the discharge returned to a small extent. A repetition of the argyrol injection once more answered promptly, and in a few days the patient was completely cured. The second mild attack of epididymitis was clearly not due to the injection, for had such been the case, the original very acute and painful attack on the left side would have been aggravated.

The next case occurred in an anæmic subject, a man, æt. 24. He had a profuse gonorrhœal discharge, with a certain amount of ardor urinæ. The period of incubation was three days. He was given a saline purgative and an injection of a 5 per cent. solution of argyrol to be used three times a day. Seven days after admission he went out absolutely cured, there being no pain and no discharge. This I consider to be a very satisfactory case, for although there were no complications the patient made an exceptionally rapid recovery.

The following case illustrates the benefit of the treatment in the latter stages of gonorrhœa:—

A plethoric individual of sedentary habits, æt. 48, presented himself for advice at the end of the fourth week of the disease. He had taken capsules of various kinds, and had used a variety of astringent injections without, however, effecting a cure. It was not his first experience in this direction, and as in former attacks he had suffered from orchitis and other complications he was anxious to get well. The acute stage had subsided, but there remained a scanty mucopurulent discharge containing few gonococci. He was ordered a 5 per cent. solution of argyrol to be used as an injection twice a day, and retained in the urethra for at least from one to two minutes. He used only eight injections and then reported that the catarrhal condition had entirely ceased, and that the urine was free from shreds. He was seen again a week later, and

stated that there was no further need for treatment. The case is the more satisfactory as it is the mucous-terminal stage of gonorrhœa which is often so persistent.

The next case was one of mixed infection. The patient was a man, æt. 25, who had gonorrhœa for three weeks. The incubation period was two or three days from the last coitus, but it was clear that there had been a previous connection as the result of which he had contracted syphilis. He had a hard chancre on the penis with indolent glandular enlargement in the left groin. The gonorrhœa was treated with a 5 per cent. solution of argyrol as an injection, and was cured completely in a fortnight. The man was given anti-syphilitic remedies and told to attend as an out-patient.

It seems useless to multiply the records of these cases for they present a striking similarity and differ only in matters of detail. Equally good results have been obtained among out-patients and in private practice not only in acute cases but in those of long standing.

I have used chiefly the 5 per cent. solution, but after the first few days the strength may be raised to 10 or 20 per cent. without the slightest danger of producing irritation, even in acute cases. If the patient is seen quite early, that is within the first forty-eight hours, the abortive method which consists of the injection every three hours of a 20 per cent. solution may be resorted to with advantage. It is in the first few weeks of the disease, when gonococci are present in the secretion in large numbers, that argyrol exerts so beneficially its powerful antiseptic properties. In the sub-acute stage, however, when there is still a discharge, semi-purulent in character and containing a few gonococci it is better and safer to continue the argyrol injection until a complete cure is effected.

Among cases treated on these lines and without the administration of internal remedies the following have been observed. (1) A medical student, æt. 22, who had gonorrhœa with orchitis which was cured in a fortnight. (2) A man, æt. 25, who had had a thick, white urethral discharge for five months, and was cured in three weeks. (3) A man, æt. 28, who as a result of a gonorrhœa contracted nine years previously suffered from a morning drop (*goutte militaire*) which promptly disappeared after a 20 per cent. injection of argyrol. (4) A man, æt. 24, who had gleet with "*goutte militaire*" of over a year's duration, and was cured by six injections. In all these cases various other modes of treatment had been employed unsuccessfully.

In cases of gleet complicated with cystitis urethral injection alone cannot be relied upon to effect a cure, and the slight inflammation of the posterior urethra and of the neck of the bladder may advantageously be treated by the introduction of a 5 or 10 per cent. solution of argyrol into the bladder, allowing it to be retained for a short time and then to be passed naturally by the patient. This mode of treatment in which I generally employ strong boracic or quinine solution is with argyrol, free from danger and still more efficacious.

Speaking as the result of my experience I have no hesitation in saying that argyrol is a very valuable remedy for all kinds of gonorrhœa. One great advantage, in my opinion is, that in no case has it produced the slightest irritation or pain either at the time of injection or subsequently. It is a source of satisfaction to me that I have added argyrol to my armamentarium in the treatment of specific urethral discharges, besides it is an enormous advantage to have at one's disposal a silver preparation which, whilst curative, is non-irritative, and may be employed as an injection in all stages of gonorrhœa as well as in gleet.

It hardly falls within the province of this paper to deal with the sequelæ of gonorrhœa, but I may mention that in the treatment of gonorrhœal ophthalmia there is no more efficient remedy than the instillation of a few drops of a 5 per cent. (or even stronger) aqueous solution of argyrol.

THE RECENT FALL IN BIRTH-RATES :

ITS EFFECTS ON DEATH-RATES.

By C. R. DRYSDALE, M.D., M.R.C.P., F.R.C.S.

THE Registrar-General's report for 1877, page lxxxvi., tells how the mean rate of mortality in London for the thirty-eight years between 1840 and 1877 was 24 per 1,000 inhabitants. And yet, that was the time when sanitarians, like Sir Edwin Chadwick and Sir B. W. Richardson, had accomplished so much for the drainage and cleansing of London. Such praiseworthy efforts, however, were rendered nugatory, as regards the main aim of hygienists—*i.e.*, the lowering of the death-rate. The average birth-rate of London for the thirteen years prior to 1877 was 36 per 1,000 inhabitants. This birth-rate has greatly declined since 1877, for, in 1904, the birth-rate of all London was 27·9 per 1,000.

This fall in the birth-rate has occurred in almost all civilised countries since 1877, and its cause has been correctly attributed by Dr. Billings, of the United States Registry Office, to the voluntary lessening of the children to a family. One of the most modern cities, Chicago, U.S.A., with a population in 1902 of 1,608,000, had the very low birth-rate of 15·0 per 1,000 inhabitants, and a death-rate of only 13·5 per 1,000, so that the inhabitants of many cities in the United States have much lower birth-rates than London has at present.

The fall in the birth-rate has extended to most European countries and to our own favoured colonies. Thus, the births per 1,000 of the population fell since 1871 to 1895 in—

Germany	..	from	39·0	to	36·3
Austria	39·5	..	37·5
Holland	36·1	..	33·0
Great Britain	34·1	..	29·6
England (in 1901)					27·9
Belgium	32·2	..	29·2
France	25·5	..	22·6
Italy	36·8	..	36·3

All these States have had their birth-rates lowered. Not to speak of Germany, the fall in Austria was, in twenty years, 6 per cent.; in Switzerland, 7 per cent.; in Great Britain about 13 per cent.; in Holland about 9·0 per cent.; and even in France about 12 per cent. Our colonies have imitated us, for the birth-rate in Australia fell from 41 per 1,000 in 1861 to 26 per 1,000 in 1899, and in New Zealand a similar fall in twenty years took place.

What effect has this fall in the birth-rates produced in lowering the death-rates? In the decade, 1871 to 1880, Germany saw its death-rate fall from 27·1 to 23·3; Austria, from 31·5 to 27·8; Holland, from 25·4 to 19·6; England from 21·4 to 16·9 in 1901; Belgium, from 33·3 to 30·3; France, from 23·6 to 22·3 in 1895.

We see by these figures that the fall in the birth-rates of the civilised world has produced a great fall in the death-rates. The obvious meaning of these results is that, as the race of animal to which man belongs could easily double its numbers in about twenty-five years, there is always a pressure on food supplies, which causes the premature death of the less thoughtful classes who follow their instincts of procreation without due consideration.

High birth-rates in all European countries are the main cause of high death-rates, and especially

high infantile mortality, because they cause scanty feeding, crowding into great cities, and deaths from zymotics and phthisis—*i.e.*, high birth-rates are the main cause of poverty, which again is the origin of early death and disease. Sir Edwin Chadwick, in a pamphlet "On the Dwellings of the Wage-earning Classes," which he gave me in Paris in 1877, showed how misleading it was to talk of the death-rate of any large city. There were districts, he said, in London, where the death-rate did not exceed 11 per 1,000, while there were adjacent streets where the death-rate rose to 38 per 1,000. That able statistician, in 1843, made an inquiry into the district of Bethnal Green, when the death-rate of London was 24 per 1,000, as it was for more than thirty years subsequently. From this inquiry, it appeared that the gentry and professional classes of Bethnal Green had a death-rate from zymotics of 6.6 to all deaths, whilst the labouring classes had 22.2 per cent. There was a death-rate of 1 in 10 infants of the comfortable classes in their first years of life, and 1 in 4 among the labourers.

Dr. Villerme, of Paris, in 1834, showed that, between the ages of forty and forty-five the death-rate of persons in easy circumstances was three times lower than that of the poor of like ages. The late Dr. Janssens, of Brussels, gave similar figures for the rich and poor of Brussels. He showed that the families of the poor were thrice as numerous as those of the districts around the Park; and that the death-rate from consumption was 6.6 times as high in the poor streets as in the rich quarter. M. Lagneau, of Paris, mentioned that in the poor quarter of Plaisance, in Paris, the death-rate from phthisis was ten times as great as it was in the districts of the Champs Elysées. M. de Haussenville showed that the families of the poor in the poor districts of Paris contained thrice as many children as those in the rich quarters of Paris. Dr. Edward Smith found at the Brompton Consumption Hospital that the parents of the patients afflicted with that disease had given birth to 7.5 children on an average. The patients of the Metropolitan Hospital, when situated in Whitechapel, showed that one hundred married women over the age of forty-five had produced 740 children; whilst Dr. Lutaud, of Paris, gives the statement that the wives of the Parisian medical practitioners produce only about 150 children to one hundred wives.

Mr. Charles Ansell, of the National Assurance Company, estimated that in the year 1873 poverty destroyed 143,130 lives in England and Wales.

With regard to the death-rate of infants in the first year of life, Ansell found that among the richer classes in 1875, 80 per 1,000 of these children died; whilst we have heard that in several of our manufacturing towns, such as Preston, the infantile death-rate is sometimes as high as 400 per 1,000 born.

In the year 1898 the Board of Physicians of the city of Hamburg published some statistics relating to infantile mortality and the family income. In the well-to-do quarter of the city—Harvesthude—the average income per head was £141, and the infantile mortality was 2 per 1,000 inhabitants. In a poor district—Horn—the income per head was £15, and the infantile death-rate 10 per 1,000 inhabitants. In London, in 1874, the death-rates in the poor districts were much higher, as well as the birth-rates, than those pre-

vailing in the richer districts. The following are the birth- and death-rates per 1,000:—

Stepney	37.0	18.0
Finsbury	37.0	20.3
Bethnal Green .. .	35.7	20.3
Poplar	34.5	18.2
Westminster .. .	16.9	13.6
Hampstead	17.1	10.0
Kensington	18.0	15.0

These imperfect statistics prove clearly that the death-rate of the poorest classes is very much higher than that of the well-to-do classes, and that their birth-rate is twice and sometimes thrice as high. We may safely conclude that in European countries the main cause of high death-rates is large families, and that, if we really desire to improve the health of the classes at the bottom of society—which is the object of hygienic science—we must in future endeavour to persuade these unfortunate classes to have families not exceeding three or four children, as the richer classes are doing. If the birth-rate in this country were to fall to 15 per 1,000 and the death-rate to 12 per 1,000 that would give a surplus of healthy children of 126,000 annually, which would amply suffice for colonisation, so long as that temporary phase of society may require emigration. We ought to endeavour to reduce our infantile death-rate to 60 per 1,000 born, and extirpate phthisis and other *neoplasms of poverty*, so that all who are born may attain the ages of eighty, ninety, or one hundred years.

EARLY HISTORY OF THE MEDICAL PROFESSION AND OF HOSPITALS.—I.

THE earliest Greek medical operators, who, as surgeons, sought the Roman capital, where their services gradually became indispensable, deduced their origin from the most degraded of the conquered populace—such, for example, as attended on the public and private baths, servants in the gymnasiums of the diverse municipalities of Greece, or assistants in the Hellenistic pharmacies. Frequently these adventurers arriving from their country as slaves and bondmen, and quickly assuming at Rome the title and condition of freedmen, opened booths on the public streets, and offered their wares for sale—medicaments prepared by themselves. In these places the indolent and unoccupied assembled for the purpose of whiling away the time, and in quest of the news of the day. Consequently the practitioners of medicine at Rome presented no unusual attraction for the gracious respect of the citizens; and as the healing art remained in the hands of freedmen, it was regarded, indeed, as a vile and degraded traffic, suitable only for the servile condition of slaves. From whatever causes were developed Roman hatred, it appears to have extended back as far as the second century prior to the Christian era, to the time of Archagathus, a Peloponnesian surgeon who came to the city of Rome in order to exercise his vocation. From the Senate he received the right of citizenship, and a medical book purchased for him with public funds. He subsequently lost the respect of the patricians, and fell into contempt on account of the cruel nature of his surgical operations, which, as in more ancient times, consisted in cauterising and incisions.

Towards the age of Julius Cæsar, Greek physicians began to acquire greater privileges. One of the foreign surgeons who appears to have fully merited the considerable immunities extended to medical men at this period, Asclepiades of Bithynia, succeeded in grounding his curative system upon a philosophic or scientific basis. The medical economy of Asclepiades involved

largely the use of wine as a medicament, and frequent baths of cold water as a sanitary element. During the government of the Roman Commonwealth by the Senate, in early ages, the practitioners of medicine possessed, as a body, no legal status. The enlightened policy of Julius Cæsar elevated the character of the surgeons and physicians of the metropolis by conceding to them the franchises of citizenship. By such judicious concessions, this valuable profession was at once made honourable in the eyes of the people, and henceforth stood forth as an avocation which had obtained the honours of specific illustration at the hands of the celebrated warrior and statesman.

Of the scholars of Asclepiades, Antoninus Musa was, without question, the most worthy, inasmuch as his successful treatment of the future Emperor Augustus, by means of cold lotions and saturated wraps, saved him from a dangerous illness. Of all the prerogatives with which the devotees of medical science had been previously endowed, none equalled the grateful immunities of Augustus after his preservation by Musa. By a rescript promulgated by the Imperial authorities, all surgeons were declared thenceforth for ever free from public impositions of every description and enfranchised of all taxes, while at the court of the emperor a highly salaried surgeon was regularly engaged. Such arrangements unquestionably largely aided in permanently establishing the social dignity of members of this association, and contributed to the development of medical science. After the time of Julius Cæsar, great numbers of Greek surgeons were domiciled in Rome about which period the names of several army surgeons of this nationality appear. The quaint notice is made of surgeons recruited for the Roman legions under the distinctive nomenclature of *medici legionum* and *medici cohortum*.

Soramus, surnamed the younger, in order to distinguish him from the renowned physician of the first century, prepared an elaborate work on obstetrical treatment, a branch of surgery anciently entrusted to female care, and in the Roman Empire regulated by proper legislation. Soramus the younger is known as the oldest historian of the curative art. Moxhion, apparently his disciple, distinguished himself as the author of the first treatise on midwifery, entitled "*De Mulierum Passionibus Liber*." He especially cautioned in such cases against an antiquated custom of severing the umbilical cord with a wooden or glass fragment, but in the place of these directed the use of a sharp blade. Roman zeal for the cultivation of a taste for natural history and the kindred science of medicine, influenced two illustrious citizens of the Empire to acquire the mastery of the entire range of contemporary sciences, and, although subject to the curious superstitions of the age, to become profoundly skilled in a knowledge of the curative art. Of these, Aulus Cornelius Celsus, in the time of Augustus, carefully collated an enormous encyclopædia, of which the sections treating of medicine are yet extant in eight books ("*De Medicina, Libri Octo*"). In this work we possess a fine specimen of the intellectual industry and scientific research of an enthusiastic scholar; he has collected the wisdom of preceding ages and aggregated in exact adjustment the productions of learning of Hippocrates and Asclepiades, Archagathus, and Israelitish and Arabic physicians.

The other celebrated scholar, Caius Plinius Secundus, of Como, on a more enlarged scale, indeed, than Celsus, mastered the entire range of natural science and arts, and reduced them into encyclopædic form. The thirty-seven books of natural history present a marvellous repertoire of manifold wisdom. The principal object of the curative art seems to have been the invention of unusual remedies, strangely compounded, while the medical adviser assumed the attitude of a professional empiric. Out of this system grew unnumbered receipt books prepared for practical use, the value of which was attested by actual experiment. None of these collections attained the celebrity enjoyed by the comprehensive work on "*Herbal Medicaments*" of Dioscorides, a native of Anazarabia, in the reign

of Nero. This compilation maintained its repute with undiminished vitality through the Middle Ages to modern times. Among the vegetable remedies known and recommended by Dioscorides, were ginger, pepper, aloe, sugar or saccharine matter, &c. In addition to these he suggests the free use of elm bark against pustular maladies. Rules were established by him for the prompt detection of adulterated medicaments, while his intimacy with metallic remedies, whose preparation evidently required an apparatus of fine implements, presupposes a knowledge of chemical action.

To the epoch of Christian emperors must be assigned the first serious attempt at medical organisation. This rapid increase of surgeons ultimately necessitated their subjection to a supreme head whose dignity was designated as *Archiatrus popularis*, whose official duty was identical with that of a physician salaried by the State. For the purpose of establishing the lawful privileges of this professor on a basis of correlative duties and substantial enfranchisement, the Emperor, Antoninus Pius, about the middle of the second century, issued an edict in the nature of a medical ordinance, which prescribed that cities of the smallest number of inhabitants should be entitled to have and maintain five physicians absolutely freed of all and every kind of public service, intermediate towns and villages were privileged to possess seven, while the largest metropolitan cities obtained an enlargement of privileged surgeons to the number of ten, within the municipal limits of the great capital of the Empire, each of the fourteen *regiones* or departments was allowed a medical attendant whose salary was fixed by law. The Vestals and Gymnasia also were permitted a surgeon regularly employed at public expense.

Compensation for professional skill consisted chiefly in kind—*annonaria commoda*, or natural productions, sometimes in money or its current equivalent, usually styled *salara*, as distinguished from the honorarium or fees, which more accurately applied to the law than to medicine. Upon the principle of receiving State or Government patronage, the members of the medical profession thus salaried were likewise obliged to perform certain functions partaking eminently of a public service. Consequently, it was their official duty to render attendance to the impoverished without compensation—a system of absolute necessity arising from the disinclination of the affluent and aristocratic Romans to subject himself to the hazard of infection, which was carefully avoided on the return of the messenger to sick friends, by compelling the servant to bathe himself before presenting the result of his inquiry. In the case of wealthy sufferers the departmental physician was allowed to demand his honoraria, or fees. To these emoluments arising from their official position, municipal surgeons added the substantial benefits of the dignified *Archiatra*, by an exemption from such imposts as military obligations, quartering, forced loans, &c. In matters requiring judicial inquiry, these privileged officials were favoured with a speedier disposition of their causes before the tribunals where they were called—a prerogative of the highest value under the complicated and tedious proceedings which the Roman advocates were skilled in prolonging in exact proportion as the gilded honoraria of the clientele failed to stimulate his judicious hesitancy. Antoninus Pius enacted that these public surgeons should be exempt from summary process and interdicted the issuance of a warrant against them to bring their body before the Courts. This rescript was reaffirmed by Constantine in the year 321, under most exemplary fine and the penalty of being flayed alive.

Towards the commencement of the third century an edict was promulgated which rendered medical practitioners responsible for the pathological treatment of their patients and forbade for such purpose the application of magic. Permission, however, restoring certain remedies of a magical nature was subsequently decreed by Constantine the Great in the year 321. In order to hold in subjection a tendency so rapidly increasing at this epoch, to apply supernatural curatives, a law was passed adjudging the delinquent to the death penalty.

One of the most singular and, in its moral influences on the Roman society, destructive customs, traceable to the deteriorating presence of Greek refugees in the Imperial metropolis, was the universal extension of the emasculation of infants to qualify them for a terrible servitude. The mortality of this deformity may be conjectured when it is stated that only one of thirty survived the mutilation. Severe laws were promulgated by the emperors in order to totally extinguish this inhuman practice. The penalties inflicted for violating these ordinances were emasculation by way of retaliation, banishment, and confiscation of the offender's personal possessions.

Towards the conclusion of the third century the first indications present themselves of the existence of a class of citizens to whose vigilant care was confided the preparation of medicaments ordered by attendant physicians. Prior to this epoch, for several centuries it had been the most usual method for medical practitioners to compound their own medications and administer them to their suffering patients. Regular pharmacists were entirely unknown, excepting perhaps the *Herbarii*, who disposed of their commodities at trifling prices in the public markets or along the highways. There was, indeed a class of medicinal compounders whose operations were mainly limited to the preparation of such remedies as experience or current rumour suggested to be most suitable for popular merchandise, and offered their wares upon benches or stalls, in booths denominated *apotheca*, directly for public sale. For this reason they were classified as *medici sellularii*, but the market vendors of medicaments by outcry were known as *medici circumforanei*, or *circulatores*. Physicians themselves, in preparing proper remedies for their sick, usually purchased pharmaceutical supplies from these medicinal merchants.

CHRONIC PROSTATITIS AND TREATMENT.

CHRONIC inflammation of the prostate gland, a very frequent affection of which the consequences can be so important, occupies but a very restricted place in classical works. It is only within the last few years that it has taken a prominent place in urinary pathology. Dr. Le Fur made some interesting communications on the subject at the French Society of Urology, of which the following is a *résumé* :—

From an etiological point of view, chronic prostatitis may be divided into two classes—infected and aseptic prostatitis. The former is characterised by the presence of microbes and pus in the secretions of the gland, while the latter can be primary aseptic (absence of microbes or pus), consisting in modifications of the glandular secretion (hypersecretion, secretions modified in their chemical composition), or aseptic after infection of the gland, due for the most part to gonorrhœa.

The causes of infected prostatitis are numerous: Gonorrhœa, stricture, hypertrophy of the prostate, traumatism (introduction of instruments, injections), urethritis, non-bleorrhagia, cystitis, pyelo-nephritis, acute enteritis, muco-membranous entero-colitis, hæmorrhoids, constipation, stricture or cancer of the rectum.

Other causes are due to general infection: Grippe, mumps, typhus, measles, tonsillitis, arthritism, &c.

Aseptic chronic prostatitis is characterised by hypersecretion of the gland, dilatation of the glandular acini and retention of the products of the secretion in the glandular cul-de-sacs.

The causes are: Abuse or privation of genital excitement, masturbation, prolonged or interrupted coit, stricture (aseptic) of the urethra, hypertrophy of the gland. Nearly all the cases that have become secondarily aseptic were consecutive to bleorrhagia.

Out of forty-six personal cases, minutely recorded by Dr. Le Fur, thirty-eight had a gonorrhœal history, fifteen had orchitis; five, an abscess of the prostate;

twenty, large strictures; one, phimosis; while the cause was attributed to catheterism in five cases, and urethral injections in four cases.

The symptoms of chronic prostatitis are frequently obscure and attenuated. Pain is generally slight, vague, and diffuse. It is only in exceptional cases that it becomes violent, giving the sensation of a cut or a tear; in the majority of cases it consists in a sensation of weight, shooting pains in the perineum, irradiating to the anus, the inguinal regions, the back; but very frequently no pain or trouble is complained of.

The troubles of micturating were also very variable; in thirteen of the forty-six cases they were absent, but in the majority of cases frequency, both diurnal and nocturnal, of micturition was observed, and in twelve cases difficulty was experienced, especially in the morning; the patients had to wait more or less for the flow. Acute retention of urine was noticed in six cases, and in fourteen cases the urine was clouded from pus and microbes. In fourteen cases erections were frequent, especially at night, and spermatorrhœa and prostatorrhœa were observed in three cases.

The diagnosis of chronic prostatitis is generally easy to make by the method recommended by Dr. Le Fur. An experiment should be made first with three glasses to find and collect the filaments of urethritis (first glass), and to confirm the existence of more abundant filaments in the second and third glasses (a good sign of prostatitis). Examination by the rectum should then be made, the finger protected by an india-rubber cap. By this means the prostate and the seminal vesical are examined and massed; in this way the prostatic liquid can be collected directly from the meatus, or the urine after massage of the gland, containing the prostatic secretions; a macroscopic examination should be made at first and afterwards a microscopic examination, by which exact information will be obtained on the physiological and pathological condition of the gland. However, chronic prostatitis can be confounded with other affections; it can simulate syphilis, tuberculosis of the prostate, or a renal affection, and is frequently complicated with stricture.

Treatment.—The treatment of chronic prostatitis consists essentially in massage, digital or with an electric masseur invented by M. Le Fur; large dilatation and irrigation. The bougies should be very large (60, 70, and even 80 Bénéiqué). The irrigations should be done with a solution of nitrate of silver (1:1,000), and give excellent results. However, if the dilatation cannot exceed 45 or 55 Bénéiqué, urethrotomy should be performed, which always succeeds. Perineal prostatectomy constitutes exceptional treatment. The condition of the intestines should be looked after, as constipation aggravates the symptoms, and is not infrequently a cause of chronic prostatitis.

THE MODERN METHOD OF TREATMENT BY TUBERCULIN.

THE *Deutsch. Med. Zeit.*, No. 64, has a reference to a paper on this subject by Dr. A. Feldt. The leading lines of the treatment are, according to the author, (1) very slow augmentation of dose and even then when the dose hitherto employed has caused no reaction; (2) diminution of the dose when the reaction from any specified dose has ceased to appear; (3) sufficiently long interval between the individual injections; (4) the utmost possible avoidance of severe general reaction with more or less grave symptoms. As transient immunity to tuberculin is very easily set up, long pauses should be made in the treatment now and again, after which, if the patient is not cured, reaction generally takes place to a dose much smaller than the one employed in the previous stage. A patient who will not react to a c.cgrm. several months after the last course may be looked upon as cured.

When, therefore, tuberculin has found a place in sanatoria and patients have been passed on from

these to country residence for treatment in the country, it is plainly indicated that they should not be treated expectantly or with guaiacol, but should continue the tuberculin treatment. The commencement of a tuberculin course is contra-indicated after hæmoptysis, and with any considerable tendency to hæmorrhage. It is only relatively contra-indicated, however, in feverish cases and patients going about. Patients going about are unsuited for the treatment only when external circumstances—mental capacity or lack of education—do not allow of sufficient self-observation. The quintessence of modern views on tuberculin as they are crystallised amongst specialists in this branch are formulated thus: Tuberculin is a remedy to be often avoided, but which should be used at times, a remedy of incalculable value, which has at times been discredited by misuse, but which will in the future be perfected, but must never be forced. Its employment demands much more than the possession of a subcutaneous injection syringe and a table of doses.

No. 63 has an article by W. Reichmann on
THE TREATMENT OF ROUND ULCER OF THE STOMACH BY FASTING.

Probably more medical men employ fasting as part of the treatment of these cases of ulcer of the stomach, but few probably consider it the most important agent. The author says that pain and hæmorrhage frequently persist or return after the use of even the most approved remedies. Under such circumstances he looks upon complete abstinence from food and drink at least by the mouth as the most effective method of treatment.

Before all, he enjoins absolute rest in bed. The patient is not only forbidden food and drink, but he must not even swallow his saliva. To avoid the feeling of dryness in the throat he is allowed to gargle frequently, and nourishment and the needful liquid are to be given by enemata. First of all, for a day or maybe two, in order to induce tolerance on the part of the bowel, only plain water is given in small quantities, not more than 5 ozs. or 6 ozs.; or salt or a small quantity of opium may be added. Later on 5 ozs. of broth may be given, to which are added two raw eggs, and $\frac{1}{2}$ drachm of salt. Two to 3 drachms of grape sugar may be added, and a dessertspoonful of brandy or a tablespoonful of strong wine. In addition to the above, in order to keep down peristalsis, 3 to 8 drops of tr. opii may be added. The enema may be given twice or three times in the twenty-four hours.

Such a diet is naturally insufficient, but considering the absolute rest and the small amount of force expended, it may be made to serve for from ten to fifteen days. The treatment is rarely called for for a longer period, and the pain generally disappears after two or three days' abstinence.

It must be borne in mind, however, that this method of treatment has its disadvantages, as neurasthenic patients do not bear fasting, and it sometimes leads to great prostration and even fainting attacks. These disturbances may be so great that the plan must be discontinued.

Another unfortunate symptom that may come on is parotitis, which the author has seen three times. It is supposed to arise from collection of a pathogenic microbe in the mouth and should be guarded against by careful disinfection.

He recommends that the fasting treatment should not be commenced until the usual remedies have been tried and have failed.

ULCUS VENTRICULI AND HYPERACIDITY OF THE STOMACH: THEIR TREATMENT BY OLIVE OIL.

The same journal contains a reference to a paper by Dr. A. Koehler, of Teplitz, on the above subject. He employed the oil treatment in cases of both organic and spastic stenosis of the pylorus and duodenum, and their sequelæ—dilatation of the stomach. The results were favourable. Whilst the oil arrested spasms and lessened secretion, and therefore the hyperacidity accompanying ulcer of the pylorus, it had also an extremely favourable effect in inoperable carcinomatous ulcers of the stomach.

In many cases, however, the treatment was not well borne, owing to the almost invincible repugnance some have to swallowing crude oil. For such cases, he devised sterilised gelatine capsules containing three and five grammes respectively, so that ten capsules of five grammes each corresponded to three tablespoonfuls of oil. One advantage of this method of administration was that all the medicine reached the right spot for local action.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, August 19th, 1905.

CROATIA AND ITS HEALTH DEPARTMENT.

The following may be interesting to English practitioners who, according to report, are complaining bitterly of the waning profession. A comparison with Croatia, however, has to be taken with many modifications. Salaries are small, but domestic expenses are correspondingly low. It need not be repeated that the greater number of medical men in Austria are under Government control. Croatia, for instance, is a principality of Austria and closely connected with Hungary, though perfectly distinct in its political government. The health department is therefore under the authority of the Croatian Government, which is, first of all, presided over by a proto medicus, under him a technical adviser, with a president of the county sections. These, according to Government authority with official classifications are all placed in the sixth rank. Coming after these officials is a medical secretary, with a large number of promising young men on his staff. He is placed in the seventh rank of medical merit. We come now to the workers of the medical health department, who have recently had a grievance to ventilate, owing to these classes having been divided between eight and ten in merit. Croatia contains 2,380,000 inhabitants, who are divided into eight "komitates," or communes, with a "komitatsfiskus" belonging to the eighth rank of merit. Again, each of these "komitates" has ten districts, with a medical man to each district. It is amongst this class of district men where the greatest discontent exists, owing to some of them being placed in the ninth rank, while others equally good are placed in the tenth rank. The cry has gone forth that it is degrading to the profession, and that these district doctors should be raised to their former position.

The value of this rank may now be estimated when we begin to consider salaries. The "bezirksaerzte," belonging to the tenth class, have 2,000 to 2,200 kronen per annum, equal to £80 to £88 per annum, while those of the ninth rank have 2,600 to 2,900 kronen, with the addition of 300 to 400 kronen for residence. This may give the reader an idea how the health department is conducted, although there are a number of other medical officers in more subordinate positions who conduct parishes and smaller divisions with a salary of 14 to 20 kronen. In these large districts there is another set of public officers, but not belonging to the same department, and whose duties are closely allied to them in the same districts. Properly speaking, the latter may be called parish doctors. Although having different degrees, they have each their appropriate duties, often coming in conflict with the health department. The private practitioner here is almost a negative quantity. This officialism has its advantages, as old-age pensions, though small, are provided for the old and infirm doctors.

DIFFERENCE BETWEEN NORMAL AND IMMUNE AGGLUTININ.

Landsteiner and Mathias, at the Pathological Institute, have been endeavouring to distinguish the relationship between the normal serum and the immunised serum. These two are generally recognised as one and the same, although Reisenberg, Gruber, and Volk have disputed their similarity. According to Landsteiner's experiments, the splitting of the union in the hæmagglutinin and blood corpuscles is very different, as the immunised agglutinin is much

more difficult to separate than the normal agglutinin. The clumping of the blood corpuscles with the normal serum can be broken up by simply warming, while the immunised clumping requires sodium chloride and as strong heat to break it up.

THEORY OF BIOLOGICAL RAYS.

Schlichta has advanced another theory, or rather attempts to confirm many others, that the intracutaneous injection of different substances, such as alkalies and acids in specific doses will produce tissue changes of a pathological nature identical with the rays emanating from radium and the Röntgen machine. The erosive power of the rays may be equal in result, but he is still unable to explain a series of characteristic operations, which have less healing power under the use of the injections than those of the rays themselves.

Operating Theatres.

NORTH-WEST LONDON HOSPITAL.

CASE OF PYÆMIA AND MIDDLE EAR DISEASE.—Mr. M. COLLIER demonstrated a case of middle-ear disease having points of peculiar interest. It was one of chronic mastoid suppuration followed by general pyæmia. The patient was a woman, æt. 68, who was admitted to the hospital suffering from a large abscess in the left axilla following an attack of pain in the left ear, which had previously discharged for many years. The patient stated that she had suffered from this discharge for a great many years. At long intervals attacks of pain had occurred in the ear, confining her to the house or bed for several days. The pain usually subsided following a free discharge. She said that ten days before admission she had had an acute attack of pain in the left ear with pain and tenderness behind the ear; this had to a large extent subsided, and was followed by pain and tenderness in the left axilla, for which she sought admission. On admission the woman was seen to be of spare build, looking very much older than her years, and she had a sallow yellow complexion. There was an offensive copious discharge from the left ear, but no tenderness of the mastoid, no œdema of the tissues in the neck, no definite eye symptoms, and no paresis; the lungs and heart were apparently unaffected, and there was no abdominal swelling or tenderness. The swelling in the left axilla had evidently suppurated. The temperature was slightly raised. The swelling in the axilla was opened on the next day, and tonic and supporting treatment employed. On the evacuation of the contents of the abscess, the local condition quickly improved. On the tenth day after admission a swelling appeared in the right lumbar region followed by marked evening rise of temperature. This quickly suppurated, and was opened and drained. A few days after the right knee-joint began to swell, and this was accompanied by pain and tenderness, and fluctuation; the passage of a hypodermic needle revealed thin pus; the knee-joint was then freely opened and drained; unfortunately the condition of the right knee-joint was followed by pain and tenderness in the right shoulder-joint. On pus being diagnosed this joint was opened freely and drained. The patient's vitality all through these various procedures appeared quite inconsistent with her wretched general condition. The temperature all through rose but slightly above the normal, and the woman died, worn out by suppuration, within the following fortnight. Mr. Collier said that in reviewing

the history and facts of the case at first the association of the ear trouble with general pyæmia was a matter of speculation. There was no definite evidence of involvement of the lateral sinus; the absence of cerebral symptoms did not support the theory of infection from the tympanic cavity. The fact of an abscess appearing in the axilla associated with recent ear suppuration need not be looked upon in the relation of cause and effect; the question whether the mastoid should have been opened on admission to hospital had been discussed; in the absence of a positive diagnosis it was deemed wiser to treat the ear on general principles and to open the axillary abscess and get the patient in a better state of health before attacking the mastoid. The subsequent course of events left grounds for doubt whether the pyæmia was not due to the ear trouble; it was possible, however, that pyæmia may have followed and been secondary to the axillary abscess and the subsequent pyæmic infection of the joint again secondary to this. In the unfortunate absence of a postmortem examination, the true facts of the case could not be ascertained.

ACUTE SUPPURATION OF BOTH TYMPANIC CAVITIES FOLLOWING DIVING IN THE SEA.—The same surgeon operated on a case of acute middle-ear suppuration following diving. The patient, a young man, æt. 29, after diving in the sea from a height, was seized the same evening with pain and deafness in both ears. He was attended by a local practitioner, and after three days of intense agony a discharge appeared from the right meatus followed by cessation of the acute symptoms in that ear. The left ear was more obstinate to treatment, the pain and tenderness increasing with a gradual exacerbation of all the symptoms. The man was sent up to town and admitted into the North-West London Hospital. On admission the temperature was 103.5°, there was great agony located in and behind the left ear; the auditory canal was so swollen that the drum could not be seen. The anterior wall of the mastoid antrum was bulging in to the auditory canal, and the whole of the tissues in a state of œdema. Under an anæsthetic, Mr. Collier introduced a fine curved tenotomy knife into the auditory canal, incised the drum at its posterior and lower segment as well as the tissues forming the anterior wall of the mastoid antrum. This was followed immediately by a copious discharge of pus, and much relief to the symptoms. The interest of the case, Mr. Collier said, centred on the cause. He pointed out that the introduction of sea-water into the auditory canal is often followed by acute suppuration of the mastoid cavity without previous affection of the mastoid contents; and the question of how and why this takes place is not altogether apparent; whether a direct infection occurs *via* the auditory canal or *via* the Eustachian tube is a matter of speculation. The difficulty of infecting the tympanic cavity through a whole and sound membrane could not, he thought, be lightly discarded. A more rational view of the causation, he said, might be that water enters the tympanic cavity *via* the Eustachian tube, having entered the nose or mouth during immersion. The intensity of the symptoms in these cases he remarked could not be explained by the mere pressure and injury caused by the condensed air in the auditory canal. Mr. Collier also said that prompt incision of the drum in these cases would save much misery and probably in many cases complete loss of hearing.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 23, 1905.

POOR LAW COMMISSION.

It is good news to everyone who has considered the subject that the Government propose to appoint a Royal Commission to inquire into the working of the Poor Laws; for the administration of the 1834 Act and the subsequent measures that have been committed to the management of the guardians need thorough overhauling in the light of seventy years' experience. Medical men, both as citizens and as professional men, have much concern with the means by which the social wrecks and derelicts of their country are dealt with, and a large number of doctors are employed in one capacity or another as servants of the boards of guardians. These latter will be intimately affected by any changes that are proposed, but from the national standpoint their colleagues will be no less interested, although their own positions will not be involved. It is much to be regretted that a step of such momentous importance was decided on at a period of the Session which did not admit of its full discussion, and that the terms of reference and the composition of the Commission could not be announced till after Parliament had risen. In the first place we may be allowed to express the hope that the members of the Commission will not be appointed on political grounds, as the one thing the average politician knows least about and cares least about is, if we except the cause of public health, the business of the Poor Law. The local doings of the guardians are considered unworthy of the notice of men whose palates crave for the sensations provided by African intrigues and storms in Asiatic tea-cups. But as affecting the national health and prosperity, on which all foreign relations ultimately depend, there are few matters of more vital moment than the prevention of pauperism among the working classes and the maintenance of that abounding self-sufficiency on which the edifice of the British Empire has been built up.

The able-bodied pauper is a disgrace to any civilised country, and that his existence should be tolerated in the workhouses of the country bespeaks a lamentable hiatus in the machinery that caters for the poor; he may be unfortunate, in which case provision for his needs should be made in other ways than at present are available; he may be vicious or idle, in which case he is no fit associate for the worthy, worn-out worker who is passing the evening of his days under care which he well deserves. The recognition and certification of men as able-bodied is essentially a medical duty, and for this and many other cogent reasons it is necessary that the medical profession should be well represented on the Commission. Expert advice, too, is greatly needed with regard to infirmaries, which constitute an integral part of the workhouse equipment. We have often had to draw attention to the inadequate staffing of some of these infirmaries, and it would be well that a definite minimum number of nurses should be assigned to a definite number of patients. The treatment of the sick poor should doubtless be conducted on economical lines, but it is more than a tiresome addendum to the guardians' work, to the medical man, at least, it appears as a sacred duty. Another subject we should like to see definitely taken in hand by the Commission—namely, the utilisation of the clinical material of the infirmaries for the instruction of students and post-graduate classes. It is a revelation to many medical men whose knowledge of disease has been gathered in general hospitals to find in the wards of infirmaries crowds of sufferers from chronic maladies which they had been accustomed to regard as clinical curiosities. These infirmaries present vast unworked fields for diligent and enthusiastic young men, and not only might such men add greatly to their own clinical knowledge by studying in infirmary wards, but they might work out in detail many of the theoretical suggestions that they had learned from their teachers—to the great advantage both of the patients themselves and humanity in general. If some scheme could be devised by which the administrative work of the infirmaries remained in the hands of the superintendent and his subordinates, while the clinical care and treatment of the patients devolved largely on recently qualified assistants, it might be possible that every medical student had the opportunity of holding a resident appointment after graduation. There is a further matter that we hope will come within the terms of reference to the Commission, as it presents one of the most glaring anomalies of Poor Law administration; we mean the carrying out of the Vaccination Acts. Vaccination is peculiarly and entirely a matter of disease-prevention, and should belong to the province of the sanitary authority who are charged with the care of the health of the community. Administered by the boards of guardians as these Acts now are, the utmost confusion reigns in small-pox outbreaks when it is the duty of one authority to isolate patients and

of another to vaccinate contacts. Moreover, in districts in which anti-vaccinators are prominent, the return of guardians is made to hinge on their support of an opposition to vaccination, a matter which is easily arranged by an interested clique in elections which excite so little interest as do those of the guardians. A much broader view is taken of the qualities of a town councillor, and his election is determined by other circumstances. For many reasons, then, we trust that a strong medical element will be found in the composition of the Royal Commission.

THE CAUSE OF LEPROSY.

RECENT advances in bacteriology have so completely modified our ideas of the causes of many diseases that one scarcely expects to find any survival of a belief in those etiological factors of disease which satisfied our predecessors of two hundred years ago. From the fifth century down to as late as the end of the fifteenth century leprosy was a common disease in Ireland, as is attested by the numerous leper hospitals or houses that were established throughout the country. The leper-house at Waterford, which was confirmed to the poor of the city by a charter of King John in the year 1212, continued in use as a leper-house till 1740, when it was converted into a public infirmary, and is at present used as the Waterford County Infirmary. On May 15th, 1903, Mr. Jonathan Hutchinson, at a meeting of the Polyclinic, strongly advocated the view which he had previously put forward, that "leprosy is in some way connected with the eating of fish in an uncooked state—and often decomposing state." And, further, "it is suspected that the fish food of this kind, uncooked, may either carry the bacillus itself, or may be the stimulant which excites it to action." In this connection the following extract from Boate's "Natural History of Ireland," is of interest:—"The rickets are of late very rife in Ireland, where a few years ago unknown; so, on the contrary, it hath been almost quite freed from another disease, one of the very worst and miserablist in the world, namely, the leprosy, which in former times used to be very common there, especially in the province of Munster, the which therefore was filled with hospitals, expressly built for to receive and keep the leprous persons. But many years since Ireland has been almost quite freed from this horrible and loathsome disease, and as few leprous persons are now found there as in any other country in the world; so that the hospitals erected for their use having stood empty a long time, at length quite decayed and come to nothing. The cause of this change is not so obscure nor unknown as it is in most other changes of that nature. For that this sickness was so general in Ireland, did not come by any peculiar defect in the land or in the air, but merely through the fault and foul gluttony of the inhabitants, in the successive devouring of unwholesome salmons. The common report in Ireland is, that boiled salmons eaten hot out of the

kettle in great quantity, bring this disease, and used to be the cause why it was so common; and some famous authors have not stuck to relate as much for a truth. But that is a fable, and salmons have not that evil quality, which way soever they be eaten and prepared, but when they are eaten out of season, which is in the latter end of the year, after they have cast their spawn, upon which they do not only grow very weak and flaggy, but so unwholesome, that over their whole body they break out in very filthy spots, just like a scald man's head, so as it would loath any man to see them; nevertheless, the Irish, a nation extremely barbarous in all the parts of their life, did use to take them in that very season, as well as at any other time of the year, and to eat them in very great abundance, as easily they might, every river and rivulet in most parts being very full of them, and by that means that horrible disease became to be so common amongst them. But the English having once gotten the command of the whole country into their hands, made very severe laws against the taking of salmons in that unwholesome season, and saw them carefully observed, whereby hindering those barbarians against their will to feed on that poisonous meat, they were the cause that that woful sickness, which used so mightily to reign amongst them, hath in time been almost quite abolished, which great benefit, with so many others, that hateful people hath rewarded with seeking utterly to exterminate their benefactors." Gerard Boate, was a Dutchman, and with his brother, Arnold, was educated at Leyden. Subsequently he practised physic in London, but came to Ireland on the invitation of Archbishop Usher. Boate was appointed Physician to the State, and died in office shortly after his appointment, on January 19th, 1649. The book, from which the above quotation is taken was written before he came to Ireland, though not published till after his death—1652. The book was re-issued in Dublin in 1755, and it is from this edition that the quotation is taken. Boate is not looked on by subsequent writers as a reliable authority in matters of Irish history, and we fear that his explanation of the cause of leprosy will not find much more support among the profession than will his appreciation of our countrymen find among his modern Irish readers.

HERACLITUS, 1905.

THE philosopher who at the end of the world puts the finishing touches to the history of thought is likely to find his mind impressed more by the essential sameness of human speculation than by its apparent variety. It is, on the whole, more true that there is nothing new under the sun, as set down by the Hebrew aphorist, than that invention is endless, and it is a passing tribute to human ingenuity that with the same materials it is able to fashion and refashion such a puzzling multiplicity of figures. The history of civilized peoples is, allowing for time, circumstances, and national idiosyncrasy, merely a

repetition of the same phenomena in different settings, and this is no less true in the domain of thought than in any other department of the life of an organised polity. The process and the steps by which development proceeds are the same; it is only the local colour that varies. Moreover, since thought has become capable of embalment in literature, each generation of successive states has been able to profit by the experiences of its forbears; in a word, to begin where they have left off. But though fresh factors are brought into the working of the problem the principle of resolution is much the same as it was before their introduction. Modern science, it is fashionable to consider, is a new feature in the history of the world, and it would ill become medical men to neglect those principles of thought which have rendered modern scientific achievement possible, but the fact remains that, apart from its practical bearings, scientific discovery and research tend rather to exemplify and corroborate, and lend exactness to the theories of the philosophers of ages past than to create new modes of thought or essentially novel speculation. If, as Protagoras maintained, man is the measure of all things, all things can only be measured by man's mind, and as man's mind in finite, it is not surprising to find him continually arranging and rearranging his conceptions of things in similar circles in different ages. The presidential address at the annual meeting of the British Association is generally looked to to provide a broad sketch of the position that scientific thought has reached, and Professor Darwin's address at Cape Town this year fully maintains the high standard attained by his predecessors. It was perhaps natural, as expressing in concrete form the advance of four centuries of acquired knowledge, that the lecturer should have instanced the shortening of the journey to the Cape, which took Bartholomew Diaz sixteen months of battering in a crazy brig, and Professor Darwin and his colleagues a fortnight's lounging in the saloons and smoking-rooms of a 13,000-ton ocean steamer; and that from this striking exemplification of the power man had acquired over nature he should have proceeded to dwell on the astonishing rapidity with which new marvels of discovery take each other's place in the gaze of mankind with each succeeding year. But from this introduction, Professor Darwin proceeded to plunge into the less sure region of speculation as to the future, basing his forecast on the probable continuance of action of the same causes that have operated in the past. That speculation forcibly led to the conclusion that no elements are eternal, for in spite of all that was taught and held till a few years ago, the elements have not proved stable in the past. Only those that are comparatively well adapted to the conditions of the earth are capable of survival, the others arranging and re-arranging their component elections till some new and more stable product results from their activity. The atom is no longer conceived of as being indivisible,

but on the contrary is composed of separate corpuscles (or electrons), which may be described as particles of negative electricity, and these electrons, though acting with mutual repulsion towards each other, are preserved from disruption by some force such as that provided by a positive electric charge. But even the stability thus ensured is only a comparative quantity, for the electrons must eventually dissociate and help towards the formation of new atoms, even though their association in the original atom has been maintained during thousands of revolutions in the same orbit. In radium and the associated elements possessing very complex atoms this breaking up and spontaneous rearrangement of electrons can be actually observed, and thus transmutation of elements is practically demonstrable. It follows, therefore, that the resulting relative stability of certain atoms and the relative instability of others is due to the operation of the Darwinian force—natural selection. A safe parallel to this perpetual mutation of the components of the atom is presented by the political constitution and mutability of states, which rise, last, and fall according to the perfection of their adaptation to surrounding conditions, and analogy also tends to overthrow any idea of permanence or fixity in animal species. Thus species becoming evolved beyond a certain point either rapidly degenerate or become extinct, according to the circumstances of their environment. Such then is the doctrine of the scientific philosopher of 1905 A.D., and it is difficult to see how it differs essentially from that propounded by Heraclitus in 500 B.C. Darwin is certainly as lucid as Heraclitus was obscure, and Darwin is exact where Heraclitus was mysterious. But after all, we come back to the *panta rei* as the be-all and end-all of the manner of the world; matter organic and inorganic, existing only in transition; the universe in a state of flux. The ultimate essence of all things which Heraclitus looked upon as "fire," we, after two and a half thousand years, designate "electricity," and it may as well be admitted that we know about as little of the one as he did of the other. What we term the struggle for existence and the survival of the fittest he spoke of as contradiction and strife constituting the essence of existence. Latter-day scientific pronouncements read more like revised editions of the *peri phudeos* of the old Ephesian philosopher, than as dazzling original creations by modern geniuses.

Notes on Current Topics.

Happiness as an Economic Item.

THE commercial and economic value of happiness has been the subject of discussion in the *Business Magazine* by the eminent psychologist, Professor Walter Dill Scott, of North Western University. The writer tells us that he has found by repeated laboratory tests that a man's ability to put forth effort is dependent upon many

factors other than his general physical condition. Some athletes have been found to double their strength under coaching. When a man is trying his best he still may not be putting forth more than half his possible strength. Another powerful modifying factor in the availability of physical strength is "the general condition of the mind of the person tested." Professor Scott finds that every element of pain reduces the strength, and every element of pleasure increases it. Factory hands can produce more in a day under pleasant conditions than when under unpleasant ones. Pain, the writer tells us, lowers the vitality, affecting, as it does, the functional activity of the heart and lungs, and thus of the whole circulation; and, consequently, of the nutrition of the whole body which depends thereon. "These things go far to explain the sudden demoralisation of a football team which for a time has been the equal of its successful opponent." Of course, he might have added examples from the various occupations of ordinary life, as well as from the field of sport. It is universal experience that happiness stimulates both mind and muscle to keener and more rapid and more effective activity. It originates new devices, mechanically; and new diplomatic schemes, politically; and assuredly promotes cordially united effort towards the attainment of desirable consummations. In the exercise of the available powers of the office as well as of the team, of the mechanic as well as of the diplomatist, in the hall of council and on the field of battle, the most optimistic spirit accomplishes the best results.

Hospital Sunday Fund.

It is with peculiar satisfaction that we read that the Hospital Sunday Fund have decided to make a move in the matter of the overcrowding of the out-patients' departments of the London hospitals. This glaring abuse of the hospital funds has been increasing in magnitude every year, encouraged unfortunately by many hospital managers, who like to boast of the extent of their work by referring to the number of cases treated, irrespective of whether the patients were or were not fit subjects for charitable relief. The Hospital Sunday Fund have informed the secretaries of the eighty London hospitals that have out-patient departments that the increase in the number of patients is detrimental to the welfare of both hospitals and patients. Many suffer only from trivial complaints, and they only burden the funds and take up the time of the staff which should be devoted to the more serious cases. The Sunday Fund do no more than invite the opinions of the hospital boards on the subject, and, if these agree with their own, any suggestions for a remedy. They would be glad of an answer before the end of the financial year. Now the Sunday, though only one of the Funds, are a powerful and influential body, and what is more to the immediate point, are in possession of an

income of £75,000, which they can distribute at will. No hospital can, therefore, afford to disregard their representations, and it may be well that this step tentatively taken will lead to that reform in the out-patient departments which has been so long and urgently pressed for by medical men. No doubt the Fund will encounter difficulties in the way, but we hope they will have the courage of their opinions, and if they succeed in remedying the abuses they are preparing to tackle, they will deserve the congratulations of the profession.

Linnæus and His Gout.

THE student of the history of Botany, if a genuine devotee—as every student of that fascinating science is so likely to become—values Sweden chiefly as the land of Linnæus. And one of the items of the folk-lore medicine of that country was largely used by the immortal botanist on his own person. He tells us that he was cured of a violently acute attack of gout by eating wood-strawberries. Ever afterwards, it is almost superfluous to add, he consumed during the season as many as his digestive organs could dispose of. Like every genius, he was greatly influenced by the agencies of the emotions. He had on one occasion been tightly gripped in the vice-like embrace of gout, and was disposed of in the regulation costume of chairs, cushions, pads, and bandages. A sympathetic Providence just then sent a former pupil home from Canada loaded with new plants, with which he at once hastened to his almost adored master. When he entered the room where the latter sat groaning, and laid his offering before him, the overjoyed enthusiast at once stood up, and continued to walk about while examining the valued specimens! Readers will, of course, remember how the "strawberry cure" of gout was boomed some five or six years ago as a *new* clinical discovery. Not an unprecedented item in the history of invention by any means!

The C.E.T.S. and its Methods.

ANY comments that we may make on the methods of the Church of England Temperance Society will not be taken to indicate a spirit of hostility to a society which in its aims, and hitherto in most of its methods, has deserved the support of all social reformers. There is no class in the community that of late years has done more to draw attention to the evils of alcohol than the medical profession, and if any evidence were needed as to current opinion on the subject we might mention the recent petition forwarded to the President of the Board of Education in favour of teaching hygiene and temperance in elementary schools, a petition which was got up by leaders of the medical profession and signed by 15,000 practitioners. But we see from an appeal in the daily Press that the Church of England Temperance Society, through its branch at Norwich, has embarked on a system of treatment by private

methods, and that it is now touting for patients to fill its "home." Anything more degrading to the Society or insulting to the profession it is difficult to conceive. The Society, before making this fatal mistake in policy, would have done well to take into their confidence approved leaders of medical thought, and to have been guided by their advice as to the method to be pursued. The result would have been a foregone conclusion. Secret treatments and secret remedies there have been and are without number, to cure alcoholism and all the diseases under the sun; but they have only a long record of failure, generally associated with heartless frauds, to show. Medicine is a catholic and honest profession, and has ever shown itself as willing to approve what is good and sound, as to reject the worthless and underhand. Mr. Phillips, who signs the letter of appeal, will have only himself to thank if he finds himself in the future in a very uncomfortable position with regard to this "method of treatment."

The Vicar as Healer.

CERTAIN of the less well-informed members of the Church still seem to hanker after the ancient prerogative of the Apostles in the healing of the sick, though it may be gratefully acknowledged that the bulk of churchmen and of other religious sects recognise that the function of curing the body is best performed by those who have acquired some knowledge of disease and of remedies. The modern clergyman, too, must have reason to be thankful that the task of attendance on sick people is performed by others than himself, as his own duties are sufficiently onerous and exacting without the labour of watching medically over the sick of his flock being added to them. Incidentally, too, it may be to the advantage of the patient that the present arrangement prevails. With the Vicar of Brigstock, however, it would appear to be otherwise than with most of his brethren. It seems that the countryside in and about Kettering has been thrown into a state of apprehension by the occurrence at Irthlingborough of several cases of "spotted fever," as the newspapers delight to call cerebro-spinal meningitis, and their alarm has been justified to a certain extent by a crop of cases appearing in a farmhouse at a village called Grafton Underwood. Following on this outbreak came a case of illness in Brigstock which interested the Vicar greatly, so much so indeed that he appears to have assumed the rôle not only of physician but of medical officer of health, for, with a boldness born of ignorance, he is reported in the *Morning Leader* of August 15th to have communicated with the Local Government Board. A happy ending came about by the patient in question recovering, though through whose instrumentality the report does not state specifically. The Vicar is naturally elated, and goes about publicly boasting that he has cured the sufferer of cerebro-spinal meningitis. The paper naïvely adds: "But for the flat denial

of the medical authorities that the case was one of spotted fever, the close proximity of the two places would have afforded a likely explanation of the present outbreak." The Vicar, at all events, will now be free to resume his own avocations.

Death of an Amœba.

THE amœba loomed largely over the mental horizon of most of us in the days of our physiological probation. And there has always been attached thereto an interest of mystery unsolved. From one point of view, at least, this microscopic specimen of animated nature seemed to possess a definite physical claim to immortality. Multiplying its own image by a simple process of splitting itself into two halves, it thus continues its career through time and space in such a way as to leave it quite impossible to say where the line of definition between parent and offspring can be drawn with anything like logical precision. Mr. Edwin Linton has contributed to *Science* what we believe to be a pioneer observation—"The Death of an Amœba," in one of its parts. He had been observing one, which seemed rather more highly charged than usual with granules, when on the point of undergoing the process of procreation by fission. It split, in an approximately normal fashion, but one of the resulting parts possessed less protoplasm and more granules than the other. Then the more protoplasmic half moved quietly away to live its blameless life, but the more granular one began to show symptoms of internal anxiety. It assumed an irregularly spherical shape; it gave the observer the idea of appearing as if the contents were too much for the skin, and—in another moment, all that was left was a cluster of granules without connecting material, and without any sign of animation whatever. The entire process occupied about eight minutes. The observation is an epoch-making one; it is a primary record, and goes to show that the immortality of the amœba cannot henceforward be regarded as an essential article of biological faith.

Suicide after Operation.

AN incident is reported in the *Odessa Novosti*, which, if true, is full of pathos and interest for medical men. It appears that a Dr. C. Polyankoff was driving past a farm when a poor woman ran out of a cottage and begged him to see her child, who was very ill. The doctor did so, and after examining the patient came to the conclusion that he had diphtheria, and advised that he should be removed to the town hospital. The parents, who seem to have been deeply attached to the child, refused to part with him; and Dr. Polyankoff was compelled to do the best he could for him in the rude cottage. Calling next day, he found that it was necessary to perform an operation—presumably tracheotomy—and single-handed he essayed to carry it out. Something, however, went wrong during its performance, and though he gave up his engagements and remained with the child for some time he saw

that it was impossible to save the patient's life. This unhappy occurrence so much affected his mind that he burst into tears, and reproached himself with being a murderer. He then hastily wrote a note, and putting it under the ink-bottle, asked the mother for a drink of water. No sooner had she left the room to fetch it than the report of a revolver was heard, and on hurrying back she found Dr. Polyankoff dead with a bullet-wound in his temple. The note ran as follows: "Pardon a young doctor his involuntary error, by which he has deprived you of your child. I have expiated my crime. May my death serve to comfort you for the grief that has befallen you." It is sad to think of a young fellow of such obviously good parts destroying his life in consequence of an error of judgment.

The Teaching of Sexology.

In a contribution to the *Pacific Medical Journal* of July, 1905, which bears the title of "The Medico-Legal Consideration of Perverts and Inverts," Dr. R. W. Shufeldt (retired Major, U.S.A. Medical Department) pleads strongly for the desirability of the recognition and systematic teaching of the science of sexology. He refers, forcibly and feelingly, to "the case of the unhappy Miss Ida C. Craddock, a teacher in sexology, who was driven to suicide through the outrageous injustice of the law courts, and the persistent prosecution of the public censor of obscene literature." And this impression was originally stamped on the writer's mind by an indelible personal experience. Of this he tells us that: "Never was I so discourteously treated in the witness-chair in my life, where I sat as an expert in that lady's case, as I was by the senior or presiding judge in that farce of a trial. It was astounding and distressing to observe how utterly ignorant the judges were of the nature of the person on trial or of anything else that pertained to the subject." Major Shufeldt scouts the idea that the definitely clear scientific teaching of sexology would tend to the promotion of "vice." He tells all advocates of this view that they seem to be totally ignorant of the fact that at any time in the life of one who is a sufferer from any pronounced form of sexual abnormality, the abnormality is not communicable to others, either through infection or contagion. Further, that those who are psychically and sexually sound, and so constituted that they will remain so throughout life, are in no danger of being rendered otherwise, either by viewing art works of any description, or reading books on sex or sexual diseases—much less by associating with sexual perverts. While on our own part strongly disposed to draw the line—very sharply and tightly—at all unnecessary "association," from the fact that we are strong believers in the power, for culture and development, of the factors of idleness, "suggestion," and opportunity, we in the main agree with his view, and believe that in the case of healthy

minds the seeds of "vice" fail to take life-supporting root when they fall on the rocky soil of moral sanity. And we are also strongly of the opinion that more definitely systematic teaching would tend to prune morbid curiosity, while it would most assuredly cut the ground from beneath the feet of the very numerous quacks who now depend on it for a—very substantial—source of nutrition.

Dr. Freyberger as an "Obvious" Expert.

MR. JOHN TROUTBECK, his Majesty's Coroner for Westminster, continues his ostentatious flouting of the main body of the medical profession by employing a so-called "expert" to give medical evidence. Recently the gentleman in question, Dr. Freyberger, has appeared as a witness in two asylum cases, in both of which a patient died from terrible injuries. As a matter of fact it does not need the self-assumed expertness and special training of a Freyberger to say when a person has received a mortal injury in the shape of a ruptured heart or liver. It may be noted that newspaper reporters appear to follow Dr. Freyberger's evidence with the utmost keenness, inasmuch as the public is being constantly regaled with choice bits of more or less medical knowledge hailing from that quarter. Such publicity, however, must perhaps be regarded as an unfortunate accident, inseparable from the office of Mr. Troutbeck and of his somewhat hybrid official, for we believe that neither Mr. Troutbeck nor the London County Council has any legal ground for appointing a special pathologist. So far as we can gather, Dr. Freyberger's chief justification for the post appears to be in furnishing newspaper reporters with ponderous statements of the obvious. Not long ago, for instance, a short lecture on the elastic function of the ribs in the protection of internal viscera was delivered in Court. We venture to assert that the ratepayers of Westminster would find it far less costly and more to their interest in other ways to insist upon the employment of general practitioners at inquests.

A Liquozone Testimonial.

IT will be within the recollection of readers that a Coroner's Court inquiry recently attributed a death to frequent doses of a proprietary preparation sold under the name of "Liquozone." It was shown that sulphurous acid was an active ingredient of the preparation, and that death was due to the irritant action of that drug. An accident of that kind, it might readily be supposed, would kill the patent medicine that killed the patient. The proprietors, however, evidently do not share that opinion, for they have started on a new phase of activity that has attracted the attention of the editor of *Truth*. Among new Liquozone testimonials is one by Mr. S. Rideal, D.Sc.Lond., F.I.C., who states that a 5 per cent. solution of sulphurous acid kills cultures of *bacillus typhosus* in five minutes, whereas sulphuric acid of similar strength takes a quarter of an hour. He states

elsewhere that Liquozone is a perfectly safe preparation for adults (it was a child that was the subject of the inquest). This statement as to the innocuousness of the stuff we regard as absolutely misleading and dangerous. It is so serious a matter that, in our opinion, it demands the attention of the Senate of the University of London, from whom Mr. Rideal has obtained his degree in science. After all said and done, it is open for the proprietors of Liquozone to point out that evidence favourable to their preparation was given at the inquest by a well-known physician and lecturer in forensic medicine. Another testimonial has been furnished by Gordon Stables, M.D., late R.N.

Creator Recreatus.

THE year of grace 1905 threatens to produce such a crop of spontaneous generators as is likely to be a serious menace to the public peace of mind. No sooner have the remarkable discoveries of Mr. Butler Burke ceased to be (a short) nine days' wonder, than we are faced with a new creator of life, Dr. Charles W. Littlefield. In the pages of *Harper's Weekly* he tells a thrilling story. Recognising that living beings must have originated ultimately from inorganic substances under certain primeval conditions, he set himself to reproduce as far as possible the *milieu* of the creation, and having provided all the accessories needful for the birth of life, sat down to watch. Twelve miniature oceans were represented by twelve prosaic tumblers of water, and into each were introduced the mineral compounds essential to the composition of animal and vegetable tissue. Next he added a drachm of carbon bisulphide to each of the miniature oceans—perhaps by way of smelling out any recalcitrant mermaids—and left the tumblers uncovered and exposed to a regular temperature of 75° to 80° Fahrenheit, each ocean being filled up with boiled water to supply the loss caused by evaporation. Here, then, we have all the materials of creation ready to hand, except perhaps that no darkness was provided to brood over the face of the deep tumblers. The accoucheur did not have long to wait before the portents of the coming birth appeared in the shape of crystals resembling "well-proportioned vegetation" in drops of water removed from the oceans and evaporated on glass-slides. These crystals were then set on plates, and surrounded by a moist atmosphere at between 75° and 80° Fahrenheit, when in twenty-eight days—hey, presto!—a number of microscopic plant and animal cells were found growing on the plate. As Charles Bertram would say: "Isn't it wonderful?" The extraordinary thing is that scientific men should have blundered along all these years without having thought of this simple plan of re-enacting the creation: if they had only studied Hamlet, they might have discovered the value of the method long ago. We now confidently await the resignation of the Archbishop of Canterbury, the disestablishment of the Church, and unqualified apologies from all leaders of religious thought.

Abuse of Sanitary Powers.

It is possible to have too much of a good thing, even of compulsory sanitation. Perhaps it might be well to say at once that superfluous or ill-grounded sanitation is alone meant. Thus amended the statement applies to the ridiculous counsels of perfection that are constantly being thrust upon long-suffering householders by unwise, over-zealous or corrupt sanitary authorities. In some notorious cases that have come to light the hapless ratepayer has been simply "bled white" by sanitary inspectors in league with builders and engineers. It is extremely hard to get at blackmailing of that sort, and the chief safeguard lies in the careful supervision of all subordinate reports as to sanitary defects submitted to the Medical Officer of Health, and by him to his local authority. A contemporary has recently given some glaring instances of persons living in the country who have been called upon, under various pains and penalties, to lay on the local water supply, in spite of the fact of their possessing excellent wells of their own. It cannot be too widely known that the local authorities have no power to act unless they can prove by bacteriological analysis or otherwise that the existing supply is impure. In other words, the order to adopt the public supply, unless supported by specific evidence of impurity, is grossly illegal, and can be resisted by the owner. In such cases the authorities appear to reckon on the ignorance of the man in the street of his own rights in relation to sanitary legislation.

Death caused by Yew Leaves.

THE poisonous effects of yew leaves upon cattle are well known, and many instances of fatalities of the kind are on record. Human poisoning is practically unknown, chiefly because mankind is not given to indulging in food of that sort. A few days ago, however, an inmate of St. Andrew's Lunatic Asylum, Northampton, consumed a quantity of leaves unperceived by the attendants. He subsequently died, and at the inquest the sensible suggestion was made by the jury that all yew trees in the asylum grounds should be cut down. The occurrence is of interest. Doubtless instances of a similar kind could be discovered, and we should be glad to hear of any that may be known to our readers.

PERSONAL.

THE KING and Queen paid an unexpected visit to Ryde on Wednesday, the 9th inst., and inspected the Royal Isle of Wight County Hospital.

THE foundation-stone of a new isolation hospital at Preston was laid by Dr. Brown, chairman of the Health Committee, on August 10th. It is expected to cost £20,000, and will be provided with two pavilions for scarlet fever, one for diphtheria, and one for typhoid fever patients. There are to be 56 beds.

MR. A. CAMERON CORBETT, M.P., has notified the Lord Provost that he has agreed to purchase a part of Ardkingloss estate, and intends handing it over to the Glasgow Corporation. The extent of the land in

question is 9,000 acres, and is finely situated between Loch Long and Loch Goil.

THE Lord Chief Justice (Lord Alverstone), who has had a cottage hospital built at Shanklin, Isle of Wight, in memory of his only son, the late Hon. Arthur Webster, will formally open the building on Wednesday, September 20th next.

UNDER the will of the late Mr. Godfrey Ermen, Manchester receives a donation of £12,000 to the Children's Hospital. It is to be applied to providing a new dispensary and out-patients' department and will cover the cost, leaving the funds contributed by various helpers available for other objects of the appeal.

MISS HONAN has presented a new operating theatre to the North Charitable Infirmary, Cork.

SIR FREDERICK TREVES, G.C.V.O., will take the chair at the annual dinner of the London Hospital Medical College, on the opening day of the Winter Session, October 2nd.

SIR JAMES CRICHTON-BROWNE, LL.D., F.R.S., will deliver the inaugural address at the commencement of the Winter Session at Charing Cross Hospital Medical School.

THE London Homœopathic Hospital has just received a legacy of £250 bequeathed to it by the late Miss C. M. Petter, of Bournemouth.

LAST week a donation of 100 francs was sent from the medical officers of the French Fleet to the funds of the Royal Portsmouth Hospital.

DR. W. H. CLEMENTS, District Commissioner and Government Medical Officer of the Caicos Islands, has been appointed District Commissioner and Assistant Colonial Surgeon in the Toledo District of British Honduras.

Special Correspondence.

[FROM OUR OWN CORRESPONDENT.
BELFAST.

INFANT MORTALITY IN BELFAST. The Medical Inspector of the Local Government Board attended a meeting of the Public Health Committee of the Corporation last week, to confer on the subject of the excessively high infant mortality now prevailing in the city. He suggested to the Committee the desirability of issuing instructions regarding the feeding of infants, as was done on a former occasion with good results when the death-rate from diarrhoea and similar diseases was unwarrantably high. The Committee has adopted the suggestion. They have also taken steps to procure information regarding the deaths of children under five years of age, and one of the lady sanitary inspectors has been sent to inquire concerning the circumstances. She reports that most of the children are nursed out, that is, the mothers work out and leave the children with some one who is willing to take charge of them for a small consideration. They were nearly all bottled, and seemed to have been ailing from birth. In only one case did they admit having used condensed milk.

LONDONDERRY ASYLUM.—The report presented last week shows that during the past year there has been a decrease of one on the male side, and an increase of 14 on the female side, the total number of patients being now 512. The asylum is overcrowded by 116 patients.

DEATH OF DR. McMORDIE, OMAGH.—Dr. David McMordie, a young medical man of great promise, died suddenly at Omagh on August 11th. He had suffered from two brief attacks of meningitis during the summer, but they seemed to have passed off entirely, and to have left no trace behind. Apparently, however, they were connected with some deep-seated trouble in the brain, which caused a sudden collapse. He had assisted at some operations at the County Tyrone

Hospital on Thursday, and had gone to bed apparently in good health, but was found unconscious in the morning and died the same evening. Dr. McMordie was one of the most brilliant students of his time in the Royal University and in Queen's College, Belfast, and after graduation he acted as demonstrator of anatomy in the latter institution for some time. After a trip to India, and some experience as a resident medical officer in a large English hospital, he settled at Omagh two years ago, and soon made many friends. When at college he was deeply interested in the Literary and Scientific Society, and in the Students' Christian Union, and was elected President of the Medical Students' Association. His many fellow-students, now scattered over the world, will hear of his early death with very real and deep regret.

Correspondence.

THE PHYSIOLOGICAL BASIS OF NATIONAL STABILITY.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—The address of Dr. Carpenter on the "High Infantile Mortality Rate" and the letter signed by Henry Sewill on the "Physiological Basis of National Stability," which appeared in your last impression afford interesting reading when compared and assimilated. On the one hand we are informed that 75 per cent. of modern mothers are capable of feeding their babes with the food Nature has provided, but that scarcely any among the upper classes yield to the maternal instinct, allowing them to be fed (or the reverse) by artificial foods administered by other hands, the result being a high preventable mortality. Then we see the original bogey presenting himself through the mist, "Children are few because parents are skilled in the art of preventing conception and deliberately practise it," and thus the diminishing population question is re-introduced with considerable force of fact and argument: the births when they do occur being rendered nugatory by parental neglect, and kept down on the other hand by the selfishness of those whose higher aspiration is subordinated to the desire for a life of ease. That the population of France has remained stagnant for many years through the combined conditions referred to is a fact which cannot be denied. That the population of her neighbour Germany has increased and is increasing enormously is equally patent; the physiological basis of the one being gradually undermined by the more virile prowess of the other naturally gives point to the question raised by Mr. Sewill, Will not the stronger nation eventually absorb the weaker? And as the birth-rate in our own country is diminishing and a high infant mortality rate prevails, are we too not in danger of succumbing to the evil we deplore in our neighbours on the other side of the English Channel? Unfortunately the birth-rate of the morally and physically unfit does not diminish, and this, in my mind, constitutes the greater national danger.

I am, Sir, yours truly,

AN URBAN PRACTITIONER.

"THE PASSING OF THE MEDICAL PRACTITIONER."

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Your excellent leader of August 9th clearly sets forth the case of the average medical practitioner from the worldly point of view—the view of the profession as a wage-earning occupation—the view unfortunately which is necessarily most forcibly and constantly presented to the bulk of its votaries, but you have not mentioned the important fact that there are too many of us. There are not enough patients to go round. When we are equally divided there is not a living to be gained by any one; if, as usually is the case, a few obtain the bulk of practice, the rest are left without the chance of earning a livelihood. I live in a first-class "residential" district within 50

miles of London. The inhabitants all told number about 25,000, and there is at least one doctor to every five hundred. Perhaps six are earning fair incomes. Of the rest, some six or eight manage to get along without too much display of the shabby over the genteel. How the rest contrive to live unless they possess private resources is a mystery. Too many men enter the profession; of these a great number have not the personal qualifications which go to the making of a practitioner who can command success with the public. Success as a practitioner, a family doctor, very largely depends upon the amount of true sympathy with human weakness and human suffering with which he is inspired, and such sympathy cannot be imitated completely by the most consummate hypocrite. Albeit it may be augmented by cultivation in those who possess its germs, it is only such a sympathetic nature that can devote his patience and highest skill to the amelioration of the petty ailments with which he is mostly called upon to deal. It is only one who has such a will who can gain the amount of esteem from his patients which places him in the position of friend and confidential adviser in every question within his province. Medicine from the worldly point of view may not be the worst of professions, but it is certainly the worst when pursued as a trade. The men who take the lowest qualifying degrees and enter practice, not only without adequate experience, but without the professional spirit, the love of their work and the sympathetic qualities which I have referred to, are doomed to failure. It is a pity men do not as a rule recognise this until too late; they linger in many false positions until middle age slips by, until it becomes impossible to extricate themselves from the position of complete failure in which too often in the end they are landed. These failures can be prevented only by putting before intending candidates a full and clear statement of the difficulties which environ the medical life; and seeing how pathetic and pitiable becomes the fate of many of our brethren who have lacked this essential preliminary knowledge, it is deeply to be regretted that the full unvarnished truth is not impressed upon every student within the earliest suitable period of his novitiate.

I am, Sir, yours truly,
AN OBSCURE PRACTITIONER.

Literature.

ALGIERS IN WINTER. (a)

"FROM Cloud to Sunshine" is the title of a little book from the pen of Dr. Alfred S. Gubb, who was formerly on the editorial staff of this journal, but now in resident practice in Algiers during winter, and Aix-les-Bains in the spring and summer months. The booklet is, as its sub-title suggests, a guide to "Algiers as a winter resort," and as such will be found useful to English practitioners having patients whose health necessitates hibernation in more favoured climes than home. To the information regarding the climatic advantages of Algiers and their therapeutic bearings, are added many hints and suggestions on the selection of villas, lodgings, and hotels; the engagement of attendants and the like, which should prove of inestimable value to intending visitors. These are further supplemented by instructions how to reach Algiers, the various sea and land routes, times of departure and arrival, costs of transit, &c., which will save them the trouble and anxiety of hunting up such necessary information for themselves. Formerly hotel accommodation was scanty, uncomfortable, and excessively dear, but the author tells us this is now a thing of the past, excellently managed hotels having been provided to suit all purses, and attractions studied in various ways for those who visit Algiers either for health, pleasure, or both.

(a) "From Cloud to Sunshine." By Alfred S. Gubb, M.D., M.R.C.S., D.P.H. London: 1 ailliere, Tindall and Cox. 1905.

Obituary.

GRIFFITH WILLIAMS ROBERTS, L.R.C.P.Ed.,
L.F.P.S.Gl., M.D.St. And.

We regret to announce the death on Thursday of Dr. Griffith Williams Roberts, medical officer for the borough of Denbigh. Dr. Roberts had been in ill-health for some time. The Town Council was in session at the time, and had just appointed Dr. Roberts' son as deputy medical officer, when the news was received that the father had passed away. Dr. Roberts was 64 years of age, and was appointed medical officer in 1879. He was the centre of a wide circle of friends and patients by whom he will be mourned. He was educated at Edinburgh, and took the qualifications of L.R.C.P. in 1864 and M.D. St. And. in 1882.

Medical News.

A Nothnagel Scholarship.

THE Senate of Vienna University has decided to devote £1,000 to the purpose of establishing a scholarship in memory of the late Professor Nothnagel. The prize is to be awarded to the essay which gives the best answers to medical problems proposed yearly by the Senate. In the case of no essay being considered worthy of the prize, the money is to be laid out with a view to encourage original research on diseases of the intestines.

Red Cross Society of Japan.

THE Red Cross Society of Japan is, by its creation, the last of Red Cross societies, but it is by far the first and foremost of these societies by its splendid organisation, its wealth, and its power for good. The Japanese Red Cross Society had recently 920,000 members; its funds in hand amounted before the war to £794,000; and it possessed an annual income of £231,000.

Prize Offered for a Cancer Cure.

THE Brazilian Chamber of Commerce, we learn on the authority of the *Pall Mall Gazette*, has devoted the handsome sum of £400,000 as a prize to be given to the scientist who shall discover a really enduring method for the cure of cancer. An international committee is to be formed, consisting of two members of the Medical Academy in Rio Janeiro, and of four eminent pathologists chosen from London, Paris, and Rome. These six gentlemen will act as the jury in the case of awarding the prize.

PASS LISTS.

Society of Apothecaries in London, August, 1905.

THE following candidates have passed in:—

Surgery.—H. J. Aldous (Section II.), C. W. S. Boggs (Section II.), H. A. Browning (Sections I. and II.), G. M. Seagrove (Section II.).

Medicine.—F. D. Addis, C. W. S. Boggs (Section II.), J. H. Harrison (Section II.), F. J. F. Jones (Section I.), E. B. Miles, W. G. O'Malley (Sections I. and II.), W. V. Pegler (Section II.), N. A. Stutterheim (Sections I. and II.), A. Whitby.

Forensic Medicine.—E. Moir, N. A. Stutterheim.

Midwifery.—E. Moir, A. F. Palmer, F. C. H. Powell.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—Messrs. H. J. Aldous, C. W. S. Boggs, H. A. Browning, E. B. Miles, and N. A. Stutterheim.

As a commentary on the vast amount of temperance agitation that has been carried on in Stepney during the past few years 96 deaths were reported last year as attributable to drink.

DR. H. KENWOOD, Medical Officer of Health for Stoke Newington, says in his annual report that "If the death-rate among calves were only one-half of that which prevails amongst infants, the British farmer would before very long have to entirely give up the business of rearing cattle."

Notices to Correspondents, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, ut as evidence of identity.

M. O. H. (Grimsby).—It is estimated that 218,000 children in England and Wales are paupers and brought up at the cost of the ratepayers. Nearly half of all children born in the two countries die in the first year of life. Sir Francis Galton delivered at the Anthropological Institute an able lecture on "The Possible Improvement of the Human Breed under the Existing Conditions of Law and Sentiment."

PATERFAMILIAS.—At the smaller institution, the student has probably a better chance of acquiring the practical knowledge of his profession. At the hospital to which you refer, every student is required to serve as Out-patients' Dresser for a period of four months, and as In-patients' Dresser for a further period of four months; and while holding the former appointment is required to act as Clinical Clerk in the Surgical Wards under the direction of the Surgical Registrar.

DR. H. (Bangor).—(1) Efforts to influence cancer growth by immune (cytolytic) sera or to interpret the more minute cell changes accompanying different Phases of growth have not yet led to any definite conclusions. (2) Specimens of carcinoma and sarcoma have now been obtained for the first time from native races inhabiting various tropical regions.

DENTAL SURGEON.—The first important work on the subject of dentigerous cysts was published in 1872 by Magitot, the well known Paris dentist.

DR. L. (Burton).—In every case of death in a lunatic asylum the authorities are required to forward a report to the coroner. Upon receipt it is within the province of the latter to make any further inquiries.

M. O. H.—The paper you refer to on the evils of kissing is by Dr. Charles Féré and appeared in the *Revue de Médecine*. He includes syphilis, tuberculosis, diphtheria, exanthematous fevers and various forms of skin eruption. The injunction to friends visiting patients in consumptive hospitals not to kiss seems based on sound common-sense.

JUSTICE.—You could not do better than join the London and Counties Medical Protection Society. Last year it dealt with 13 claims for damages for alleged negligence and most of these were proved unjust. Also 33 cases of libel or slander were met successfully.

NAVAL SURGEON.—There is a handy little volume, "The Ship Surgeon's Pocket Book," 2s. 6d., published by Baillière, Tindall & Co which ought to meet all your requirements. It is written by Mr. W. E. Dawson, Admiralty Surgeon.

RÖNTGEN.—The Russian Institute of Experimental Medicine has announced a prize, value £100, for the best treatise on Radium in skin diseases and particularly cancer. The award will be made January 14th, 1908.

A LONDON Surgeon who recently wanted to send some cases to a medical conference to illustrate a paper on cleft palate, wrote to the railway company asking them to provide for the same. On the date appointed a furniture van came up to his door "to fetch the 30 cases." The idea of "cases" otherwise than wooden did not seem to have occurred to them.

T. WILSON.—The gentleman referred to was a manufacturing chemist, not a medical man as has been generally supposed. His doctorate was LL.D. *Honoris Causa*.

PROVINCIAL SURGEON.—The translation by Dr. Foy, which appears in another column of our present issue of service under the Red Cross, during the war in the East will supply you with the information you seek.

CATGUT.—The origin of the term is obscure, none of the various so-called explanations are satisfactory in any case. We can reply to your question definitely as to its manufacture: the ligatures used in surgical practice are made from the intestines of sheep, not from those of the domestic animal whose name it bears.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, AUGUST 23rd.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—4.15 p.m. Dr. Russell: Medical Cases.

THURSDAY, AUGUST 24th.

POST-GRADUATE COLLEGE West London Hospital, Hammersmith Road, W.).—5 p.m. Dr. Davis: Tonsillitis and its Treatment.

FRIDAY, AUGUST 25th.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—5 p.m. Mr. Paget: Surgical Cases.

Vacancies.

Noble's Isle of Man Hospital and Dispensary, Douglas, Isle of Man.—Resident House Surgeon. Salary £90 per annum, with board and washing. Applications to Richd. D. Gelling, Honorary Secretary, St. George's Chambers, Athol Street, Douglas, Isle of Man.

Essex and Colchester General Hospital.—House Surgeon, Salary £100 per annum, with board, washing and residence in the Hospital. Applications to Alfred G. Buck, Secretary, The Hospital, Colchester.

City of Liverpool Infectious Diseases Hospitals.—Assistant Resident Medical Officer. Salary £120 per annum, together with washing, and lodging at the Hospital. Applications to the Town Clerk, Municipal Offices, Liverpool.

The Municipality of the Town of Singapore, Straits Settlements.—Assistant Municipal Health Officer. Salary £400 per annum. Applications to C. C. Lindsay, Esq., M.Inst.C.E., 180 Hope Street, Glasgow.

Kent County Ophthalmic Hospital, Maidstone.—House Surgeon. Salary £100 per annum, with board, to reside in the Hospital. Applications to the Secretary.

East Riding Lunatic Asylum, Beverley.—Second Assistant Medical Officer. Salary £150 per annum, with board, apartments, and washing. Applications to C. W. Hobson, Clerk to the Visiting Committee.

Berkshire Asylum, Wallingford.—Second Assistant Medical Officer. Salary £140 per annum, with board, furnished apartments, attendance, &c. Applications to the Medical Superintendent.

Lanark District Asylum.—Third Assistant Medical Officer. Salary £120 per annum, with fees, &c. Applications to Nell T. Kerr, Medical Superintendent. (See Advt.)

Appointments.

BARCLAY, WILLIAM BOWIE, L.R.C.P., L.R.C.S., L.M. Edin., D.P.H. Vict., Medical Officer of Health of Weymouth.

BOND, FRANK FOURACRE, L.R.C.P. Lond., M.R.C.S. Eng., Medical Officer to the Trowbridge (Wilts) and District Isolation Hospital.

CUNLIFFE, THOMAS VARLEY, M.D., B.S. Lond., M.R.C.S., L.R.C.P. Lond., Assistant Surgeon to the Oldham Infirmary.

KELLEHER, T. A., M.B., B.S. U.I., Certifying Surgeon under the Factory and Workshop Act for the Waterford District of the county of Waterford.

KELLY, W. M.B., C.M. Aberd., Clinical Assistant to the Chelsea Hospital for Women.

MASON, A., M.R.C.S., L.R.C.P. Lond., Certifying Surgeon under the Factory and Workshop Act for the Deal District of the county of Kent.

REES, W. H., M.B., F.R.C.S., Registrar to the Bollingbroke Hospital, Wandsworth Common, S.W.

Births.

FISCHER.—On August 17th, at Edinburgh, the wife of Dr. Fischer, Calro, of a daughter.

FITZGERALD.—On August 13th, at Eglinton Asylum, Dr. Lucia Fitz-Gerald, the wife of Dr. John J. Fitz-Gerald, of a daughter.

KENNEDY.—On August 15th, at 39 Harrington Street, Dublin, the wife of Surgeon Kennedy of a daughter.

PARKINSON.—On August 15th, at 57 Wimpole Street, London, wife of J. Porter Parkinson, M.D., M.R.C.P., of a daughter.

RUSSELL.—On August 17th, at Oaman House, Fortis Green, London, the wife of J. Dill Russell, M.B., B.S. Lond., F.R.C.S. Eng., of a daughter.

WILSON.—On August 16th, at Marden Ash, Ongar, the wife of Geoffrey R. Wilson, M.A., M.B., B.C. Cantab., of a daughter (still-born).

Marriages.

CALEY—GREEN.—On August 17th, at All Saints' Church, East Budleigh, Devon, Henry Albert Caley, M.D., F.R.C.P., of 24 Upper Berkeley Street, London, to Dorothy, second daughter of Rev. W. F. Green, M.A., Vicar of East Budleigh.

ZILWA—SACHS.—On August 12th, at Park Chapel, Camden Town, London, Lucian Arnold Emmanuel de Zilwa, M.B., B.Sc. Lond., of Ceylon, to Charlotte Eleanor (Lena) Sachs, elder daughter of M. S. Sachs, and the late John Sachs, of Chancery Lane and Camden Town, and granddaughter of the late Titus Danks, of Dean Street, Soho.

Deaths.

HESSION.—On August 13th, at Norwich, Brigade Surgeon Thomas Oliver Hession, late Army Medical Department, aged 70.

KILROY.—On August 13th, at Paramé, France, Philip Le Feuvre Kilroy, Lt.-Col. R.A.M.C., of Eastfield, Ryde, I.W., aged 61 years.

PRACTICE.—Wanted to Purchase a small practice, near Dublin. Sea-side preferred. Reply to B. E., care of MEDICAL PRESS AND CIRCULAR, 16 Lincoln Place, Dublin.

The Medical Press and Circular.

OCULAR THERAPEUTICS. (a)

By SYDNEY STEPHENSON, M.B., F.R.C.S.E.

(Continued from Page 185.)

LECTURE IV.

6.—GENERAL REMEDIES.

General Anæsthesia.—Since the introduction of cocaine by Koller in 1884 there has been a growing disinclination among ophthalmic surgeons to operate under general narcosis if it can be avoided. This tendency is reflected in a recent paper by Dr. Otto Meyer, of Breslau, upon removal of the eyeball under combined local anæsthesia, which appeared in the *Klinische Monatsblätter f. Augenheilkunde* for February last. He had undertaken eighty enucleations of the eyeball under the local anæsthesia produced by instillations of cocaine and the injection deeply into the orbit of Schleich's No. 2 solution. The reaction, however, has assuredly gone too far when we find so eminent an author as Professor Haab, of Zurich, practically advocating the abandonment of general anæsthesia in operative eye work. In his recently published *Augen-Operationslehre* (a work that should be in the hands of every ophthalmic student) Professor Haab takes what strikes me as an altogether exaggerated view of the dangers attendant on almost every form of general narcosis. Everyone will of course admit that if an operation on the eye can be done painlessly under local anæsthesia so much the better, on account of the preparation needed, the time consumed, the risks incurred, and the possibility of vomiting. Professor Haab, however, goes much farther, and advises against the induction of general anæsthesia on account of its danger to life. If his views were accepted generally, the present generation would be denied one of the greatest blessings bestowed upon mankind, namely, the possibility of performing the most severe operations without inflicting the least pain upon the patient. It is obvious that a certain percentage mortality is bound to attend the administration of any general anæsthetic, be it chloroform, ether, ethyl chloride, nitrous oxide, or any other. The relatively greater risk attending the first-named agent has rendered its administration by trained anæsthetists rarer than was once the case. The common practice now is to give gas or ethyl chloride at the start, and then ether or chloroform. Accidents will become less numerous as training in the giving of anæsthetics becomes more general. After all, the risk in skilled hands of giving ethyl chloride or gas and ether is a small one, and I seriously question whether the infinitesimal risks thereby incurred justify us in withholding from our patients the boons of general anæsthesia.

In point of fact, a general anæsthetic is almost indispensable in certain operations upon the eye—as, for example, in acute glaucoma and some other

conditions where the parts are so deeply engorged with blood as to be incapable of absorbing the amount of cocaine or holocaine necessary to produce local anæsthesia. In children, again, there are few operations that can be done with comfort to the surgeon or with safety to the patient under cocaine, for in them it is not pain so much as fright that has to be contended against. Until recently chloroform was the favourite anæsthetic, probably because it was generally available and called for no complicated apparatus, like ether, liable, perhaps at a critical moment, to get into the operator's way. Doubtless, chloroform or ether will remain the anæsthetic for such operations as require a period of prolonged unconsciousness. For brief periods of anæsthesia, however, such as suffice for most operations upon the eye, ethyl chloride is the best agent. It is speedy, relatively safe, easy to give, and produces an anæsthesia free from muscular twitchings, so embarrassing to the eye surgeon. Vomiting, in my experience, is generally due to an overdose.

Much of my personal experience, which now extends to upwards of three hundred administrations, has been gained with "kelene," merely an extraordinarily pure form of ethyl chloride. But Duncan and Flockhart's "chloryl anæsthetic" and Hedley's "ethyl chloride" also represent pure products at a cheaper rate. With regard to the apparatus, there are now several good inhalers available, among which may be mentioned the modified Ormsby ether inhaler made by Messrs. Krohne and Sesemann, and the "Simplex" inhaler of Messrs. Duncan and Flockhart. The point to be aimed at in a good apparatus is the complete or almost complete exclusion of atmospheric air. The mask is fitted to the patient's face, 2 c.c. to 6 c.c. of ethyl chloride sprayed into the face-piece, and the apparatus held over the mouth and nose until general anæsthesia is produced, a thing that, as a rule, does not take more than thirty seconds. The unconsciousness from a single dose lasts from one to three minutes—that is, long enough to perform many of the operations of ophthalmic surgery. If necessary, a longer period of anæsthesia may be obtained by giving a second dose of ethyl chloride or by continuing the inhalation with ether or chloroform. Insensibility is shown by snoring respirations, insensitive cornea, flaccid limbs, and in the case of children by absence of muscular response to a sharp nip in some tender portion of the body. With ethyl chloride a patient may be anæsthetised, operated on, and recover within five minutes, an economy of time that will be appreciated by all who have to work in a crowded and busy out-patient department.

ANIMAL ORGANOTHERAPY

Apart from suprarenal extract, which has already

(a) Lectures delivered June, 1905, at the Polyclinic London.

been considered, two animal extracts have been employed in eye work—"didymine" and "optocine." The treatment of exophthalmic goitre by Dr. Moebius's "antithyroidin" (Merck)—i.e., the blood-serum of rams from which the thyroid gland has been removed, with 0.5 per cent. of added carbolic acid—need scarcely be described in this place, although it is clearly of interest to ophthalmic as well as to general surgeons.

Didymine, or testicular substance, has been used internally in locomotor ataxy. Dr. Lloyd Roberts has recently reported several cases of exophthalmic goitre relieved by its administration, one to five four 5-grain tabloids (Burroughs Wellcome and Co.) being administered several times a day. Testicular extract has been put to a curious and out-of-the-way use by Dr. L. Dor (*Recueil des Travaux Xe Congrès international d'Ophthalmologie*, September, 1904), who gave the product to five children in whom rapid growth was associated with symptoms of asthenopia. Growth was retarded, and incidentally asthenopia improved.

Optocine is the name given to a potent extract from the retinae of freshly slaughtered animals. It is administered in various forms of retinal exhaustion—as, for example, in tobacco amblyopia, in retinitis pigmentosa and in myopic choroiditis. The dose is one drachm two or three times a day. Mr. Robert W. Doyno was the first to bring this novel product under the notice of the medical profession, and those interested in the subject are advised to consult his original communications in the *British Medical Journal* of July 25th and September 26th, 1903. In this place I will merely say that it does appear to expedite recovery in tobacco amblyopia, although it is most difficult in that as in other diseases that tend to self-cure to estimate "optocine" at its true value. I have, however, more than once seen sight improve in such cases even when the patient continued to smoke immoderately. As a matter of some slight historical interest it should be pointed out that extracts from various parts of the eye have been employed by Dor in 1897, by Lagrange in 1898, and by Darier in 1900.

SERUMTHERAPY.

Antitoxic sera have been employed in ophthalmology in the treatment of four conditions, viz.:—1. Diphtheria of the conjunctiva; 2. Hypopyon-ulcer of the cornea; 3. Ocular tuberculosis; and 4. Streptococcal and staphylococcal invasions.

1. *Diphtheria of the Conjunctiva*.—Diphtheria of the conjunctiva is tolerably common among young children of the lower classes in London. According to my personal experience, it forms 1.26 per cent. of the eye cases presented for treatment in the ophthalmic department of a children's hospital. It usually occurs in a mild form, much resembling acute muco-purulent ophthalmia, and is doubtless often mistaken for the latter disease. There is, however, membrane upon the conjunctiva, a point that should suffice to distinguish the two affections. Even fatal cases are not unknown in this country. Mr. Percy Flemming has described such a case in an infant of four months; Dr. Bullar had a fatal case in a baby of ten days; and I have myself had two fatal cases in children, aged respectively 11 and 16 months. The treatment, which should be commenced as early as possible, is by the injection of diphtheria antitoxin, the dose of which will depend not upon the age of the child but upon the severity of the disease. Indeed, the serum appears to be productive of nothing but good, no matter in what dose it is injected. "Mixed injections," as they are called, are very common. Thus, among forty-two cases of diphtheria of the conjunctiva published by me a year or so ago, they occurred in no less than 86.04 per cent. Hence, in addition to antitoxin, local antiseptics should be applied to the conjunctiva. Many remedies may be used for this purpose, but, upon the whole, I have found a 15 per cent. solution of argyrol to succeed as well as anything else I have tried.

2. *Hypopyon-Ulcer of the Cornea*.—There is no more fatal disease of the eye than the one usually

termed in England "hypopyon-ulcer," and elsewhere "ulcus serpens corneae." An elderly person, usually of the labouring classes, with unsound lacrymal passages, receives, in the course of his work, some trifling injury to his cornea. The little wound or abrasion, instead of healing promptly as it would do in a healthy subject, becomes infected with pneumococci from the diseased lacrymal passages, pus appears in the anterior chamber, the ulcer spreads, and in the absence of prompt and well-directed treatment, the eye is only too likely to be lost. The usual treatment of the condition includes slitting the canaliculus, in order to give exit to the infectious secretions of the lacrymal sac, and, above all, the application of the galvano-cautery to the aggressive edge of the corneal ulceration. Saemisch's method—that is, opening the anterior chamber by means of an incision including the entire thickness of the ulcer—is practised by many operators, despite the fact that it is often followed by an adhesion between cornea and iris, which later may have disastrous consequences.

Römer, of Wurzburg, has experimented in this condition with a polyvalent serum of high potency, prepared by Merck, of Darmstadt (*von Graefe's Archiv f. Ophthalmologie*, Vol. 54, No. 1., and *Bericht der Ophthalmologischen Gesellschaft, Heidelberg*, 1902 and 1903). The hypopyon-keratitis was produced in rabbits and monkeys by inoculating the cornea with pneumococci, and Römer's series also included clinical cases as met with in man. Cases treated early almost invariably healed well, whilst almost 80 per cent. of successes were obtained even when the condition was advanced. In 95 per cent. of cases of hypopyon-keratitis the pneumococcus is present. In the earlier experiments the serum was injected beneath the skin and the conjunctiva and also applied directly to the corneal ulcer, but, later, Römer discarded the subconjunctival injections. Several Continental observers have now experimented with Römer's pneumococcal serum, and, as usual, there is no unanimity of opinion with regard to its true clinical value. It is, however, agreed that ulcus serpens produced by experimental inoculation does yield in many instances to the serum. Paul, Augstein, and Zur Nedden, who among them treated 32 ordinary cases of hypopyon-keratitis, obtained a cure with the serum in six only. In the remaining cases, amounting to 81 per cent. of the total number, the cautery had to be applied or the Saemisch section performed before the destructive corneal process could be checked. Paul, one of the most recent writers on the subject, goes so far as to say that the pneumococcal serum should be adopted in exceptional cases only, and that commonly preference should be given to surgical measures (*Klin. Monatsblätter f. Augenheilkunde*, January, 1905). Another writer, Oliveres (*La Clinique Ophthalmologique*, June 25th, 1905), has treated three cases of ulcus serpens with Römer's serum, but in every instance had to resort to other measures, especially the subconjunctival injection of mercury cyanide, before he could obtain cure. Finally, from certain observations made by Zeller, *Med. Corresp.—Blatt des Württ. ärztlichen Landesvereins*, September 3rd, 1904), it appears that the use of serum is not always free from danger. For example, in a case mentioned by him the injections are stated to have been followed by myocarditis.

3. *Ocular Tuberculosis*.—The tuberculous diseases of the eye are numerous and important, although not perhaps altogether common. They include tuberculosis of the conjunctiva, iris, choroid, and lacrymal sac. The superficial manifestations can be attacked with the knife, sharp spoon, cautery, or X-rays, but until recently our means of dealing with the deeper lesions were limited indeed. In fact, the management of such affections was on the lines now generally adopted in treating phthisis pulmonalis—that is to say, by living in open air and bright sunshine, by well-cooked and generous diet, and by careful attention to the state of the skin and other emunctories. Now, thanks to serumtherapy, we appear to be reaching

more tangible and solid ground. "Tuberculin T.R." has been employed by von Hippel (*von Graefe's Archiv f. Ophthalmologie*, August 9th, 1904), in the treatment of fourteen cases of ocular tuberculosis, affecting cornea and uveal tract in thirteen cases, conjunctiva in three cases, and sclera in one case. The injections are gradually increased from 1—500 milligramme up to, but never beyond, 1 milligramme of the product, and are made every other day. The temperature is taken at two-hourly intervals, and should it exceed 100.5° F., no increase in the dose of the tuberculin must be made. In serious cases quite six months' treatment is called for. Von Hippel has never met with any bad effect as regards the general health. But a case recently published by Contino (*La Clinica Oculistica*, November-December, 1904), shows that there may be a reverse to the medal. A child of 10 years suffering from a tuberculous ulceration of the conjunctiva was treated by serum, antitoxic and another, with the consequence that the lesion healed in about a month. Five weeks later, however, the child became very ill, and died comatose in a few days from tuberculous meningitis.

I am not disposed to attach undue importance to Contino's observation, because I have seen something of the same kind happen where serum had not been injected. A child, *æt.* 17 months, presented a tuberculous ulceration towards the centre of the free edge of one lower lid. Twenty-one days later, she was found to have double optic papillitis and tubercle of the choroid. She died twenty-five days after the first examination from miliary tuberculosis (*British Medical Journal*, May 3rd, 1902.)

4. *Pyogenic Invasions of the Eye.*—In certain streptococcus invasions of the eye, as occurs in infected wounds, operative or accidental, antistreptococcus serum has been tried. Claiborne and Coburn, however, as the results of their experiments upon rabbits, conclude that it exerts no favourable influence upon the course of these invasions (*Medical News*, August 6th, 1904). The same serum has also been successfully employed by Darier in a case of purulent ophthalmia in a baby associated not with the gonococcus but with streptococci.

7.—GENERAL CONSTITUTIONAL REMEDIES.

Almost every constitutional affection has its correlated eye disease, and he would be indeed a benighted specialist who employed local treatment to the neglect of general remedies. From a purely practical point of view, two affections of general nature stand prominently forward as causes of disease of the eye, *viz.*, syphilis and rheumatism.

1. *Syphilis.*—Syphilis, acquired and inherited, is the commonest constitutional cause of ocular disease. The acquired disorder is responsible for iritis, cyclitis, choroiditis, retinitis, and for some cases of interstitial keratitis, to name a few alone among the so-called "specific" affections of the eye. The inherited disorder is the common and usual course of interstitial keratitis, and also produces choroido-retinitis, and occasionally oculo-motor paralysis.

In the treatment of the several conditions named mercury and potassium iodide are still our sheet-anchors. But during the last few years new and efficacious ways of administering mercury have been widely employed, more especially upon the Continent. These comprise (a) subcutaneous or, rather, intramuscular injection, and (b) intravenous injection, in each case of soluble mercurial salts. The employment of insoluble compounds, as calomel, appears to be attended with considerable danger, and personally I have had no experience of the method.

(a) Intramuscular injections have yielded me some brilliant results in cases, as interstitial keratitis and choroiditis, that refused to yield to the ordinary modes of administration—that is, by the mouth or by inunction. I once employed a solution of corrosive sublimate (1 grain of the salt to 1 drachm of sterilised water; dose, 10 minims twice or thrice a week), which was deeply injected into the gluteal muscles,

after the skin of the buttocks had been carefully cleansed with soft soap, hot water, ether, and a solution of corrosive sublimate in carbolic lotion. There were, however, certain inconveniences. It was sometimes inadvisable to expose the buttocks, especially in the case of an adult member of the opposite sex. Although I never saw suppuration follow injection, yet the formation of a hard and tender lump on a sensitive part of the body, persisting for several days, was not a thing to be particularly desired. Then, the frequent repetition of injections rendered the part hard and indurated. Moreover, gummata may very occasionally appear at the point of injection of the mercurial fluid, either speedily or not until several months or even years have elapsed. Thus, Juliusberg (*Munch. Med. Woch.*, April 14th, 1903), reported three cases in which such gummata appeared nine months, eighteen months, and several years respectively after the injection. A patient of my own, where injections had been made into the biceps of the upper arm, developed a gumma locally in the course of two or three weeks. The points named have led me to employ not corrosive sublimate but a 1 per cent. solution of mercury cyanide. The results were as good as with the other salt, and no painful lump is ever produced at the site of injection. The exposure of the patient, however, is still a disadvantage. I have no experience of sublimin, a 3 per cent. to 4 per cent. solution of which has been recommended for intra-muscular injection (*Therapist*, January 15th, 1904).

(b) The method I now prefer is the intravenous injection of a solution of mercury cyanide in physiological salt solution. The formula is:—Cyanide, 1; sodium chloride, 0.75; boiled distilled water, 100. Dose, 20 to 40 minims in urgent cases daily, and in others twice or thrice a week. The biniodide salt may also be employed according to the formula:—Mercury biniodide, 1; sodium iodide, 2; boiled distilled water, 100. Dose, 20 to 60 drops (1 c.c. to 3c.c.).

The injection may, of course, be made into any accessible vein that is large and prominent enough, but usually the veins at the end of the elbow—the median cephalic and the median basilic—are the most convenient. Occasionally, the veins of the forearm or the cephalic or the basilic of the upper arm are suitable vessels for our purpose.

The parts are exposed, the vein selected, and a fillet is tied rather tightly around the middle of the upper arm. The skin over the arm is next carefully cleansed and sterilised. The vein is then steadied with the operator's thumb, and the needle pushed obliquely through its anterior wall. Penetration will be at once obvious either by blood falling into the syringe (which should, of course, have a glass barrel) or by rising on slightly withdrawing the piston of the instrument. No injection should ever be made until one of these two things has happened, as otherwise the fluid may be forced into the perivenous connective tissue, where it may cause considerable irritation. The contents of the syringe are then slowly pressed into the vein, the fillet having first been removed. Finally, the needle is withdrawn, and the tiny puncture sealed with collodion, or, if it does not leak, left without dressing of any kind. The injection is painless, provided the needle is passed into the vein without bungling. Timid patients may become faint when the first injection is made. Sometimes a curious and indescribable taste in the mouth is complained of a few moments after the operation is completed.

It is important to bear in mind that signs of mercurial intolerance tell mainly upon the intestinal canal and not upon the mouth in these methods of administering the drug. They include colic and diarrhoea. For some few years I have been familiar with another sign of the mercurial action, which, so far as I know, has not yet been described. It consists in the formation of a red crescent at the free border of the nails, and its dimensions, in my experience, afford an excellent guide to the action of the

mercury. It is better seen on the finger nails, since they are thinner than the nails of the toes, and for obvious reasons it is generally much better marked among the upper than the lower classes.

Before leaving the subject I should like to state clearly that I am in no sense an advocate of injections, except in particular and selected cases. There are many specific affections of the eye that can be treated efficiently by the internal administration of mercury with chalk or other familiar preparation of mercury. It is in diseases, the existence of which threatens to destroy sight or which refuse to yield to ordinary methods that we should, I think, inject the remedy. The disadvantages of intravenous injection are that it consumes time, may alarm timid patients, and that it is not always easy, and indeed sometimes impossible, especially in women and children, to find a vein suitable for our purpose. On the other hand, the process is simple, painless, free from danger, speedy in its effects, and presents the advantage that it is carried out by the medical man himself. I have satisfied myself that it is efficacious in many cases of choroiditis, specific and otherwise, upon which the ordinary preparations of mercury failed to procure any effect.

2. *Rheumatism*.—The precise relationship of rheumatism to many diseases of the eye is still unsettled. The word "rheumatic" is a legacy from old times, and is often even nowadays employed to cloak our ignorance of the essential nature of some ocular disorders. At the same time certain diseases of the eye are undoubtedly of rheumatic origin. Of these the best-known is perhaps irido-cyclitis. A few years ago a theory was propounded by Dr. David Walsh that certain skin affections could be accounted for by excretion from the body of various irritants, such as drugs, micro-organisms, and toxins. It occurred to me (*Lancet*, February 29th, 1896) that the explanation, if correct, should apply to organs other than the skin, engaged in the work of excretion. Now almost all the general ailments capable of causing an inflammation of the iris are associated with, if not actually caused by, micro-organisms. That fact will be disputed by none as regards syphilis, gonorrhoea, tubercle, leprosy, influenza, and relapsing fever. If the bacterial origin of rheumatism be admitted, then a common cause of iritis will fall into line with the rarer causes enumerated above, for it must be remembered that the ciliary body secretes the aqueous humour (E. T. Collins). The position might be stated in terms of a syllogism, as follows:—Most inflammations of the iris and ciliary body are dependent upon a constitutional ailment; a majority of these ailments are of bacterial nature; therefore, most forms of irido-cyclitis result from the action of micro-organisms. It was suggested as possible that the immediate cause of these inflammations might be sought in the vicarious glandular excretion of microbes or their products circulating in the blood or other nutrient fluids of the body. Since then Drs. Poynton and Paine have isolated from the lesions of acute rheumatism a minute diplococcus, now very generally accepted as the specific pathogenic agent. Not the least interesting result obtained by those workers has been the experimental production in rabbits of iritis by the injection of a pure culture of their "diplococcus rheumaticus" into the auricular vein of rabbits. The animals died of heart disease, and the causative organisms were found in the cloudy fluid of the anterior chamber of the affected eyes. A culture from that fluid, when injected into another rabbit, gave rise to chronic arthritis (*Ophthalmoscope*, October, 1903). The rheumatic origin of certain cases of irido-cyclitis has therefore been established both theoretically and experimentally. In my own mind, I entertain no doubt that conjunctivitis is rarely and episcleritis commonly due to chronic articular rheumatism.

As to palsy of the ocular muscles and its "rheumatic" origin I am somewhat sceptical. Such

patients, when watched long enough, are not infrequently found to develop serious nervous lesions, more especially insular sclerosis or tabes dorsalis. I may quote briefly the main facts of two such cases, of which the first eventually proved to be an instance of insular sclerosis, and the second was one of tabes dorsalis, presenting some resemblance to a so-called "rheumatic" paresis. *Case No. 1*.—Miss Y——, æt. 24, who gave a history of chronic articular rheumatism, consulted me in February, 1890, on account of a palsy of the left external rectus muscle, of some weeks' duration. The paralysis was assigned to rheumatism, a diagnosis apparently confirmed by the fact that recovery took place in about three weeks under ordinary anti-rheumatic treatment. In the beginning of 1900—that is, ten years later—Miss Y——again came to me, on this occasion with paralysis of the right external rectus muscle. She also presented nystagmoid movements of the eyes, trembling of the legs, exaggerated knee-jerks, ankle clonus, and paræsthetic areas about the lower extremities. There was a history of occasional incontinence of urine, and of unsteadiness in the street. The diagnosis of insular sclerosis then seemed obvious, and it was reasonable to look upon the first attack of ocular palsy ten years before as a premonitory sign of that disease. *Case No. 2*.—Mr. W——, æt. 33, seen May 26th, 1905, complained that he had seen double for two days, and gave a history of a similar attack ten years ago, which lasted for about five weeks. Rheumatic fever at 7 years and "rheumatism and pleurisy" at 13 years of age. Patient subject in damp weather to pains in the arms and legs, and for three months had suffered from pains over the right eye and at the back of the neck. Upon examination, paresis of the right external rectus. Both optic discs, especially the right one, greyish; retinal vessels of good size. R.V.=6/60 and No. 18 Jaeger; L.V.=6/36—I.25, D. Sph.=6/12. Knee-jerks absent, even on re-inforcement. No pupillary signs. This patient furnished an excellent example of tabetic paresis (and optic atrophy) resembling a so-called "rheumatic" paresis, and easily capable of being confounded with the latter.

In "rheumatic" affections of the eye, in addition to local measures, one generally administers liberal doses of sodium salicylate, a drug that often acts admirably in relieving pain and subduing inflammation. Foucher (*L'Ophthalmologie provinciale*, August, 1904) has gone a step further, and treated three cases of rheumatic iritis by injecting beneath the conjunctiva a few drops of a 1 per cent. solution of sodium salicylate, and in another case he obtained relief to pain by injecting the same solution beneath the skin of the temple. For some little time I have employed in these rheumatic affections of the eye another salicyl compound, the name of which will certainly be familiar to all in this room, namely, aspirin. It is non-depressant, rapid in action, and seldom causes unpleasant symptoms, such as nausea and tinnitus. Administered in doses of 15 to 30 grains three or four times a day, its action upon rheumatic iritis is often surprising, while its power in relieving pain is sometimes as grateful to the patient as it is unexpected by the practitioner. It is a remedy in rheumatic diseases of the eye that I would commend to your very earnest attention. Galezowski (*Recueil d'Ophthalmologie*, 1903, p. 179) and Frank (*American Journal of Ophthalmology*, June 1904), have testified to the efficiency of aspirin in rheumatic iritis. I would add, in concluding, that the pain of severe rheumatic iritis was relieved by Frank (*loco citato*) by painting the affected parts with diluted mesotan, the methoxy-methylester of salicylic acid. The remedy should be mixed with an equal part of olive or cotton seed oil, and be painted on the affected parts, the skin having first been carefully freed from moisture.

CONCLUSION.

The limited time at my disposal has allowed me to touch only the fringe of an interesting but somewhat

extensive subject. Several new agents and methods, of which some give every promise of being of practical importance in the treatment of eye disease, have either been passed over altogether or else merely glanced at. Among these may be mentioned pressure-massage, intra-ocular disinfection by means of iodoform, and the treatment of infected wounds of the eye by intensive doses of mercury. What has been said, however, will, I hope, convince you that ophthalmology has not lagged behind the other branches of medicine and surgery as regards advances in the twin sisters of pharmacology and therapeutics. The results of that activity have made themselves felt in ophthalmic work by the introduction of new and valuable remedies, by accuracy of dosage, by precision of physiological action, and last, but not least, by convenience of application and of storage. It can be claimed, indeed, that the medicinal treatment of diseases of the eye is now, thanks to the labours of modern chemists and pharmacologists, fast approaching the position of an exact science.

A SCHEME FOR PROVIDING A RESERVE OF MEDICAL OFFICERS FOR THE R.A.M.C. (a)

By LIEUT.-COL. VALENTINE MATTHEWS,
R.A.M.C. (VOL.).

THE officers of the Royal Army Medical Corps being maintained at a strength but little above the peace requirements of the army, it is necessary to make provision for expansion during times of war. In the following notes I propose to outline a scheme for this purpose, so as to secure a reserve of officers which may be readily available in case of necessity. No doubt a certain proportion of highly distinguished medical men, as in the Boer War, would come forward and be available for special professional work, and a certain number of practitioners, whether Volunteers or otherwise, would be able to leave their practices and offer their services. Neither of these two classes would, in my opinion, be numerically large, and neither class would have any military knowledge or organisation. That part of the profession which had not settled down to practice or permanent engagements is the part from which most is to be expected. This consists of what I will call the *locum tenens* class, and of those men who have but recently qualified. Of these two, I believe the latter would be preferable. The main point is, of course, that the conditions of service shall be sufficiently attractive, and shall not unduly interfere with the future career of a newly-qualified young man who has to make his way in the world by his civil occupation. I do not think that the term of obligation should exceed one year at a time, but that, if called out during that year for actual service, the reservist medical officer should be liable for service for one year from the time he is called out. In my opinion, any longer period would impose upon the young medical men disabilities in civil life which would interfere with their future.

Practitioners would be reluctant partners or assistants with a view to partnership if they knew that their prospective partners or assistants were liable for military service; while young medical men starting on their own account would not care to risk the chance of having

to throw up what they hope to be the foundation of their livelihood. Most newly-qualified men do not settle down into practice or enter into other than temporary engagements during the first year after qualifying, and practically no damage would be done to their future by entering into an obligation to serve if necessary during this period. I think that men should be given the chance of re-engaging for a second or a third year, and possibly a good many would re-engage, but I do not think it would be a good policy to engage men for more than one year at a time. A certain amount of time would have to be spent in some military medical establishment—say, about four weeks in the first year and a fortnight in subsequent years of re-engagement.

I think that during the whole period of his obligation he should hold military rank, and wear uniform when on duty. From what I have been able to gather, the definite position given by military rank places a man on a better footing than that of a civil practitioner; indeed, I know of one instance of a civil practitioner engaged to do duty at a military hospital who applied for a commission in the R.A.M.C. Volunteers simply to get military rank. With military rank and the possession of uniform also, more men would probably be induced to re-engage for a second or third year, and also, probably, many would afterwards join the R.A.M.C. Militia or Volunteers, as then one of the obstacles to a young medical man—viz., the expense of outfit—would be partly removed. I would also suggest that men so engaging should be allowed the option, as far as possible, of service abroad or at home. I think that to most young men the idea of service abroad would be the more attractive.

By what means are young medical men to be induced to take upon themselves the obligation of service if called upon? The possession of rank and the choice of serving abroad or at home would, I think, be of attraction, but there remains the question of pecuniary recompense. Men who are dependent upon their profession will not undertake obligations which will materially interfere with their livelihood, unless it is made worth their while, and, of course, the amount offered will make all the difference both in the quantity and the quality of the applicants. What one wishes to aim at is to offer sufficient to attract men of the right kind without undue extravagance in the expenditure of public money.

The pay of a private of the R.A.M.C. is about 1s. 2d. a day, and the pay of a lieutenant of the R.A.M.C. is 14s. a day—that is to say, about twelve times as much. It seems only reasonable to assume that the value of the reservist medical officer may be calculated on a similar scale, and that his pay should be in a similar proportion to the pay of the reservist private—6d. a day. This would give the reservist medical officer 6s. per diem, or £109 10s. per annum, and it is only fair to assume that the country would be justified in spending this amount to secure his services.

I do not think, however, that it would be necessary to expend this in pay. I believe that if the reservist officer got £25 a year clear for himself, a sufficient number of men would undertake the obligation of service. He should, of course, receive the pay and allowance of a lieutenant during the period of training or of actual service, and should receive a grant in addition to provide

(a) Abstract of Paper read at the Royal Institute of Public Health, London Congress, 1905.

uniform. This amount must depend on the amount of uniform required. If full uniform is required it would cost from £50 to £70, but I should think that an undress uniform and mess dress ought to be sufficient, and a grant of about £15 would cover this. This grant would, of course, not be required in the second or any subsequent years.

The average number of newly-registered medical men added to the "Medical Register" in England, Scotland, and Ireland during the past five years is 1,268, and if all information on the subject of this Reserve of Medical Officers were made widely known through the various medical schools throughout the country, and if in addition a special circular were sent to each man on registration (for which purpose the General Medical Council and the various examining bodies might be asked to co-operate), the services of a good proportion of these should be obtained. In my opinion about one-third of these men should be available annually—say, in round numbers, 400. Of these, probably about 100 would re-engage for a second year, and say about 50 for a third year. They would all be young men fresh from their medical schools, receptive, keen, and able to carry on the whole of the work of a military hospital under the supervision of a small number of R.A.M.C. officers for the administrative and disciplinary work.

Preference should be given to those who have served in the Royal Army Medical Corps (Volunteers) in any rank, which service should also count towards seniority. This should be made widely known to students, and would have the double effect of strengthening the ranks of the Volunteers and of offering to the R.A.M.C. officers for the reserve who are already conversant, to some extent at least, with the duties for which they are asked to serve.

Each officer on the above basis would cost in his first year £40, plus his pay for the period of training, which I put at £20 for one month. If he served for a second year, and had a fortnight's training, he would cost £25 plus £10, and the same in subsequent years.

The cost of this would be in the first year—say 400 men—gratuity, £25; pay during training, £20; outfit allowance, £15 to £60.

First year	£60 × 400 =	£24,000
Second year	£35 × 100 =	£3,500
Third year	£35 × 50 =	£1,750

£29,250

So that in three years there would be 550 reserve officers at a cost of £29,250, or a fraction over £53 a head—not a large sum to have the right to call upon the immediate services of a highly trained professional man.

I believe that the scheme I have sketched out would be popular, and as the cost of each officer is less than six times that of the reservist soldier, I do not think it can be called excessive. To recapitulate, the main points are:—

1. The limit of obligation for a year at a time, with liability for a year's service if actually called out for service, from the time of being called upon.
2. The choice of serving abroad or at home—as far as the exigencies of the Service permit.
3. Military rank and status.
4. A clear £25 a year after payment of all expenses.

I have ventured to put forward these notes of a scheme with the hope that others may be induced to consider this subject, and that there may be some points in this which may be of possible assistance to the authorities who are endeavouring to provide an efficient and reliable reserve.

GANGRENOUS TRAUMATIC HERNIA. (a)

By WILLIAM TAYLOR, M.B., DUB. UNIV.
F.R.C.S.I.,

Member of the Council, Royal College of Surgeons, Ireland; Surgeon to the Meath Hospital and Co. Dublin Infirmary, and Surgeon to Cork Street Hospital, Dublin.

THE subject of my communication to-night is again, as have been most of my previous communications to this club, that of an old theme, but the case I take to illustrate it has, I think, at least one feature alike interesting and uncommon to redeem it.

The case is that of a young gentleman, æt. 27 or 28, who, on the evening of July 24th, received a kick from one of his horses on the left groin. Dr. Nolans, of Gorey, Co. Wexford, was sent for some hours later, and on arrival found, on examination, the scrotum and penis greatly swollen and ecchymosed, while the left inguinal region—the site of the injury—was also swollen and discoloured, the skin being slightly abraded over this area. The inguinal swelling crepitated on handling, giving the sensation of surgical emphysema. There was great tenderness over the swelling, and the patient complained of intense pain in it. Next day the state of affairs was much the same. There was absolute constipation, but very little vomiting. There was never any swelling in either inguinal region prior to this injury. An aperient was ordered, also enemata, but without other effect than that of increasing the vomiting and abdominal pain. Tympany of the abdomen soon appeared, and rapidly increased. Owing to the history of the injury, the swelling in the left inguinal region associated with vomiting, absolute constipation, and increasing tympany, Dr. Nolans arrived at the conclusion that the case was one of a strangulated traumatic hernia requiring operative interference as soon as possible, and accordingly sent for me. On my arrival on the evening of the third day after the receipt of the injury, I found the skin over the left inguinal region becoming gangrenous and crepitating on gentle pressure. The scrotum was perfectly black, and quite as large as a man's head. The general state of the patient was far from promising. Vomiting during the day had been severe and almost continuous, the pain had been extreme up to that day, the tongue was dry and brown, constipation was absolute, the abdomen greatly distended, the facial appearance was one of anxiety, the pulse was quick and feeble, restlessness was marked, and he had been without sleep from the time he received the accident.

The stomach was well washed out and a little chloroform administered. Having cleaned the affected area as well as we could, a free incision was made through the skin and underlying structures giving exit to a large quantity of dark brown foul-smelling fluid, mixed with gas, broken-down blood-clot, and sloughs. On douching and separating the softened sloughing tissues, a knuckle of

(a) Paper read before the Dublin Biological Club, February 21st, 1905.

gangrenous gut with a small perforation in it was discovered at the bottom of the wound. It was impossible to be certain, but, as far as we could see, the bowel was forced through the muscular structures of the abdominal wall. On account of the very septic state of all the surrounding parts, and on account of the patient's general condition, I decided simply to make a free incision into the protruding piece of gut. Having done this, the wound was irrigated and the index finger passed up the opened bowel so as to ensure that the constriction was not so tight as to occlude the lumen of the gut and prevent the exit of its contents. A tube was then placed in the bowel, and gauze packed loosely around it. An opening was made in the bottom of the scrotum, a quantity of blood-clot was removed therefrom, and a drainage tube inserted. Directions were given to wash out the stomach should vomiting recur, and to irrigate the bowel with warm water next morning if the bowels did not act in the interval. A purgative was to be administered as soon as the bowels acted. The subsequent treatment of the case devolved upon Dr. Nolans and the nurse to whose care and attention at this stage the gentleman owes his recovery. There was a free evacuation next day through the artificial opening, and everything progressed in a satisfactory manner, until, at the beginning of September, on my return from my holidays, the patient was sent up to town to me to operate for the fæcal fistula, or, rather, false anus which was bound to exist. After a few days I proceeded to operate by first closing with sutures the existing opening as accurately as I could, after which the parts were as thoroughly disinfected as was possible under the circumstances. This being done, an elliptical incision was made around the previously existing opening down to the peritoneum. At this point the intervening mass of tissues was grasped with forceps, the peritoneum opened above and below, and the mass with the afferent and efferent loops of intestine withdrawn, after separating some few adhesions within the abdomen. The abdominal cavity having been protected by gauze packing, about six inches of the intestine, including the artificial anus, were resected, and an anastomosis effected by a Hildebrand's modification of the Murphy button. The wound was afterwards closed by suturing in layers with buried catgut sutures, and the skin edges united by silkworm gut, except at the scrotal end, from which too much skin had to be removed to permit of accurate approximation. Union by first intention took place throughout the sutured area. The bowels acted naturally on the second day. The button was passed on the ninth day and the patient left for Gorey in less than a month, and has since then remained in perfect health.

The interest in this case centres round two points, the first being the nature of the hernia, which must be described as traumatic, a form of hernia which is extremely rare, there being practically no mention made of it in any of the textbooks with which I am acquainted, while any reference made to such a condition is directed particularly to the diaphragmatic variety; the second point of interest being the method of dealing with a herniated gut undoubtedly gangrenous when exposed by operation. With regard to gangrene, a further question for pathologists arises, viz., whether the mechanical arrest of the circulation is the only element of importance in

leading to its production, or whether gangrene does not more largely depend upon organismal virulence and activity. Not unfrequently a surgeon cuts down upon a hernia strangulated for two or three days and yet finds the gut in such a condition that he returns it without a moment's hesitation, while on the other hand, he has occasion to operate upon a case in which the strangulation has existed for perhaps less than twenty-four hours, and apparently no more tightly than in the former case, yet the condition of the strangulated gut is one almost, if not quite, gangrenous. Such a diverse state of affairs would surely serve to point to other factors than mere mechanical interference with the circulation, being of etiological importance in leading to the production of intestinal gangrene.

Before coming to the treatment of undoubtedly gangrenous gut when exposed in the sac of a hernia, I should like to ask for information from those members of the club whose experience is greater than my own, how they finally solve the problem as to what is to be done in those cases which are in a decidedly doubtful state, and which embrace, so far as my experience goes, by far the largest proportion of cases one meets in practice. My own practice so far as tests are concerned is to employ warm saline irrigation, after dividing the constriction and withdrawing the loop, and notice whether the circulation returns as shown by change of colour. The gut is also flipped with the finger or handle of the knife and peristalsis watched for. It is particularly noticed whether the peristalsis thus excited, travels beyond the area of constriction. The veins in the mesentery leaving the loop are also examined to see whether they are thrombosed. Of course, the site of constriction is examined the moment the gut is freed, also the most distal part of the loop. In spite of these tests, I have often found extreme difficulty in deciding whether the loop is likely to recover, and consequently what should be done with it. Hitherto, I have always returned the loop in such cases just within the internal abdominal ring, merely closing the skin round, and in no case have I had occasion to regret this step. The abdominal cavity seems the best place to ensure the recovery of a doubtful piece of intestine. It is, I think, unquestionably the case that many unnecessary resections are performed in such cases, and few will be found to deny the fact that resection will add, to place a mild estimate upon it, at least 20 per cent. to the mortality of the operation for strangulated hernia. As regards the treatment of undoubtedly gangrenous hernia, I do not think any surgeon would be so unwise as to lay down a hard and fast rule which he would make applicable to all cases. For example, to have resected the gangrenous loop and opened the abdominal cavity to perform an end-to-end anastomosis in the presence of a mass of septic sloughing tissues such as I had to deal with in the case already detailed, would, in my opinion, have meant disaster.

Again, resection, followed by anastomosis, considerably prolongs the time occupied by the operation, and many such patients are not in a fit state to withstand prolonged operations. To leave a large gangrenous loop in the sac of a hernia—merely making an incision into it—would undoubtedly be unwise, as the increased septic absorption therefrom would surely add the last straw to the patient's already overtaxed recupera-

tive powers. In such a case, if the patient's condition is one of gravity, resection of the greater portion of the affected loop, as it lies in the sac of the hernia without touching the constricting band, would probably be the line of treatment from which the best results might be anticipated. Resection and immediate restoration of the continuity of the intestinal canal should, in my opinion, only be undertaken where, in the first place, the patients' condition is otherwise good, and secondly in cases in which perforation has not yet taken place, and, consequently, in which the gangrenous process has not spread to the surrounding tissues, no matter whether the affected loop be large or small. The treatment of the affected area in cases of partial enterocele, of which I have met with three examples in the sac of a hernia—two of which occurred in successive weeks—is always one of considerable anxiety, when the ensnared portion involves more than one-third of the circumference of the bowel, but if less than this amount is involved the difficulty is easily overcome by enfolding the affected area by a purse-string suture, and applying a couple of Lembert sutures over this again, at right angles to the long axis of the intestine.

One other question arises in connection with gangrenous hernia, viz., should a radical cure ever be attempted in cases in which resection and immediate anastomosis has been performed. My own reply would be certainly not. Sepsis is pretty certain to occur in the wound, and the attempted radical cure will be a failure.

To sum up, I should say that in all doubtful cases of partial enterocele involving one-third or less of the circumference of the bowel, the affected area should be enfolded and the loop returned into the abdomen. In all doubtful cases of partial enterocele involving more than one-third of the circumference of the bowel, the treatment should be the same as that for ordinary doubtful cases of strangulated hernia—that is, return the loop just within the internal ring.

In undoubtedly gangrenous partial enteroceles involving one-third or less of the circumference of the bowel, enfolding the gangrenous area by a purse-string suture reinforced by a Lembert suture applied over it at right angles to the long axis of the gut, would appeal to me as the proper course to adopt, while, should the gangrenous process involve more than one-third of the circumference of the bowel, resection of a couple of inches of the bowel followed by immediate anastomosis (lateral or end-to-end, as the case may be), if the patient's condition is otherwise suitable, should be adopted. If the patient's condition is not considered suitable for immediate anastomosis the loop should be withdrawn, the gangrenous portion cut off and the ends drained by Paul's tubes.

In either large or small gangrenous herniæ, if the loop has not perforated, if the gangrenous process has not spread to the surrounding tissues, and if the patient's condition is suitable, resection, of not only the affected portion but of a considerable portion both above and below the area of constriction, followed by immediate anastomosis, should be performed.

In small, gangrenous herniæ, which have perforated or in which the gangrenous process has spread to the surrounding tissues, or in which the patient's condition is bad, a free incision into the

affected loop without interfering with the constriction will give the best results.

Large gangrenous herniæ, which have perforated, or in which the gangrenous process has spread to the surrounding tissues, and in which the patient's condition will, in all probability, be extremely grave, are best treated by cutting away the greater portion of the gangrenous loop, and leaving the wound open for free drainage, the constriction being left untouched.

The Out-Patient Departments.

SALFORD ROYAL HOSPITAL (PENDLETON BRANCH).

Summer Diarrhœa in Infants.

By STANLEY HODGSON, M.D., B.S.Lond.,
Hon. Physician.

ALTHOUGH in the vast majority of cases the children who are the subjects of this scourge have little or no stamina with which to resist its attacks, yet occasionally one happens on a well-developed and previously healthy child in whom active measures are sometimes fruitful. One is then struck by the hopelessness of the usual methods employed when the patient is not treated in hospital. Much of the procedure is admittedly impossible under the conditions which surround the sufferers in their homes, but it is open to question whether the most is made of the resources available even to the poorest. The death of these infants is due, not so much to toxic absorption, as to collapse from the relatively enormous loss of fluids. The free watery diarrhœa and the copious vomiting quickly drain the organism of all its spare fluid and the rapid, feeble pulse is a physiological result of this desiccating process. It is hopeless attempting to supply the deficit by the mouth, and subcutaneous or intracellular infusion is only possible in skilled hands. But there remains the rectum. There is always someone in the very poorest quarters who possesses an enema-syringe, and no child should be allowed to end in collapse without some attempt at supplying the necessary liquid in a rational manner. As an example of what can be done in this direction, a child of eleven months was brought to my out-patients' department in the sixth day of diarrhœa. The child was obviously what the mother described as a "fine baby," but it was equally obviously very near death. The mother had tried every variety of food, including albumen water. The vomiting and diarrhœa had in nowise abated. The child was almost pulseless, the muscles were flabby, the abdomen shrunken, and the eyes "hollow." The child had not sufficient energy left to resist palpation of the abdominal viscera. Salicylate of bismuth with tinc. camph. co. was ordered, more with a view to gaining the mother's confidence than in any hope of its efficacy. The belief in medicine as such is very deeply rooted in the poorer classes. It was directed that in the event of the medicine being vomited it was not to be repeated. The condition of the patient was explained to the mother, and she was told that the only hope for the child lay in its retaining water given rectally. All feeding was absolutely forbidden and the giving of water by the mouth was also barred. The mother was told to wash out the child's rectum with warm water and then give half a pint of isotonic saline solution (90 gr. to Oj.). She was told to do her utmost to prevent this saline being returned, and to repeat the injection in four hours' time. The mother carried out the instructions to the letter, with the gratifying result that in four days the child was practically well. An ordinary rubber enema-syringe, borrowed from a neighbour, was used for the injections.

This case was very striking. No drug treatment, brandy or strychnine, could possibly have helped the heart, which was failing for want of fluid resistance. But the first half-pint of water that was absorbed effected a visible improvement.

Special Articles.

EARLY HISTORY OF THE MEDICAL PROFESSION AND OF HOSPITALS.—II.

MEDICAL SCIENCE IN THE SECOND CENTURY.

IMMEDIATELY preceding the era of Galen, medical science had succumbed to the deplorable influences of contentious and zealous sects. Galen's advent arrested the complete downfall of medicine as a scientific method of cure, and maintained through his authoritative exposition the outlines at least of treating maladies for centuries upon the basis of a reasoning philosophy. Born in the city of Pergamos, in Asia Minor, towards the close of the first portion of the second century, he began his useful existence amid the cultured surroundings of a municipality long celebrated for its temple dedicated to Æsculapius, the colossal dimensions of a carefully selected library, and its school of medicine. In the scientific treatment of his medical essays he unequivocally asserts that he is totally disconnected with and unattached to any of the numerous sects which divided the profession of his day.

The Galenic system of medicine thus established by the practical skill of its founder upon the most accessible materials which intelligent zeal could use, was so servilely followed throughout the Middle Ages in a deteriorated adaptation, and conjoined with the assumed potency of external but divided influences, that a short outline of the same is necessary. According to this methodical treatment of medicine, there were in man three principles or actuating impulses—spirit, humours, and solids. Inasmuch as he accepted the dynamical forces of the soul, or pneuma, with Hippocrates, he also admitted the four primordial qualities of heat, cold, dryness, and humidity, which in their individual or united action, sufficiently influenced the transformation of the human system. He owns three original powers—natural force located in the liver, vital force in the brain, and sensual force in the heart, which were vitalised in their respective habitations by a concealed pneuma or soul. These natural essences, which directly supervise the action of production, nutrition, and growth, in their turn are controlled by four—the attractive, differential, preservative, and exclusive powers, and collectively act under the domination of a circulating spirit which moves through the arteries and have their central organism in the liver, where the veins originate, blood is prepared, and nutriment distributed to the entire body. From the character of Galen's distribution of the sanguinary fluids throughout the veins, it is a rational conclusion to assume his practical acquaintanceship with the circulation of the blood, to whose knowledge the utility of venal valves was alone essential to complete the universality of his anatomical learning. In addition to pagan philosophy, Galen was well versed in the doctrines of Moses and in the religion of Christ; but the partial obscurity of his superstitious deism induced him to sneer at their teachings. To what extent the treatises of Galen may be of practical service in modern times, they must be awarded the high commendation of securing subsequent medicinal art from total wreckage during the turbulency of the Middle Ages, and assisted at its revival into an embellished science through the mediæval Universities. From the time of Galen to the close of the sixteenth century, the works of the Pergamic sage fully satisfied the demands of the practitioners of medicine, who depended on his surgical and anatomical writings, without questioning their authority.

CHEMISTRY AND MEDIÆVAL PHARMACY.

Of all appliances closely identified with medicinal art, the one rendering the most signal returns for efforts strenuously devoted to penetrating and exploring the secrets of nature, and boldly appropriating the principles thus obtained to scientific curatives, alchemy is certainly entitled to unstinted laudation. Out of that burning frenzy of mediæval alchemists and astrologers to fabricate the "philosopher's stone," arose, towards

the fifteenth century, the exact science of chemistry, and from absurd notions of astrology originated a more perfect astronomy. Alchemy, vigorously pursued with unremitting energy by illustrious scholiasts, and after the accumulated learning of years pronounced by a famous scientist to be a mendacious fraud, in its medical association, may justly claim the high commendation of establishing that system of extracting essential principles from metals or minerals, whose energetic forces abundantly assisted the cure of maladies. Whether derived directly from Arabic sources, or traceable to Egyptian hierarchy, as a portion of those hidden sciences exclusively possessed by the ancient priesthood, doubtless its medicinal adaptation should be awarded to the Saracens.

It would seem that the Christian clergy of an early age understood sufficiently the operations of chemistry to be able to control the results of the judicial hot iron and water adopted as tests of enormous crimes. The general principles of this science were certainly known in Diocletian's time, by the order of whom Egyptian books on this subject were given to the flames.

Perhaps the highest practical discovery of these pharmacists was that of the essential force of aquafortis, by whose solvent virtues brass or copper was readily separated from gold or silver. This system of purging valuable metals from useless dross was utterly unknown to the ancients, according to the utterances of an illustrious jurisconsult, who declared when brass became amalgamated with gold it was impossible to separate them. Chemists in the Middle Ages were so profoundly skilled in these operations, disuniting the elements indicated, that oftentimes silver in alloy, when disintegrated, under the soluble virtue of aquafortis, ascended in columnar shape, emitting variegated colours, and when thoroughly washed, and nothing of this substance was visible in a vase of water, the pure gold was found resting at the bottom. An additional purifying element, largely used in those ages, was the cupella, fabricated by a chemical process from bones, which enabled gold and silver smiths to purge their wares of every particle of impurity or alloy. It appears to have been operated by covering the finer metals with laminated sheets of lead, beaten very thin, and placing them in a crucible exposed to intense heat. When liquefaction had melted these substances, the above preparation was mingled with the molten mass, which caused a precipitate of pure gold, and denominated "Aurum de Cupella" by Italian alchemists.

Processes of distillation were used at remote periods of the Middle Ages in order to procure medicaments in such suitable and attractive forms as to admit of readier acceptance by the sick. Among these may be designated the aqua vitæ, or eau-de-vie, as its name implies, life-potion; oil of cinnamon and herbal extracts, such as chicory, &c., with precipitates in the nature of medicinal salts—all were applied to the cure of diseases. The preparation of these oils and waters is certainly traceable to the year 1080. In the year 1160, Mesne had already made distillations of absinthe and rose-water. To Villanova, should be accorded the praiseworthy adaptation and first precise description of eau-de-vie, or brandy, prior to the end of the thirteenth century. In his treatise on the preservation of youth, he explicitly states that the virtues of this potion were already fully known to many by actual experience. Then, describing its amazing properties, Villanova exclaims: "Who would believe that from wine can be extracted a fluid which requires different processes, having neither the colour, nature, or effect of wine? This eau-de-vie, or life-potion, abundantly justifies its name, since it prolongs human life." Rival physicians of the fourteenth century exhausted the entire range of panegyric in order to enlarge the use of eau-de-vie as a medicament. So great, indeed, was its celebrity, that before the conclusion of the era mentioned it came to be regarded as a universal remedy, and applied indifferently, either externally or internally. This liquor was prescribed for a malady of Charles the Bad, King of Navarre, and, by a singular casualty, caused his death in the year 1387. In order

to rejuvenate this exhausted royal libertine, physicians ordered him to be wrapped in linen bandages saturated with brandy sewed closely to his body. A servant charged with this duty, lacking scissors to cut the thread, sought to sever it with a lighted taper; instantly the inflammable texture was fired, and quickly terminated in inexpressible agony the life of this prince, stained with infamous debauches.

In the Italian monasteries, and doubtless elsewhere, until after the Middle Ages, the conventual pharmacies were well supplied with this active stimulant, used almost exclusively in grievous maladies, and prepared by the monastic distillery. As usual in the administration of remedies to the poor, this medicine was freely given to the impotent and impoverished, consequently large quantities were ever ready for emergencies. The persons entrusted with the custody of curatives or medicaments in the cloister pharmacy were distinctively named from an early period as apothecaries—a service of so great importance as to receive from time to time, specific regulations by the principal church synods.

HOSPITALS IN THE MIDDLE AGES.

From the monastic infirmary and hospitium was developed a system for the regular aggregation and treatment of sickness and diseases under rules and ordinances whose careful execution contributed to practical mediæval philanthropy. In that signification, this department of conventual organisation is of high antiquity, and as early, indeed, as the age of Charlemagne, such separate apartments were used exclusively for sick persons. They afforded a practicable means of exhibiting in practice the fundamental principles of conventual charity in providing food for the impoverished, lodging for the houseless, and medical treatment for diseased strangers. By whatever series of eventualities this monastic institution passed from the strictest interpretation, and survived as a hospital, or edifice entirely set apart for reception and cure of maladies, may perhaps be gleaned from notions touching its more ancient purposes, which, under ecclesiastical manipulation, necessarily were remodelled towards the end of the twelfth century. In the year 1059, a hospital exclusively for sick girls had long been extant at Durham.

At a much earlier period, however, there were organisations of this character among the Spanish Arabs, together with poor-houses solely occupied by the indigent and pauper people, entirely supported by public funds, in the year 976. When Benjamin Tudelensis was at Jerusalem in 1173, the Christian people maintained an institution of this character exclusively for their own sick. Eight years later, Roger de Moulin promulgated a series of regulations for these eleemosynary organisations in this city, which may have been suggested by earlier rules. By these ordinances, each hospital should have four physicians skilled in diagnostics, pharmacy, &c., and a like number of surgeons. To these were added nine *sergens*, or assistants as menials, to provide ready service for the feeble and wounded.

Knights of the Hospital Order, whom these regulations principally controlled, were detailed to a day and night watch over the sick, and, indeed, for this attendance the hospitaliers of either sex were liable. For ready use syrups or electuaries were applied as potential curatives. These compounds, it has been stated, were unknown to the Western monasteries at this period, and their existence in this venerable ordinance attests the rapid appropriation of Arabic drugs by crusading adventurers.

In the form of gratuitous attendance upon the sick and diseased, the Eastern Arabs in the eighth century possessed a regularly organised system of public infirmaries in the great metropolis of Bagdad. In the time of Benjamin, the Hebrew traveller, A.D. 1173, a most efficient and practicable scheme had long existed in this city, for the reception of the disabled and infirm poor into hospitals thoroughly equipped with sixty salaried physicians and completely furnished with pharmaceutical supplies. But transcendent and above

this form of philanthropic benefaction, called into existence by enlightened Moslem economy, was a most thorough organisation of a public establishment at Bagdad for the custody and care of the insane, brought thither from all parts of the Persian empire. Here the inmates were subjected to scientific medical treatment until sanity was restored, when the patient returned to his domicile, where he received professional attendance for several months to prevent a relapse into the malady of which he was cured.

Hospitals for the sick, orphanages for foundlings, and great institutions for the proper care of paupers, developed with immense strides, under the thoughtful and judicious zeal of their founders, and during the twelfth century expanded into gigantic proportions. In the ensuing age, the mediæval mind was fired with a faith in the efficacy of unstinted charity, members of society from the Holy Pontiff himself to the humblest cloistered recluse by the wayside, rivalled each other in gratuities of food and clothing, founding of hospitals and endowment of beneficent public institutions. St. Louis' highest claim to pious glory arose from his restless and unstinted charities to the indigent and sick. The intercourse of this king with the diseased in hospitals, where he entered to administer personal consolation, utterly oblivious or indifferent to the dangers of such nursing, may be taken as an important attestation of the extension of this virtue toward benevolent enterprises during the Middle Ages. The internal arrangements and thoroughly practical nature of the ordinances to which the mediæval hospitals owed their existence, excite surprise and demand unreserved admiration.

PARIS, August 26th, 1905.

INDICATIONS OF DIGITALIS.

HITHERTO it was taught by authorised clinicians that digitalis had a beneficent action on mitral lesions of the heart, alone; that in all other cases of cardiac disease, especially in aortic lesions, it was useless or dangerous. But recent experiments have shown that digitalis was useful in every case of weakness of the myocardia (symptomatic asystolia) whether due to organic lesion of the heart or from chronic disease of the respiratory organs, such as emphysema, chronic bronchial catarrh, well known to provoke cardiac asthenia.

Asthenia of the heart can be also the consequence of interstitial nephritis of arterio-sclerotic origin at the period when the hypertrophied myocardia degenerates, accompanied by dilatation of the heart. In such cases the administration of digitalis can raise the tone of the head.

The same cardiac insufficiency is observed in the course of infectious diseases and wherever there exists general depression. It can follow the abuse of coffee, tea, alcohol, and tobacco.

According to Eichhorst, digitalis is the surest remedy we possess against persistent cardiac asthenia.

As to the mode of administration of digitalis, Prof. Eichhorst employs exclusively the powdered leaves, but he associates with it diuretine (salicylate of soda and theobromine):—

Powdered leaves of digitalis, 2 grs.;

Diuretine, 16 grs.;

Sugar, 6 grs.

For one wafer. Three daily, and continued ten days. By this means the patient takes 2 grains of digitalis three times a day, which constitutes the dose for an adult; with smaller doses the effect desired is not obtained, while larger doses might provoke anorexia, nausea, vomiting.

In certain cases of arterio-sclerosis of the arteries, tabagism, alcoholism, or gout, one or two wafers daily should be given, and continued, without interruption for weeks. In cases of dyspnoea and cyanosis it is frequently necessary to associate with digitalis, stimulants—brandy and water, champagne, injections of

camphorated oil (10-100). The effects of the digitalis are shown by an increase in the diuresis. The quantity of urine in twenty-four hours rises to two quarts, and sometimes much more, and where œdema or dropsy is present it is absorbed.

While the patient is submitted to the treatment, he should be carefully watched by the medical attendant. Immediately the pulse falls below 60, the treatment should be suspended, otherwise the patient would be exposed to certain accidents: lypothymia, cerebral troubles, Cheyne-Stokes' respiration, &c.

TREATMENT OF ERYSIPELAS.

The best treatment, according to Prof. Robin, consists in spraying the parts with a warm solution of bichloride of mercury at 1-1,000, with 20 grains of tartaric acid added to each litre to prevent the formation of albuminate of mercury. The steam apparatus should be employed when possible, and held about a foot and a half from the face of the patient. The eyes should be bandaged and the mouth kept closed. The pulverisation should last from twenty to thirty minutes, and be renewed six or eight times during the first day, and also the following day, if improvement have not taken place. Generally on the third day a manifest improvement is observed, when the number of séances may be reduced, and so on until the end of the malady.

The treatment by warm antiseptic solution is simple in its application, free from danger and remarkably efficacious. The general treatment consists in milk diet, and the administration of tonics:—

Ext. of cinchona, 1 drachm ;
Brandy, 1 oz. ;
Gum julep, 4 oz.

A tablespoonful every hour. In no case of erysipelas should rinsing of the mouth and nasal irrigation be forgotten:—

Naphthol, 4 grs. ;
Borate of soda, $\frac{1}{2}$ oz. ;
Peppermint water, 4 ozs. ;
Boiled water, ad one quart.

Lotion for urticaria:—

Thymic acid, xv. ;
Phenic acid, xxx. ;
Proof spirit, 6 ozs.

Rub the parts with absorbent wool moistened with the mixture.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, August 26th, 1905.

THE DIAGNOSTIC IMPORTANCE OF SOME SKIN AND TENDON REFLEXES.

During the last thirty years some of these reflexes have reached a high stage of importance, the value of which has been clearly set forth in an article in the *Fortsch. d' Medizin*, by Hr. M. Rothmann, Berlin. Amongst the reflexes studied those of the Achilles tendon are not the least interesting and important. The reflex of special importance is that in commencing tabes, whilst the patella reflex is still retained the loss of it in one or both tendons of Achilles, will render the diagnosis certain. Frequently, when the Achilles tendon reflex is absent the plantar reflex may be produced by tapping the gastrocnemius, distinct evidence in favour of the spinal reflex theory (Erb) as opposed to the muscular theory of Westphal. The question as to whether tendon reflexes can be produced when the brain is entirely separated from the spinal cord must be decided in the affirmative.

The skin reflexes are much more complicated than those of tendons. Whilst we are far from being acquainted with the reflex tracts in the human subject, the author has succeeded in mapping them out in the dog. Babinski's reflex is very important. Strong dorsal flexion of the toes, especially of the great toe, when the skin of the external margin of the foot is irritated. It renders certain the diagnosis of organic spastic as opposed to fundamental spastic paralysis (hysteria). In weakening of the over-powerful influence of the

cortex of the brain (spastic diplegia, epileptic coma, pseudo-bulbar paralysis, removal of the brain in dogs), or touching the hard palate of dogs, their lips, tongues or other parts of the mouth. Rhythmical movements of the lips, tongue, and muscles of mastication take place, which are to be looked upon as movements of tasting, sucking, chewing, and swallowing. It is plain that here old phylogenetic relationships come again into play, now that the cerebrum is partially or entirely removed. The author believes that further inquiry into the field will lead to great results, not only to the neurologist but to the practitioner.

FATAL POISONING WITH BALSAM OF PERU.

Such cases are exceedingly rare, and the one reported by Dr. Deutsch in the *Zeitsch f. Med. Beamt.* is interesting not only for its rarity, but as an illustration of the ravages of quackery.

Four children of the peasant class, of ages from 5 to 13, became affected with scabies. A quack basket-maker was consulted. After seeing one of the children he declared the illness to be a bad itch and ordered a blood-purifying tea, and after that an ointment prepared by himself to be rubbed in. The last procedure caused sores on the skin and great pain. On this being reported to the basket-maker he ordered balsam of Peru and sulphur in a wash; after the bath the balsam was to be painted on the sore made by the ointment. This treatment was kept up for several days. One of the children, and the strongest, a boy, æt. 11, then had swellings in the eyes, hands, and feet, and could pass but little urine. When this circumstance was communicated to the quack he ordered senna tea with liquorice and juniper and said that the condition was not bad (nicht für schlimm). But as the condition of the boy got worse the two younger brothers also showed signs of swelling, and the writer of the paper was called in. The three children were admitted into hospital, and the eldest was already unconscious and died in uræmic convulsions the same night, in spite of all that could be done; the two others recovered. In all three children the urine was albuminous more or less; it contained cylinders, both hyaline and granular, and both red and white blood corpuscles.

The post-mortem examination showed œdema of the skin and distinct nephritis, in addition to traces of scabies.

The quack was summoned and tried. Nothing could be ascertained as to the composition of the ointment. He received a sentence of six weeks' imprisonment for culpable negligence—the negligence lying in the fact that even after the swellings had made their appearance he persisted in the use of the Peruvian balsam. The case should certainly serve as a warning, as it appears that really very little Peruvian balsam was used. Unfortunately the report does not give the number of sores, nor the extent of surface covered by them.

The *Deutsch Med. Zeitung* relates a case of

ANURIA WITH RECOVERY

by Dr. Moschkowitz.

The patient was a man, æt. 48, who was admitted into hospital on November 25th, 1903. For about five years he had had pain in the right side of the abdomen. That had been supposed to point to appendicitis. During the last two years he had several attacks of lumbago. On November 15th he had a violent attack of pain in the region of the right kidney; that required repeated subcutaneous injection of morphia. Early on the morning of the 22nd, urine ceased to be excreted. The patient vomited several times, he complained of nothing more, however, but the idea tormented him that in spite of all his efforts he could not empty his bladder, but he felt no desire to micturate. Palpation was not practicable owing to obesity. A diagnosis of calculous anuria was formed, and an operation was performed within 48 hours of the setting in of the suppression. Nephrotomy was performed, and a stone found in the pelvis of each kidney, and also an obstruction in the ureter about six inches from the skin incision. The perirenal

fat on the left was oedematous. Notwithstanding the desperate condition of the patient he rallied quickly, and from the next day the urine came away so freely that in spite of frequent change of dressing he lay in a lake of urine. On December 29th the condition had become sufficiently favourable for further treatment. A bougie showed obstruction in both ureters, about six inches deep on the right and seven on the left. The blocking was so complete that fluid injected into the ureter immediately returned. On cystoscopic examination it was imagined that a calculus could be seen embedded in the mouth of the left ureter. Examination by X-rays was unsatisfactory. On January 14th, further operation was proceeded with, and in lieu of the appearance of a stone in the mouth of the left ureter epicystotomy was performed. No stone was found, but the opening of the bladder was made use of to pass bougies into both ureters temporarily. Then the right ureter was exposed to the right of the extraperitoneal incision, a concretion the size of a large date stone was found above the liver arcuata and removed. The wound in the ureter was closed by catgut sutures and the abdominal wound sutured in layers. Drainage with strips of iodoform gauze. Union took place by first intention and on the first day 130 c.cm. of urine were passed naturally. The patient recovered so rapidly that a further operation could be performed on the fourteenth day. This was exactly like the former one, except that the calculus was smaller and it lay an inch deeper, and consequently took more working out. Union by first intention again took place. The wounds into the two kidneys also healed rapidly, so that the patient could be discharged by February 10th.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, August 26th, 1905.

DANGERS OF VENOUS ADRENALIN INJECTIONS.

FISCHER told the members of the Wiesbaden Congress that he had been operating on guinea-pigs and other animals with injections of the suprarenal body which produced hard patches and aneurysms in the aorta. Closer investigation prove the smooth middle coat to be necrosed in patches, subsequently becoming calcified, and associated with bands of broken degenerate elastic tissue.

The order of pathological change seems to be, first mesarteritis destroying the arcus aortæ and aortæ thoracicæ and finally closing with the endarteritis. In the heart myofibrosis, myocarditis interstitialis with sometimes calcification of the cardiac muscles. Sometimes the animals are attacked with varying forms of apoplexy. When this pathological change in the arteries is not so far advanced the toxic substance carried into the system by the venous injections produces a sort of cachexia of a fatal character. The question that occurs to us, is the arteriosclerosis in the animal the same as that met with in the human subject? In the former it seems to be a poison that produces necrosis and may thus differ histologically. There is some peculiarity in the difference of tissue as this arterial change was not observed if the drug was injected into the subcutaneous tissue, neither did it occur in the vessels of dogs when injected intra-venously, although it did in guinea-pigs. It would seem that different animals have different reactions.

Külbs said he had experimented on animals also with the suprarenal body and found that after single doses of an adrenalin injection sclerotic changes could be found in the aorta, but never in the peripheral vessels.

Albrecht remembered similar results he obtained some time ago when experimenting with this substance on animals, and passed it over as the aortitis luetica of man, as casually looking at it gave that impression.

CHEMICAL PRODUCTS IN CHRONIC NEPHRITIS.

Rumpf gave the results of 2,000 analyses of the blood with the object of deciding the controversy

whether sodium chloride is burned up in nephritis. It may be that a large number of the nephritic cases may have a large amount in the diseased kidney, and that a large accumulation of sodium chloride produces oedema and becomes a check to diuresis, thus eliminating less chloride of sodium than the healthy kidney. There are cases where the opposite prevail, thus pressing us to the conclusion that the increase or reduction of chlorine has no specific effect on nephritis or its eliminating power. He agrees with other observers that when the kidneys begin to shrink the solids are increased and the fluids diminished, and that at different stages some constituent of the urine may be suppressed. He is not satisfied with our present estimation of chlorine calculated as sodium chloride, as the acids and bases do not accurately give a true estimate of the final salts. In disease a large amount of ammonia is present in the different organs which it is necessary to estimate. In hepatic cirrhosis he found, as other investigators, an increase of 13 per cent. NH_3 , in chronic nephritis it was 9 to 13 per cent., giving about 1 gramme of ammonia in the 24 hours. Now, by feeding and giving sulphates with acid phosphates of ammonia the salts are transformed and broken up, leaving the acid for elimination as before, while the blood is deprived of sodium and enriched by chlorine. Rumpf believes that a similar reaction takes place between ammonia and chlorine.

INFLUENCE OF TEMPERATURE ON SUGAR ELIMINATION.

Lüthje told the Congress that external temperature had a wonderful effect on the elimination of sugar in the diabetic. He wounded the pancreas in dogs and kept them in rooms of different temperatures. When the temperature was high less sugar was eliminated, when low it was increased. This, he thinks, will be of therapeutical value, as the elimination of albumen is unaffected. This fact, he thinks, confirms Rubner's theory on the thermal splitting of the albuminoid molecule into nitrogen free and nitrogen fixed. How far this high or low temperature may be carried in the treatment of the diabetic is yet a matter of speculation, but Lüthje thinks worthy of experiment.

Klemperer said that he had often observed this fact in patients he had sent to Carlsbad, as they never recovered so well in the winter as in the summer. These experiments also proved the utility of keeping the patients warm in bed and giving alcohol in several cases.

Embsen supported Lüthje in affirming that he had experimented in the same manner with dogs and had obtained similar results. He had gone further in his operations by wounding two large dogs which he had hungered and kept under similar temperatures. The daily output of sugar was similar in both cases when exposed to different temperatures.

LUXATIO TESTES.

Jurinka relates a very rare case of dislocation of the testes. The patient fell from a waggon and displaced the testes into the hip joint. Laparotomy was performed immediately after, and the flattened testes found between the ends of the bones in the hip joint. Castration was performed, the wound drained, and the patient made a good recovery. Such a luxatio femoris præcotyloidæ has nowhere been recorded. The hip joint seems to have been dislocated and the testes thrown between the heads of the bones, where they became entangled.

Hungary.

[FROM OUR OWN CORRESPONDENT.]

BUDAPEST, August 26th, 1905.

At the last meeting of the Budapest Royal Society of Physicians and Surgeons, Dr. Kombi read a paper on

RENAL LITHIASIS IN INFANCY.

During the last two years the reader has made 160 necropsies, and has observed at least 70 cases of renal lithiasis in one form or another in nurslings. Amongst these there was not one case of biliary calculus. Renal lithiasis may occur in the form of uratic dust which may be observed as yellowish striæ in pyramids.

Gravelly concretions and calculi are also found, and in some cases may be observed during life in the urine, especially in extreme cases of inanition and malnutrition. A condition known as inanition fever has been described by American practitioners, and is found in newly-born children who do not receive a sufficient supply of milk or fluid nourishment. This fever is to be attributed to the deposition of uratic material in the kidney, though no evidence may be found in the urine. Bokay points out that normally, during the first few days of life, the urine is extremely rich in uric acid, and that by the end of the second week its more usual characters are assumed. The reader has more particularly observed 23 cases of which 14 were boys and 9 were girls. The majority of the cases occurred under the age of six months, and all were due to bad feeding, inanition, and "misère physiologique." Of the total number 20 were reared by hand. In addition to the uratic dust observed in the pyramids, gravel and hard calculi, angular or rounded in form, were found in the pelvis of the kidney and the calices. They consisted of urate of sodium, and it is possible that troubles arising at a later period of existence may have their ultimate origin in such early formed calculi. In some instances pyelitis or hydronephrosis was observed. The symptoms were obscure as the regular signs of renal colic were absent. Crying, general uneasiness, screaming during micturition or retention of urine may all be symptoms. The prognosis should be reserved. Fatal results may follow; in case of survival, renal colic, cystitis or vesical calculi may occur.

Prophylactic treatment should be observed in insisting on ample and proper nourishment at the earliest period of life, although overloading of the stomach should be avoided. Weaning should not take place too soon, and during febrile attacks plenty of water should be given to facilitate the excretory action of the kidneys. If the stomach be extremely intolerant of food, &c., lavage of that organ or injections of artificial serum may be employed. If the lithiasis be confirmed the child when older may undergo a "cure" at the corresponding baths.

KOPLIK'S SPOTS NOT CONSTANTLY PRESENT IN MEASLES.

Rolli has looked for the spots on the buccal mucous membrane, first described by Köplik as preceding by some days the general eruption of measles, and has found them in 24 cases. In one case they preceded the eruption by six hours, in 11 cases by one day, in 5 by two days, in 3 by 1½ days, and in 2 by four days. The spots were generally situated on the mucous membrane of the cheeks opposite the molar teeth, but occasionally on the lips—beginning as slightly raised, bluish-white, circular, sharply-defined points, in size less than a pin's head, and surrounded by a narrow red areola. In a few days they generally increase slightly and become more prominent, and the areola enlarges and becomes more irregular in outline. Their number varied between 6 and 20, and the time during which they persisted from two to six days. They were not marked just before, or at the time of the general eruption. They were not present in 14 cases (17.1 per cent.). Since they are never seen in other conditions accompanied by fever, they are of the greatest importance for the early diagnosis of measles. Rolli claims that the buccal eruption in measles was first mentioned by Gerhardt, and that their importance was recognised by Filatow in 1895, a year before their independent discovery by Köplik.

The authorities at Cambodia in French Indo-China have decided to establish at Phom-Penh a general hospital and a lying-in hospital for natives. The work of construction will be commenced immediately.

A CONTEMPORARY medical journal suggests that an appeal should be made to the Home Secretary to order an immediate inspection of the mortuaries attached to London hospitals and medical schools, urging that at some of them the existing arrangements are fraught with danger to medical students and teachers.

Continental Health Resorts.

[FROM OUR OWN CORRESPONDENT.]

BADEN-BADEN AND THE BLACK FOREST.

BADEN-BADEN continues its popularity! This is natural considering the abundance of attractions for all classes of visitors and all nationalities. It is the most French-like of all German resorts in its appearance, and in the characteristics of its truly cosmopolitan *habitudes*. In its management care is shown to provide for the tastes of many guests. Its races have long been famous. Its tennis-lawns among the best known for position and condition. Now its Golf-links have (thanks to private liberality and able control) a cosy club-house; and, a point golfers should never overlook in choosing a temporary home, these grounds are the most easily accessible from the town of all Continental links.

The Reading-rooms at Baden are especially convenient and well supplied; the theatrical entertainments and concerts (in and out of doors) remarkably artistic. The hotels are unexcelled anywhere; and the society, both native and foreign, is of the best. A quiet, aristocratic, well-assured tone marks the whole place. As an enduring basis for its high position and its future prosperity Baden-Baden rests upon the intrinsic merits of its Mineral Springs, the acknowledged repute of its physicians, the skilful management and scientific perfection of its State Bath establishments and its medical institutions. Among the latter may be mentioned the private Sanatoriums, Groddeck, Frey and Gilbert, and Ebers.

The thermal waters (used for bathing, douches, irrigations, and drinking), vary in temperature from 110° to 157° Fahrenheit; their most important components are the chlorides of lithium and sodium, and arsenic; and their efficacy is unquestionable for rheumatic gout and stomachic complaints.

The location (650 feet above sea-level) at the entrance of the Black Forest is most picturesque and healthful, the public grounds and avenues are very agreeable, and the vicinity in every direction is charming.

The annual visitors exceed 70,000; and for their accommodation are an abundance of capital hotels, pensions, and apartments. Among the principal hotels are the Angleterre, Bellevue, Europe, France, Holland, Messmer, Minerva, Park, Regina, Russia, Stephanie, Victoria, Zahringerhof, &c.

FREUDENSTADT.—At 2,000 feet altitude in the Württemberg section of the Black Forest, Freudenstadt is regaining its old-time popularity. Like many German resorts, during the acrimonious days of the Boer War many of its old clients went to other summer homes; but with this era of better international feelings, British visitors are again seeking in annually increasing numbers the attractive and salubrious regions of the Black Forest. To those desiring a restful sojourn, or to recuperate over-worn energies, for the convalescent and contemplative, for the lovers of Nature, and of the forest landscapes, Freudenstadt can truly be highly recommended. Especially in these September and early October days, when pleasure trippers of July and August have gone home. For the disciples of Izaak Walton the trout streams here are captivating! The pine forests in this district, vast dark fir woods, intersected by blithely flowing streams and deep green glades, are widely noted for their beauty and healthfulness; affording with their numerous foot-paths every facility for the fashionable Continental *terrain-cure*. There are many good hotels; notably *The Schwarzwald Hotel*, from whose proprietor (Mr. Luz), or from Mr. Hortranft, Stadt-Schul-Haus, Freudenstadt, all particulars can be freely obtained.

WILD-BAD.—This other Württemberg Spa must not be overlooked when writing about the Black Forest. Located on the northern limit of the Forest, 1,500 feet above ocean-level, amidst romantic and rugged scenery,

and with a climate adapted for a comfortable residence, from early April to late October, Wild-Bad possesses Mineral Springs of great value in treatment for chronic complaints of the bones, joints, scrofula, metallic poisonings, lameness, cramps, neuralgia, nervousness, gout, &c. It has fine fishing and shooting, tennis and croquet grounds, theatre, library, conversation rooms; and good hotels, as Klumpp's, Russie, Concordia, Bellevue, Belvedere, and Blumenthal Pension.

Operating Theatres.

ROYAL FREE HOSPITAL.

OPERATION FOR RUPTURE OF THE URINARY BLADDER.

—Mr. T. P. LEGG operated on a man, æt. 28, who had been kicked in the abdomen about eighteen hours previously. When admitted, the patient was under the influence of alcohol, and the only history obtainable was that he had been kicked. There was no bruise or other sign of injury to the abdominal parietes. The abdomen was a little distended, moved freely with respiration, and on percussion an impaired note was found in the right iliac fossa. The liver dulness was absent. The patient complained of pain coming on in paroxysms in the epigastric and umbilical regions; his pulse was small and 96 per minute. These were all his symptoms, except a great restlessness. It was evident from the symptoms that some grave abdominal lesion had been sustained, and immediate operation was decided upon. A catheter was passed into the bladder, and a quantity of blood-stained urine was drawn off in a slow stream; this at once suggested that the bladder had been ruptured. An incision in the middle line of the abdomen with the umbilicus corresponding to its centre was made, and the peritoneum having been divided, a large quantity (between three and four pints) of urine and blood escaped. On passing the hand into the peritoneal cavity downwards towards the bladder region the laceration in the wall of this viscus was easily felt on the posterior aspect. The incision was now prolonged downwards and just above the symphysis pubis, the intestines were allowed to escape partially from the wound, and the peritoneal cavity was flushed out with a large quantity of sterilised saline solution, the escaped intestines being wrapped up in warm towels. When the abdominal cavity had thus been completely washed free of the urine, the patient was put in the Trendelenburg position; the bladder was then easily drawn up to the parietal incision; the laceration was found to be entirely intra-peritoneal, horizontal in direction, and two inches in length, the edges being regular and infiltrated with blood. It was closed by two layers of continuous catgut sutures, the first and internal layer was passed through the muscular coat and the deeper part of the mucous membrane in such a way that the inner surface of the mucous membrane was not penetrated; the outer row of stitches was passed through the serous and muscular coats of the bladder. A drainage tube was placed in Douglas's pouch and brought out through the lower angle of the abdominal incision. A No. 10 catheter was tied into the bladder. Mr. Legg remarked that rupture of the bladder was not a very common accident, but for this very reason, and because it usually occurred in patients in a condition similar to this one, as a result of such an injury as a kick or a violent blow, it must always be borne in mind by the medical attendant, and a catheter should always therefore be passed at the earliest possible opportunity

In another class of cases, the rupture of the bladder, he pointed out, was a complication of fracture of the pelvis, and in all these cases a catheter should be passed. The diagnosis, he considered, was not always easy, even when a catheter had been passed; blood-stained urine being withdrawn suggested injury to the bladder or damage to the kidney. If the rupture of the bladder was intra-peritoneal, a good deal of help in the diagnosis might be obtained, he thought, by putting in through a catheter, a known quantity of sterilised salt solution or boracic lotion, and then measuring the quantity which can be withdrawn, whether it was greater than that put in, if it were blood-stained, and the force with which it returned; if the amount was considerably increased this means that urine is also coming back with the solution; if the bladder were intact the stream would be full and forcible. When a rupture was present the stream is slow, and varies with respiratory movements. Absence of evidence of injury to the abdominal parietes he deemed of no value in helping one to diagnose the presence or otherwise of intra-abdominal injuries; this particular case, he pointed out, was a good example of most serious damage being sustained with no external signs of injury. The character of the urine had, he pointed out, an important bearing on the prognosis; if the urine is healthy, peritonitis is late in coming on; when the urine is foul and septic the reverse holds good, and the prognosis is correspondingly bad. When the operation is done the peritoneal cavity must, he insisted, be thoroughly flushed out, and all urine got rid of at once, and to do this effectually it was necessary to allow the intestines to escape at least in part through the long parietal incision. In closing the rent in the bladder, he pointed out, stitches should not penetrate into the lumen of the bladder, and should be preferably of catgut, which is readily absorbable. A continuous suture was more quickly inserted than interrupted ones and was equally efficacious. With reference to tying in a catheter, Mr. Legg thought that this was perhaps safer, as it prevented urine accumulating in the bladder, and therefore there was less risk of the latter becoming over-distended and leakage occurring through the wound into the peritoneal cavity; it would be safe to remove the catheter about the third or fourth day, and subsequently, to pass it every four hours. The alternative method was to pass the catheter at regular intervals of four to six hours, thus preventing any over-distension of the bladder. It is advisable he considered to put a drainage tube into Douglas's pouch for the first day or two in order to prevent any accumulation in that locality. For the successful treatment of ruptured bladder early operation he considered was essential. Excluding septic peritonitis, the main cause of death, he said, was shock and collapse, which in these cases was generally very great.

Unfortunately the patient collapsed and died a few hours after the operation was completed.

ST. PETER'S HOSPITAL FOR STONE.

SUPRAPUBIC LITHOTOMY.—Mr. SWINFORD EDWARDS operated on a man, æt. 63, who had been admitted with obscure symptoms of stone in the bladder. The patient had been sounded several times with different results; on the last occasion the surgeon thought he detected a calculus. Cystoscopy was performed at St. Peter's, but a good view of the interior of the bladder was not obtained owing to some prostatic

hæmorrhage. As but little could be learnt in this way, the bladder was emptied by means of a catheter, and with two fingers in the rectum and simultaneous deep pressure being made suprapubically, Mr. Edwards was able to detect what he believed to be a large calculus. He elected to do a suprapubic lithotomy forthwith without first trying litholapaxy. Therefore, the bladder was distended with about sixteen ounces of hot boracic solution and the usual suprapubic incision made in the mesial line. On exposing the anterior bladder wall the injection of more fluid did not seem to make much difference in the distension of that part of the bladder which felt quite hard. An incision was made through the bladder wall, and this immediately cut on to a rough calculus which was tightly grasped by the surrounding bladder wall. An incision of two and a half inches in length was required to extract an unusually large spiculated oxalate of lime calculus of the size of a golf-ball. When the bladder wall was incised, there was no escape of the fluid in the viscus, nor did this find its way out until the stone had been extracted, a proceeding in which there was some difficulty, owing to the sharp spiculae on the stone and the tightness with which it was grasped by the bladder wall. On the extraction of the stone there was a copious rush of the fluid with which the bladder had been distended, and the finger passed through an opening in the bladder proper. Mr. Edwards estimated the opening between the sac and the bladder to be about the size of a new florin. The bladder was found to be quite clear of all calculous formation. The opening between the sac and the bladder was now dilated by means of the fingers, and after the insertion of a *coude* catheter per urethram the incision into the bladder wall (or wall of the sac) was closed with cutgut sutures. The rectus abdominis was also sutured and lastly, the integuments, only a small gauze drain being left in. Mr. Edwards remarked that this was not an instance of an ordinary sacculus communicating with the bladder, for these sacculi are usually found to have no muscular coat, being generally formed of herniated mucous membrane, a layer of fibrous tissue and peritoneum when in that portion of the bladder which is covered by this membrane. In this case the wall of the sac was as thick as the wall of the bladder proper, and Mr. Edwards was inclined to regard it rather as a specimen of hour-glass contraction of the bladder, the upper chamber of the hour-glass contraction being entirely occupied by the stone. The stone itself was a beautiful specimen of a mulberry calculus, and was quite the largest and most regularly spiculated Mr. Edwards had ever seen.

The patient made an uninterrupted recovery.

Mortality from Plague.

THE vital statistics relating to the Punjab for 1904 show a lamentable mortality from plague, which alone accounts for a death rate of nineteen per thousand, and the total death-rate for the provinces reached forty-six per thousand. It is not generally recognised, writes the India Correspondent of the *Lancet*, that plague carries off the flower of the population and not the very young or the aged. The infantile mortality has been affected hardly at all. The Sanitary Commissioner estimates that the population has been reduced by nearly 1½ per cent. since the census of 1901.

THE Sanitary Inspectors' Autumn Conference, held at Carpenters' Hall, London, has been largely attended under the presidency of Sir J. Crichton-Browne.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 30, 1905.

MEDICAL ASPECTS OF THE AGAPEMONE.

THE medical profession is clearly concerned with the various bodily and mental actions of mankind, both in their healthy and their diseased manifestations. Of all the mental disturbances it is called upon to investigate there can be few more important than that of sexual aberration. The necessity of an exact scientific study of that complex region of psychology is now widely recognised, but nevertheless it may be pretty safely asserted that while the labourers therein are few and far between, the field to be explored is still of the widest. When, however, lack of sexual morality is coupled with mental delusions, the diagnosis is to that extent rendered easier, for in that case the erotic manifestations are in all probability concurrent symptoms of insanity. Keeping these points in view, it will be interesting to discuss briefly some of the issues raised by the doings of a so-called religious sect that has recently been brought prominently before the public. Some years ago a Church of England clergyman, seceding from a previously formed sect, announced that he was the Christ and was gifted with all the attributes of the Almighty. Although originally a poor man, he has managed to bring a large amount of wealth to his peculiar community from wealthy persons who have been induced to join the sect. A large property has been bought at Spaxton, Somersetshire, where a number of persons live in strict seclusion in a luxurious retreat known as the Agapemone. The leader of this body, the Rev. J. Smyth-Piggott, a married man, has recently registered the illegitimate child of which he is admittedly the father. The mother is one of a number of young women who reside in the Spaxton abode. From published interviews it appears that some of the inmates, at any rate, are firmly persuaded that both Piggott and the infant are divine personages. From the medical point of view this brief history reads like a remarkably clear account of delusional insanity, accompanied by sexual manifestations, especially if we take into consideration the reports which

persistently attach sexual immorality to all stages of the origin and progress of Piggott's mission. At the same time, it is only fair to assume that some of his disciples are sincere in their emotional surrender, and are free from any sexual taint. The question now arises, how is this matter to be dealt with in the best interests of the community? If this man be mentally irresponsible there should be some means of staying the terrible harm he is causing to the weak-minded persons who believe in his insane delusions, and whose property he is said to have acquired. If, on the other hand, he simply calls himself the Messiah in order to secure the bodies and the goods of his dupes, then he should be amenable to the criminal law. There appears to be no way out of that dilemma. Either Piggott is mad or not mad. In the one case he should be brought under the control of the Commissioners in Lunacy, in the other he should be tried for conspiring to defraud. That a man should be permitted under any conceivable set of circumstances, whether he be knave or madman, to go on working havoc among the weaker members of the community is a supposition that cannot be for a moment tolerated. Some means must be found by intervention of Government, if necessary, to put a stop to the scandal. At first sight it would seem an easy matter to put the lunacy law into action against a person who publicly and repeatedly asserts himself to be Christ returned to earth. A similar assertion is to be heard a hundred times daily within the walls of our lunatic asylums. Should a formal official investigation fail to demonstrate sufficient grounds for declaring Piggott to be insane, the police by that time will in all likelihood have gathered sufficient facts to warrant their interference. Of this we feel assured, that to permit a body of persons to seclude themselves in a kind of private fortress, while their published utterances are of a kind to warrant a *prima facie* suspicion of insanity, is to incur a public danger of a grave nature. The subject, however unsavoury, should be dealt with promptly and thoroughly on medico-legal grounds that we have considered it our duty as a scientific journal to indicate.

HOSPITAL ISOLATION IN SCARLET FEVER.

LAST summer a series of articles questioning the value of hospital isolation in scarlet fever appeared in THE MEDICAL PRESS AND CIRCULAR, and we were so far moved by the facts and arguments brought forward by our contributors as to express a strong opinion that a public inquiry into the whole subject was called for. Naturally our contributors approached the question from different standpoints, and each expressed views that were not received *in toto* by the others; but they were unanimous in the opinion that the extensive provision of isolation hospitals for the treatment of scarlet fever had not resulted in any definite fall in the incidence of the disease, and, seeing that the system had been in operation for a consider-

able number of years, they considered that the apparent failure of these hospitals to fulfil their primary function, namely, that of disease prevention, called for careful inquiry into the factors at work. Beyond all reasonable doubt such a case was made out. It is interesting to observe that though no official inquiry has been instituted, the demand for it not only has not abated, but, on the contrary, has grown in force, and that many medical officers of health who till recently were of the "orthodox" faith, have come to regard the utility of these hospitals as questionable. In fact, the isolation hospital as an article in the sanitary creed has had so many doubtful adherents, that it is quite permissible for such doubts to be openly expressed without their author being shouted down as a fool or a knave. That, at least, is an advance, and pending an inquiry which must come sooner or later, it is well that the points at issue should not be lost sight of. Most of these found expression in the discussion on the value of hospital isolation that took place in the State Medicine section of the annual meeting of the British Medical Association at the end of last month. This discussion was opened by Dr. George Wilson, Medical Officer of Health for Mid-Warwick, a hygienist of wide experience in rural sanitation. From an exhaustive examination of the returns in his own area he stated he had elucidated the striking fact that those districts which were without hospital accommodation actually sustained a lower incidence-rate from scarlet fever than those districts with hospitals. Moreover, as the case-mortality showed no appreciable difference in either, it was difficult to contend that the great expense entailed by the up-keep of the hospitals had proved of any particular advantage to the districts that had provided themselves with hospital accommodation. On further analysis of the figures, he had found that more than half the cases occurring in non-hospital districts were single ones, and in hospital districts when the patients had to be retained at home owing to the hospitals being full, the same phenomenon was noted. Dr. Wilson contended that as a preventive measure against scarlet fever, the hospitals were practically valueless as they neither reduced the incidence nor the fatality of the disease, and a far more economical plan would be for the authorities of rural districts to have power to provide nursing for scarlet fever patients, together with compensation to breadwinners who were debarred from following their employment owing to the presence of infectious disease in their homes. Following on the same side came Dr. Whiteside Hime, Dr. J. E. O'Connor, and Dr. F. H. Waddy, the last-named presenting conclusions derived from perhaps the most complete inquiry that has yet been made in any single town. A number of medical officers of sanitary authorities, including Dr. Boobbyer, President of the section, combated the arguments advanced, but in the end a motion in favour of asking the Local Government Board to institute an inquiry into the value of isolation in scarlet

fever and diphtheria, was carried by the section. This resolution, following as it does on a similar one carried in the Preventive Medicine Section of the Congress of the Royal Institute of Public Health last year, and others of a like nature passed at various other gatherings, during the intervening twelve months, is significant of the change of mind that is taking place on the subject. In his annual report for 1904, Dr. J. C. Eames, Medical Officer of Health in the Kearsley Urban District, writes: "Hospital treatment (for scarlet fever) has proved quite incapable of stamping out the disease, and it is an open question as to whether it even diminished the number." Dr. Martin, Medical Officer to the Gorton Urban District Council, in his annual reports for 1903 and 1904, writes in a similar strain, and, indeed, as long ago as 1895 he expressed the opinion that scarlet fever could, with certain precautions, be treated at home with but little fear of spreading. The opinions of medical officers of large towns like Portsmouth and Leicester are of a like trend, and are well known to our readers. Nor have their views failed to reach members of sanitary committees and town councillors all over the country, many of whom are actively interesting themselves in a question that involves the expenditure of so large an amount of the ratepayers' money. It would be premature at present to say that there is no value in hospital isolation as a preventive measure, and the convenience that these institutions afford to medical officers of health and to poor patients is obvious; but it is plain that hospital isolation has failed to make any deep impress on the incidence of scarlet fever, and that it is attended by many undesirable features. "Return" cases are frequent and cause much annoyance to medical officers and the public, and the number of cases sent into hospital under erroneous diagnoses has attracted invidious comment. Both of these drawbacks appear to be inevitable accompaniments of the hospital system, while medical knowledge of scarlet fever is as little exact as it is at present. By such an inquiry as is proposed, the credit of the profession in regard to these reproaches would be re-established, and nothing but good would result if it were shown how by some modification of the present plan, isolation could either be made effective, or limited to those cases that are attended with special danger to the public, such, for instance, as occur in laundries and dairies. We hope that the matter will not be allowed to rest where it is.

NEW ORLEANS EPIDEMIC OF YELLOW FEVER.

THE departure of the eminent experts, Professor Boyce and Major Ronald Ross, for the suffering city of New Orleans forms, we trust, an abiding landmark in the history of preventive medicine. At present the perusal of the columns of the daily newspapers of that city resembles a good deal that of an historical romance. The "yellow jack" has appeared, without official invitation,

in its midst; and although not quite so murderous in its progress as in some former visitations, it has aroused the municipality and citizens to an activity which may be characterised as heroic, and the result is that New Orleans is having such a washing, brushing, and scraping—and all-round cleansing—as it has never received since the day of its original baptism. The physical environments of the city are decidedly unfavourable. It lies 18 feet below the surface level of the "Father of Waters," from which it has to be continuously fenced off by its famous "levee." The result is that drainage can be carried out only by a pumping arrangement, and the erection of covered drains is now in progress throughout the city. Then the chaos of swamps which surround the city forms a colossal difficulty, as they have hitherto represented an ideal paradise planned and watered for mosquito residence and revellings. And the absolution by flat streets of the city form another engineering obstruction. But on this occasion the collective citizenship of New Orleans seems to have sprung to its feet for combined and heroic effort against the invasion of the common foe. In addition to the employment of a vast army of street cleaners of the regulation type, thousands of volunteers are working hard day after day—visiting houses seriatim, discussing with the residents the most appropriate methods for purification of standing water, teaching the value of oiled cisterns, and impressing upon the careless and the fatalistic the incalculable importance of the use of the mosquito net. All public uncleanness is pointed out and dealt with, and all sanitary offences are brought under the notice of the Board of Health. It is not a matter now of every resident fulfilling to the letter every sanitary commandment with regard to his own dwelling, and the corresponding half-breadth of street before the same; every active citizen of New Orleans has become a member of the sanitary host which is fighting the deadly invader in every part of his city and its surroundings. "Successful" and "dignified" merchants and financiers are acting as volunteer superintendent scavengers, and some have even given manual assistance in every detail of the work. From pulpits of all denominations flows Sunday after Sunday a torrent of the most inspiring eloquence, asking all true citizens to give time and money to the common cause. Public meetings are held daily for the purpose of evoking enthusiasm in the sanitary campaign, and at every one the eloquence of the speakers is rewarded by the enlistment of numbers of volunteers who offer their assistance in the most unpleasant details of the sanitary engineering. Ditches are already conveying water to the canal from quarters where it had previously been stagnant and furnishing luxurious conditions for mosquito life. The whole face of New Orleans is said to have been transformed within a few weeks. And the highest testimony to the discipline and public spirit of that city is furnished by the fact that in no single instance have the volunteers

come into collision with the professional members of the Public Health organisation. Under such circumstances, while we condole with the citizens of the great western community in their calamity, we cordially congratulate them on the public spirit and patriotic self-denial which have been brought into so conspicuous prominence by its occurrence.

Notes on Current Topics.

The Danger of the Sleeping Cars.

WE have the very highest authority for the validity of the statement that the increase of knowledge carries with it the increase of sorrow; we are assured by moralists—and the assurance is corroborated by the universal experience of ages and nations and individuals—that every vicious gratification of sensual proclivities is sure to be followed by penitential consequences, and our dispassionate and mechanical twentieth century seems to be continuously discovering that every increase of physical comfort, and development of (apparently innocent) luxury is bound to convey its shadowy surface of tainting influence with it in its progress. The bathos of such discouraging revelation would almost seem to have been sounded by Dr. A. W. Wiley in a recent address to Columbia University on "The Physician of the Future." "It is difficult to imagine any contrivance which human ingenuity could construct better calculated to secure the best conditions for disease and the best methods for the propagation thereof than the sleeping car." The lecturer indicated the principal physical reasons for the faith which existed within him on that interesting subject. He pointed out that the vehicle in question is constructed in such a way that ventilation is practically impossible; how it is partitioned into small compartments—carefully curtained so as to prevent any circulation of fresh air, if any fresh air happen to be within reach; provided with enough heating surface to the cubic yard to complete the installation of a Turkish bath; manned by porters to whom a high temperature is an evidence of heavenly bliss; and, accordingly, represents an ideal hot-bed for the growth and culture of germs, as well as entailing obvious physical drawbacks which require no microscope to see and no æsthesiometric tests to confirm. Some little time ago a railway company announced with (what professed to be) honest pride that the blankets of its sleeping cars were always washed at least twice a year! And these compartments may often carry, without any precautionary inspection, persons in all stages of phthisis, and even other contagious diseases. "There is no health officer to inspect incoming passengers, no provision of the law requiring complete fumigation, and no systematic appliance of any kind to prevent or eradicate disease." Of course, there is nothing of all this; and we cordially thank Dr. Wiley in the name and interest of a long-suffering and

much-abused public for pointing out so forcibly the existence of such a glaring want. We will further express the hope that Dr. Wiley's pronouncements may ultimately have the same effect on the twentieth-century sleeping-car that John Howard's had on the eighteenth-century gaol. Having regard to lapse of time and growth of knowledge—and of sensory nerves, one summation is now to be as devoutly wished as was the other then.

Metropolitan Asylums Board Report.

THE annual report of the Metropolitan Asylums Board grows in bulk and in interest every year, the duties of the Board having now expanded to such an extent as to include the administration of seventeen hospitals, five asylums for imbeciles, fifteen schools for children suffering from ring-worm, ophthalmia, and similar complaints, eight ambulance centres, and a training ship. No less than 21,721 patients passed through the fever and small-pox hospitals during 1904, 21,183 of these patients suffering from fever or diphtheria, and 538 from small-pox. The mortality rate, except in the case of enteric fever, was slightly higher all round than in 1903, but the difference was fractional only, and it is significant of the mild type of scarlet fever that has prevailed of late years that the case-mortality only stood at 3.37 per cent. in 1904, and 3.10 per cent. in 1903. The diphtheria mortality-rate maintains the very satisfactory level that it has stood at for the last few years. In 1904 it was 10.08 per cent., only some 0.4 per cent. higher than in the preceding year a benefit largely attributable to the free use of antitoxin. It must be remembered, however, that the term diphtheria is used in a much wider sense now than it was ten years ago when antitoxin was introduced, and that a large proportion of the cases are only "bacteriological" diphtheria. The value of antitoxin is proved—if any further proof were needed—by the interesting figures given showing the results of treatment in different days of disease, the mortality rising consistently with time that elapses between the patient being taken ill and antitoxin being administered. There was a distinct increase in the number of days of detention of patients in hospital as compared with the previous year in each disease except small-pox, and it is noticeable that scarlet fever patients are kept longer than any others. The period of treatment of this disease has stretched from the traditional six weeks to no less than nine, a fact that has an important bearing on the cost of isolating the disease.

Breast v. Hand Feeding.

EVERY mother and every nurse has her own theory of how a child should be fed. This one prefers milk; that one a particular brand of patent food; the other favours biscuits, bread, potatoes, or even worse things. The medical practitioner should have only one theory—namely, the breast. This natural organ of nutrition has

yet to be replaced in the rearing of children, and it would be well for the fact to be brought home to every mother, or prospective mother. In his annual report on the health of Stockport, Dr. Meredith Young, the Medical Officer of Health, gives some remarkable figures that have come to hand in his department. During the past year, he has employed his two female inspectors in visiting every house in which a birth has occurred, and reporting on the progress of the child and its method of feeding. In all, 1,477 houses were visited, in 57 of which the child had died. Of the rest they found that of the 977 children fed by the breast, 957 (98 per cent.) were healthy, and only 20 (2 per cent.) were delicate. Of those partly breast and partly hand-fed—80 in all—57 (71·25 per cent.) were healthy, and 23 (28·75 per cent.) were delicate. Of the hand-fed children, a class including 363, only 115 (31·68 per cent.) were healthy, and no less than 248 (68·32 per cent.) were delicate. Of course, a certain number included in the last class may have been withdrawn from the breast because the mother was in bad health, or because the child did not thrive, but there is no denying the striking significance of the statistics Dr. Young presents.

Music as a Mental Stimulant and Anodyne.

THE *Morning Post* has recently been concerning itself, and, we think, very judiciously, with the value of music in education. In its issue of July 29th, 1905, there is an account of a very interesting and suggestive interview with Mr. Cecil Sharp on the subject. It had previously contained an article on "The Teaching of Patriotism," in which the great value of music in cultivating the national spirit was forcibly emphasised. This is a fact which should require no argumentative details to support it. That was a keen observer of human nature who told his contemporaries—political and all others who might feel concerned—that if he were allowed to make the ballads of a nation he would allow anyone who liked make its laws. Let even his strongest political opponents and his bitterest personal enemies manufacture all the materials of the national code, he, the ballad-maker, would still remain king of the country. And the pre-scientific empiricism of the fighting nationalities sent their men into battle accompanied by the sound of horn, bagpipe, fife, and drum, &c. There is a sound physiological basis for such statements and practices, and explanation of their admittedly effective results. The effects on the circulation, in the case of all highly strung nervous systems, of the various kinds of music are so continuously under our notice that they have, like other familiar objects, almost ceased to be regarded as matter for critical discussion. Their existence—once striking—comes to be ignored, like the presence of the loud-ticking bedroom clock. The recommendation of music in medicine has been recently treated in medical journals of the strictly advanced type with a display of amused contempt. Yet its influence on the nervous system is unde-

niable; and has occasionally, in various ages of the world, received the most impressive testimony. Saul employed David to soothe his melancholy with the notes of his harp. Clinias, the famous disciple of Pythagoras, displayed one of the most characteristic traits of his philosophy by always flying to his harp whenever his temper became seriously disturbed. Pliny tells us that "Asclepiades, a noble physician, as oft as he had phrenetic patients, or such as were unhinged, or evil affected in their minds, did make use of nothing so much for the cure of them, and restauration of their health, as symphony and great harmony and consent of voices." Also, that Ismenias, the Theban, "used to cure divers of the Boeotians of the sciatica, or hip-gout, by the use of musick." And we learn from Philostratus that when Apollonius asked Canus the Rhodian musician, what he could do with his instrument, he told him that he "could make a melancholy man merry, and him that was merry much merrier than he was before; a lover more enamoured, and a religious man more devout and more attentive to the worship of the gods." Such theory and practice retained at least a smouldering vitality down to the iconoclastic revolutions of modern science. It displayed a convulsive activity of scintillation in the treatment of the epidemic tarantulism of Southern Italy, after which it almost—if not quite—disappeared from view.

Paddington and the L.C.C.

AN interesting situation has arisen between the Borough Council of Paddington and the London County Council. It appears that the Paddington authority for the execution of the Public Health Acts have after all these years failed to provide themselves with so essential a piece of sanitary equipment as a disinfecter. This fact is in itself sufficiently astonishing, but it is even more so that, having given the contract for disinfection to a private firm, they should have allowed the process to be carried out in an unsuitable place and in an unsuitable manner. In a report made by Dr. Hamer to the County Council in 1902, it is stated that not only were the premises used for disinfection unsatisfactory, but that the vans conveying the infected articles were unloaded in a public street, and the articles themselves were carried across the foot-path to the firm's premises. The matter having been reported to the County Council, a letter was written to the Paddington Council, drawing attention to the facts, and asking for observations thereon. As the result some changes were made by the Paddington Council, and steps were taken to obtain the co-operation of the Kensington Council in the erection of a disinfecting station. But plan after plan failed, and after two years, no satisfactory arrangement having been made, the County Council have, after much correspondence, informed the Paddington Council that they have no alternative but to make a formal complaint to the Local Government

Board, under Section 101 of the Public Health (London) Act, asking the Board to make an order to have the work executed. In default of which the Board will have to enforce their order by a writ of mandamus or appoint the County Council to perform the duty. It is disgraceful to think that the Council of a rich West End borough of London can only be forced efficiently to carry out its obligations by compulsion, and that the authority responsible for the public health should be so little heedful of its own duty.

The Registrar-General's Weekly Return.

THE weekly return of the Registrar-General for London and seventy-five other towns shows various points of interest. The highest death-rates per 1,000 living from all causes are those of Sunderland 23·2, Grimsby 23·7, Hull 23·8, Manchester 24·2, Henley 24·2, Wigan 25·9, Tynemouth 27·2, St. Helens 27·3. Deaths from diarrhoea reach 7·6 in Norwich, 7·7 in Sheffield, 9·7 in East Ham, 10·3 in Hull, 11·3 in West Ham, and 12·2 in Grimsby. It is interesting to note that not a single case of small-pox was registered in any of the seventy-six towns, a fact that may be commended to the consideration of the anti-vaccinationists. In London the average was 17·0 last week as against 14·3, 15·6, and 17·3 in the three preceding weeks. During the four weeks ended on Saturday, August 19th, the death-rate averaged 16·1 per 1,000, being 3·8 per 1,000 below the rural rate in the corresponding periods of the ten years 1895-1904. The deaths from diarrhoea, which had been 187, 314, and 372, in the preceding three weeks, rose to 395, and were 3·1 above the corrected average. Of these 395 deaths, 379 were those of children under five years of age: 33 deaths were in Stepney, 26 each in Hackney, Poplar, and Southwark; 25 in Lambeth, 24 in Islington, and 22 in Fulham, all of them, be it noted, poor and densely populated districts; 55 deaths were due to different forms of violence, and in all of them inquests were held.

Hygiene in Schools.

It is satisfactory to learn from the speech made by Lord Londonderry in opening the Congress of the Royal Institute of Public Health in London at the end of last month, that the Board of Education were duly impressed by the weight of the deputation of the medical profession that recently waited on the President to urge the teaching of hygiene and temperance in schools. That the seed sown by the deputation did not fall on stony ground is shown by the fact that the Board is about to issue a memorandum embodying suggestions as to how such teaching should be carried out, and we shall be interested to see the plan they propose. It is, as Lord Londonderry remarked, a comparatively easy matter to say that an hour a week is to be devoted to the teaching of hygiene, but it is quite another to insure that the hour will be well spent. It seems that the Board have been bombarded with suggestions

from all sorts of well-meaning people, but that most of these have aimed at turning out pupils versed in all the subtleties of physiology and pathology. It is obvious that for a course to be of any value to elementary school children, it must deal almost entirely with the practical results of scientific knowledge and their applications to the circumstances of life, and it is comforting to know from his own lips that the President of the Board is fully alive to the dangers of abstruseness in such teaching. Surely, however, on the principle that who drives fat oxen must himself be fat, it is necessary to start with the instruction of the teachers who are to communicate knowledge to the children. Till all the masters and mistresses themselves are well grounded in hygienic principles, it is ludicrous to expect them to impart instruction to their charges. A good beginning might be made by using as a practical example the working of the schools themselves, a good many of which in many parts of the country can hardly be described as models of healthy construction and management.

All is Not Gold That Glitters.

THERE is little doubt that many consultants, both physicians and surgeons, not to mention specialists, live habitually beyond their means. They get appointed to the staff of a hospital and promptly embark on a house in Harley-street, and perhaps a carriage and pair. They have a butler and footman and entertain lavishly. They make a point of attending every social function to which they can obtain an invitation, and the public applauds their efforts. Their days and nights are thus taken up in frivolity. They contribute nothing to medical science or literature, and their hospital work deteriorates in quality. Their professional brethren cease to value their opinion and their consulting work falls off. The climax may be long postponed, but after a time there are rumours of financial embarrassment, the position becomes untenable and the scene ends abruptly. It is found that no provision has been made for the wife and children, and the hat goes round often without any tangible result. Those who have lived quietly and within their means are but little inclined to contribute their guineas and the inevitable has to be faced. It is a pity that such things should be, but the public attaches much importance to show, and too often medical flesh is weak enough to play up to their foibles in that particular direction.

An Undertaker's Gratitude.

AMONG the callings more or less intimately allied with the practice of medicine, that of the undertaker must regretfully be included. In spite of a good deal of sarcasm to the contrary, it is after all true that the doctor's business in life is to rob the undertaker of his employment, just as the medical officer of health seeks to cut down the demand for the medical practitioner's services. As the world is at present constituted there does

not appear to be any great likelihood of either doctors or undertakers being permanently out of employment, and in spite of a falling death-rate the undertaker's business can hardly be classed among Mr. Chamberlain's "decaying industries." One undertaker, at any rate, is flourishing, but with a degree of *sang froid* that presumably springs from enthusiasm for his vocation, he has lately forwarded £5 to one of the Bishop of London's funds as a thank-offering, "because trade is good just now." We presume that most people would not regard the circumstances leading to this gift as a subject for any particular thankfulness, but every man is entitled to his own opinions, and the contributors to the undertaker's prosperity would probably prefer that the surplus should go to the Bishop's funds than to the furnishing of a wake, or whatever is the usual form of jubilation among undertakers. We reflect sadly that we did not hear of any bounteous donations to charitable funds from the public vaccinators during the late epidemic of small-pox in London.

False Charge Against a Chemist.

FROM a case tried in a West London police court last week, it is evident that chemists have unfounded charges brought against them just as happens now and then with medical men. The charge was one of maliciously administering chloroform to a young woman of no occupation, with intent to commit some indictable offence, "or so as to endanger her life, or to inflict on her grievous bodily harm." The prosecutrix stated that she felt faint and went into the shop of accused, and asked for sal volatile. She took the draught given her, and after that remembered nothing until she found herself lying on a sofa upstairs. On leaving the shop later with her sister she was seized with a hysterical fit. Defendant stated he had given her a draught of sal volatile with chloroform water. It is possible that the faint smell of the minute quantity of chloroform in this mixture may have suggested the idea of drugging to a young hysterical woman. We are glad to say the case was dismissed by the magistrate with the remark that there was nothing in the evidence to suggest that any impropriety was offered to the lady. At the same time it would be wise for any chemist under similar circumstances not to take patients into private rooms.

The Medical Examination of Volunteers.

THE present Government appear to be bent on a deliberate policy of exasperation, so far as the volunteers are concerned. The obnoxious order of Mr. Arnold Forster for the medical examination of volunteers as to fitness for foreign service has been partly enforced by Mr. Arnold Forster taking a mean advantage of the disciplinary powers of commanding officers over volunteers in camp. Our vigilant contemporary, *Truth*, calls attention to an incident in this connection which we would fain hope for the credit of the War Office is capable of satisfactory explanation. The statement is that

the Welsh Border Volunteer Brigade was persuaded with some difficulty to go through the obnoxious examination. Then came a special medical delegate from the War Office to examine the recruits. These men, it is said, were paraded "in the most public part of the camp, stripped in the most indecent way, and medically examined before the eyes of a large number of curious spectators of both sexes, and amid the jeers of a portion of the crowd." Mr. Arnold Forster seems bent on the extermination of the Volunteer force. He seems curiously blind to the political unwisdom of rousing the opposition of so large and important a body as that branch of the auxiliary forces.

Dr. Doyen's Proposed London Cancer Home.

THE public newspapers during the last few weeks have contained almost daily references to the intention of Dr. Doyen to found a home for the treatment of cancer in London. In a matter of this kind we feel it to be the duty of a medical journal to express clearly the attitude likely to be taken up by the profession with regard to this proposed step. Of special homes and special treatment for cancer there are already far too many in the United Kingdom. No cure for that terrible malady is yet known to medical science, except in some recent surface forms which are curable by certain modern methods. But cancer in its ordinary sense is incurable, although prompt and thorough removal at an early stage by the surgeon's knife may prolong life for many years or even indefinitely. Why should Dr. Doyen add to the discredited treatments with which our countrymen are already overrun? A medical tribunal of the highest and most irrefragable nature has inquired into his "system" and found it wanting. Why should he try to introduce his treatment on a commercial basis into England? The only alternative, so far as we can see, to commercial enterprise is sheer and unadulterated obstinacy. It is impossible, however, for scientific men to doubt the accuracy of the sweeping condemnation of the Doyen methods pronounced deliberately by the Paris Academy of Medicine. There is no professional jealousy in the question—witness the untiring efforts of our scientists on this side of the Channel to disclose the baffling secrets of this disease. If Dr. Doyen comes here at all let him come as a philanthropist and give his treatment gratis to all alike, free of suspicion of commercial taint.

Oysters and Typhoid Fever.

THE oyster has recently been receiving from the sanitarian and the bacteriologist an amount of scientific attention which is probably unprecedented, even in the peculiar experience of the luscious bivalve. Dr. Klein's researches, which were undertaken on behalf of the Fishmongers' Company, went to show that while the influence of the oyster pollution on the general prevalence of typhoid fever had been probably a good deal

exaggerated by popular opinion, the effect was nevertheless one of material dimensions, and sufficiently important to call for further study of the means of prevention. A French Commission, under the directing control of Professor Girard, has recently been examining the question, and his report—markedly cautious and conservative as it is—is drawn up on corresponding lines. He has no doubt that typhoid fever may be transmitted by polluted oysters, while he still believes that some of the cases cited in testimony of the fact are based on questionable evidence. He points out, emphatically, that the bacterial diseases of the oyster are not transmitted to man. The United States investigations confirm these conclusions. Dr. G. W. Fuller, of the Franklin Institute, declares that: "Those who do not recognise any relation between the pollution of shell fish and the causation of disease have either not looked into the matter or have biased views for commercial reasons." A remarkable feature of the United States census reports is that the death-rate attributed to typhoid fever is nearly double the average normal among men collectively grouped as "sailors, pilots, fishermen, and oystermen." It has, of course, been suggested that oyster-beds might be purified of germ contamination by treatment with copper sulphate—a bactericide whose valuable qualities have recently been rewarded by special notoriety. From the results of the investigations carried out by our own War Office, it would, however, appear that the anti-microbial powers of CuSO_4 have been over-magnified; a solution 1 in 10,000 being the weakest which can destroy the typhoid germ. That proportion would prove in itself dangerous in continued use. And what gourmand could ever be induced to take his naturally most palatable tit-bit freshly dripping from a solution of emetic "blue-stone"?

PERSONAL.

WE understand that Dr. Jameson, the Cape Premier, who is at Carlsbad, has now completely recovered from his recent indisposition.

ON the first Thursday in October, the Secretary of State for War will lay the foundation stone of the new cavalry barracks to be erected at Norwich at a cost of some £200,000. When, on account of sanitary deficiencies, the existing barracks were condemned a representative committee of the leading citizens purchased twenty acres of ground as a site for new military headquarters.

THE York Corporation Health Committee, acting upon the advice of Dr. E. M. Smith, their Medical Officer of Health, are asking the Education Committee to discourage the attendance of children under five years of age at the elementary schools in the city.

ON August 24th Colonel Bruce delivered a lecture in the City Hall, Durban, on "Sleeping Sickness," illustrated with lantern slides. The lecture was preceded by a civic reception by the Mayor and Council of the city.

DR. W. H. BEST, medical officer of Lagos, has arrived in England on leave of absence.

MME. DANTCHAKOFF, of Ekaterinoslaw, who was the only lady who took an active part in the recent International Anatomical Congress, presented a report on the functions of the plasmatic cells in the glands of the lower jaw of the rabbit. Dr. Christini gave a very interesting lecture on imbecility, its treatment and cure, and Dr. Barfurt, of Rostock, read his experiments in the regeneration of the peripheric nerves. Michel Sevet, whose tomb was decorated by the International Anatomical Congress, was born in 1511. He was a learned doctor, and followed Karl V. to Germany. In 1531 he published at Hazenau "De Trinitatis Erroribus," which caused a great deal of excitement in the clerical world. He was imprisoned for this, but subsequently released. He went to Paris in 1537, when he made a close study of the circulation of the blood, and in 1540 to Vienna, and there published, in 1553, "Christianismi Restitutio," in which he rejected the doctrine of the Holy Trinity as being fundamentally incorrect. He was imprisoned at Geneva at the request of Calvin as a madman and burnt to death.

Special Correspondence.

[FROM OUR OWN CORRESPONDENT.]

BELFAST.

MATERNITY NURSING IN DERRY.—At the last meeting of the Derry Guardians the question of maternity nursing was under discussion, and some interesting facts came out. Drs. Craig and Cunningham had asked for two additional nurses in their district, and Dr. McCarthy, the Local Government Board inspector reported that there was only one midwife for the two city dispensary districts, and she was over seventy years of age. She had attended 253 cases during the past year. The guardians agreed to appoint one additional nurse, but gave a solemn warning to the doctors that they must not for a moment imagine that they could throw over their responsibilities on the midwives and curtail their own work.

SANITARY CONDITION OF LISBURN.—Thanks in part to the recent outbreak of small-pox in Ulster, some attention is being paid to the sanitary condition of the smaller towns, where great laxity has prevailed. The Lisburn Rural Council has received the report of the Local Government Board inspector on their town, and it cannot be called flattering. It appears that there is no systematic inspection of the meat and milk supplies. Two years ago the water supply was reported as insufficient, and nothing has yet been done to increase it. The sewerage in some parts is most defective, the common lodging-houses are not inspected, there is no disinfecting apparatus, and the Infectious Diseases Act has not been adopted.

Correspondence.

THE CANCER PROBLEM.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—You did me the honour to insert in the *Medical Press and Circular* of July 26th a suggestion and hypothesis bearing on the prevention of the evolution of cancer.

I will not now repeat the general argument on which the hypothesis was based, but simply give an illustration of the biological method.

A graft, say, of a large, sweet, well-flavoured apple, is grafted on the hardy trunk of a crab-apple tree. The result is that the future tree which grows from the little sprig has the character and qualities of the finer tree from which the sprig was cut. This difference of quality, during the future life of the tree, affects and modifies all the tissues; the chemistry of the bioplasm, the rate of growth, &c., are all affected.

Darwin's magnificent, "Provisional Hypothesis Pangenesis" is now, as far as these "gemmules" are involved, discarded; we now, in place of the "gemmules," view

the ultimate modes or motions of "matter" as orderly systems of revolving "electrosis."

But whether through "gemmules" or "electrosis" the little twig of grafted apple stem has imparted a mode, or "motion," or energy to the whole future tree—has modified its growth even to the profounder energies and powers of the seed.

Might we not modify and divert the evolutionary energies of growth which, at the cessation of the menstrual period, find their expression in an exuberance of epithelial, &c., growth—cancer?

Virchow taught us that "every diseased structure has a physiological prototype."

In view of these facts and analogies, would it not be a justifiable experiment to graft into the skin of women who are developing, and passing on to cancer cells, the ovary, say, of a sheep? Might it not restore the balance of the evolutionary energies? Might it not to some degree restore the balance of that cell metabolism which obtained in the pre-cancer periods, prior to the cessation of the great universal monthly functions?

My suggestion is but an approximative hypothesis. I crave the shelter of Herschel, who says (Prel. Dis., par. 208), "Now, are we to be deterred from framing hypotheses and constructing theories because we meet with . . . dilemmas, and find ourselves frequently beyond our depth? Undoubtedly not." "A well-imagined hypothesis, if it have been suggested by a fair inductive consideration of general laws, can hardly fail at least of enabling us to generalise a step further, and group together several such laws under a more universal expression."

Yours truly,

Plymouth.

WILLIAM H. PEARSE.

AN ANTI-VACCINATION ARGUMENT.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR.—"Fas est ab hoste doceri" was a quotation familiar to most of us "in the days of our youth," and it is sound in the days of our "age." I enclose you a cutting from the *Belfast News Letter* of yesterday of a letter from Mr. Horace Mansell, of St. Michael Street, Tipperary, with which I thoroughly concur as to the reasonable conclusion, why should re-vaccination not be made compulsory in the Land of Services, as it is in Germany and other places *all round*, and not merely for those serving in the Army and Navy and Civil Service? The only reply can be that the Government are afraid of acting on their convictions and protecting the general community as they should.

I am, sir, yours truly,

J. WYBRANTS OLPHERTS.

P.S.—It seems in the public services the employees' "consciences" are of little account.—J.W.O.

Downpatrick, August 26th, 1905.

The letter which our correspondent encloses is as follows:—

"Sir,—I noticed in your issue of the 19th that a Mr. Melville was prosecuted as a vaccination defaulter and fined 20s. and 12s. 6d. costs. Now, I do not propose to enter into an argument as to the merits or demerits of vaccination, but I would like to point out to your readers the fact that doctors are unanimously of the opinion that the protection—such as it is—afforded by vaccination, wears off in a few years, ten at the most. This means that in Belfast there are well over 250,000 people who are just as unprotected (the effects having worn off) as Mr. Melville's unvaccinated child. Yet all these 250,000 "dangers to the community" go about unmolested, while Mr. Melville is prosecuted and fined. Surely a most absurd state of affairs.—Yours, &c.,

"HORACE MANSELL, Honorary Secretary, Irish "Anti-Vaccination League.

"St. Michael Street, Tipperary."

Obituary.

GEORGE FRANKLIN HILLIARD, L.R.C.P.S.ED.,
L.F.P.S.GLASG.

We much regret to record the death of Dr. George Franklin Hilliard, of Bow Road, London, E., which sad event took place last week after a severe operation. Dr. Hilliard was born in 1858, and he was, therefore, only 47 years of age. He took the L.R.C.P. and S. Ed. in 1888, and was medical officer to the Mile End Scattered Homes. His genial and kindly figure will be much missed in Bow and Bromley. He leaves a widow and children to mourn his loss.

LEWIS CHARLES EDWARDS, M.B.EDIN., OF
COVENTRY.

THE death took place last week at South Marine Terrace, Aberystwyth, of Dr. Lewis Charles Edwards, only surviving son of the late Rev. Principal T. C. Edwards, D.D. Deceased, who was thirty-four years of age, was educated at the University College, Aberystwyth, and at Edinburgh University, graduating at the latter place as Bachelor of Medicine in 1896. Five years ago he settled at Coventry, and had built up a successful practice as a medical man at that place. Failing health compelled him to relinquish it, and four months ago he came to Aberystwyth. He leaves a widow and three children.

PROF. HERMANN NOTHNAGEJ.

ANOTHER of the most genial, honest, and philosophic professors of medicine has passed away from the Vienna School of Medicine on the 7th of July, in his 64th year. He suffered from stenocardia, and on the morning of the 6th had to take a cab to his lecture at the Clinic; unusual for him. He performed his task, but seemed weak and exhausted, which he attributed to the unusually long attack. The following day he died. He has a noble history of literature and good work to hand down to posterity, a summary of which would be too long to record here. Although his works cover every department in medicine, neurology was his special subject, in which he delighted to reveal. He was an excellent teacher, enthusiastic, zealous and devoted to his work to the very last, and it may be said of him that he died in active service.

Literature.

GOULD ON WORDS. (a)

THE vagaries of medical writers, and their exceeding ingenuity in the coining of new words, have rendered the production of this dictionary a matter of necessity, if "recent scientific literature" is to be understood of the common folk. It is certainly well that, as the learned lexicographer quotes in the course of a most interesting preface, "dictionary makers" do not require souls, for assuredly if they did, and if they commenced their task with the possession of one, they would have lost it before they reached the end, and if by chance an unusually tough soul were to survive, it would be in such a mangled condition as to be valueless. Still, if the lexicographer needs no soul, surely he needs a conscience, which will prevent him from adding still further atrocities to an already long-suffering language. He must be without a soul to be able to deal with the word "dysmorphosteopalinklasy," but if he possessed a conscience he would not have added the word "laparosalpingoophorectomy," as he would not have stolen the hyphen which formerly saved it from disrepute, nor would "hepaticocholecystost-cholecynstenterostomy" be attributed to a living

(a) A "Dictionary of New Medical Terms, including upwards of 38,000 words, and many useful tables, being a Supplement to An Illustrated Dictionary of Medicine, Biology, and Allied Sciences," based upon recent scientific literature, By George M. Gould, A.M., M.D., Pp. 571. London: Bailliere, Tindall and Cox. 1905. Bound half morocco, price 21s.

author, while "oonoididdibismuthmethylenedicresonate" would be intelligible to any chemist.

However, such words only show the necessity for the appearance of this supplement, and the careful manner in which Dr. Gould has discharged his task. Words are intended to convey ideas, and if this old truism is perverted by the writers of recent "scientific literature" into a statement that ideas serve as the foundation for words, surely the lexicographer is not to be blamed.

ERRORS OF REFRACTION. (a)

THIS little book makes no pretension of treating the subject of refraction *ab initio*. It takes for granted a knowledge of geometrical and physiological optics, and in this we think the author is wise. Mr. Blair deals with all the errors of refraction in a very comprehensive spirit, with instruction, and without pedantry. The subject of squint, though in itself highly technical, is here made very plain and easy to follow. We specially commend the following advice, which quite embodies the most up-to-date opinion on the matter: "A squint not exceeding 15° needs a simple tenotomy of the internal rectus of the squinting eye, with suturing of the conjunctival wound afterwards. One of 20° requires a tenotomy with free division of the subconjunctival tissue. One of 30° a tenotomy of the internal rectus, with an advancement of the external. Lastly one of 35° or 40° needs a free tenotomy of the internal rectus, an advancement of the external rectus, and a tenotomy of the internal rectus of the good eye."

The subject-matter of the whole work is clear, concise, and to the point, and the book ought to prove of high value to the student and general practitioner.

ALCOHOLIC POISONING. (b)

THIS undated *brochure* is apparently an unauthorised translation of Professor von Bunge's "Alcohol vergiftung und Degeneration."

It is well that this remarkable monograph should be rendered available to English students, but we could have wished that it had been possible to have arranged for such editing as would have increased its value to English and American readers.

Professor Bunge with the assistance of over a hundred medical collaborators has obtained particulars regarding the health of more than 1,600 families. He has directed particular attention to the relation of alcoholism and nursing capacity. Carefully compiled statistical tables give the result of his analysis. His conclusions are certainly startling. Professor Bunge is a scientist of world-wide distinction, and he has devoted many years to a study of lactation and the various problems which circle the milk question, but before accepting his conclusions as applicable to this country we would like the matter to be submitted to further investigation. In order that we may faithfully present Professor Bunge's results we quote from this English translation of his work: "The daughter of a drinker is rarely, if ever, able to nurse her children. As a rule, where the father has been a drinker, the daughter loses the power to suckle her children, and the capacity is irrecoverably lost to all future generations. The incapability of nursing is no isolated phenomenon. It is accompanied by other symptoms of degeneration, in particular by a want of power to resist the inroads of disease of all kinds: nervous disorders, tuberculosis, decay of teeth. The children are insufficiently nourished, and so from generation to generation, the work of deterioration goes on, leading at length after endless suffering, to the ultimate decay of the race." This pamphlet is opportune in its appearance, and is full of suggestions, and will we trust do much to stimulate research in this country into the action of alcohol as an etiological factor in the production and transmission of morbid conditions.

(b) "Alcoholic Poisoning and Degeneration." By Prof. G. Bunge, M.D., Ph.D. Pp. 27. London: A. Owen and Co. Price 6d. net.

SANITARY LAW AND PRACTICE. (a)

THIS is a most useful book; though primarily intended for the student, it is probably too ambitious for the average, and is likely to be of much more service to the medical officer of health who may want to be able to look up any point of law with reference to his work.

The fact that the various branches of the subject are treated in separate chapters, and all the relevant sections of various Acts of Parliament are collected, makes it of immense convenience and at the same time pleads powerfully for a codification of the innumerable existing sanitary acts.

The law for each division of the kingdom, where different, is given; consequently, at one time, one is reading English law, at another London or other law; it would be of great advantage to put a marginal note on each page to show to which division the page refers, and at the same time some indication to show where the law is absolute and where only adoptive.

The duties of the health official are well described, the chapters on unsound food and adulteration being particularly interesting, though it is not expedient to use the word "hydatid," for the cystic stage of *tænia solium* in the pig, but to reserve it for that of *T. Echinococcus*. The omissions do not seem to be many or serious; however, in the section on New Streets and Buildings there is no reference to the question of the height of buildings compared with the width of streets—a subject that certainly should not have been omitted. Again, the chapter on Prevention of Epidemic Diseases contains no reference to the Epidemic Diseases Prevention Act; it is true that the medical officer of health will find it of no importance to his work, but he would like to have this stated, or else he may be surprised to some day come across a reference to such an Act, which by its title suggests that it should concern him.

As regards the arrangement of the book there is little to be said. The plan of having the definitions collected at an early stage is excellent, but this should not prevent them being printed in suitable places; for instance, it would be advisable to repeat the definitions of drain and sewer at the beginning of the chapter on the subject. By some oversight, while the Power of Right of Entry and the Public Health (Amendment) Act, 1890, are rightly given in the table of contents as two separate sections, in the body of the book they are printed together.

The illustrations are suitable, but in some—(e.g., Figs. 64, 65, and 66)—it would have been better to have turned them so that the bottom of the picture would have been at the bottom of the page; probably this could have been easily arranged.

But taken as a whole, the authors are to be congratulated on having produced a well-planned and carefully executed book, which should prove of great service to those who are occupied in sanitary work.

ELEMENTARY MICROSCOPY. (b)

THIS is a simple, straightforward, scientific manual for beginners in microscopy. It gives just that practical information and sound, sensible advice which a tyro needs. Lucid descriptions reveal the more important features in the construction of both the simple and compound microscope, and wise suggestions aid in the choice of lens and all accessories. There are also useful chapters on the manipulation of the instrument and methods of mounting. Every medical student is supposed to have a practical knowledge of microscopy, but only too often he works by a mere rule-of-thumb. For these and for all desirous of procuring a working acquaintance with one of the most essential and most delightful means of research we commend this unpretentious but serviceable hand-book.

(b) "Elementary Microscopy." By F. Shillington Scales, F.R.M.S. London: Baillière, Tindall and Cox, 1905. Price 3s. net.

THE BLOOD. (a)

DR. COLE'S book on "The Blood" has now reached its third edition—no little compliment to a worker not attached to a teaching school. There can be no doubt felt by any one who reads this volume that Dr. Cole is an enthusiastic and conscientious student of the changes that occur in the blood in the course of disease; but he suffers from the disabilities inherent in the position in which he finds himself, and consequently a good deal of his information is derived at second-hand. For instance, the account given of the Leishman-Donovan body is mostly a quotation from Leishman's own description, and the section Serum-Diagnosis in Typhoid is almost wholly derived from the papers of others. The author excuses himself for not giving his own opinion as to which method for obtaining the latter is the most convenient by saying that typhoid fever is very infrequent in and about Bournemouth. This is very good for Bournemouth, but we should have expected a special work on the blood to have contained a full and adequate discussion on this question, the importance of which, the author says, "cannot be over-estimated." The positive and negative value of the reaction and the necessary degree of dilution deserve ample treatment, and we are surprised that the author did not avail himself of Dr. Horton-Smith's important Gulstonian Lectures to point out the errors that attach to conclusions drawn from low dilutions. The section on the anæmias is, however, exceedingly good, and the differential chart on pages 184-5 admirably carries out a happy idea. Of the coloured plates it is difficult to speak too highly. We have seen many plates lately showing the different forms of corpuscles, red and white, and the blood-parasites, that we thought it hardly possible to improve on; none, however, can compare with these given by Dr. Cole, which in colouring, definition, and artistic reproduction reach the high-water mark of beauty and fidelity. On the whole, this is a very good book, and we can warmly commend it to the notice of those who wish to bring their acquaintance with blood diagnostic processes to the standard of modern knowledge.

LECTURES ON CLINICAL SURGERY. (b)

We have read through these practical lectures which the author tells us were based upon his notes of lectures delivered to the students in Clinical Surgery, at the Royal Prince Alfred Hospital, Sydney. The lectures are chiefly in connection with Genito-Urinary Diseases, and include such subjects as Strictures, Diseases of the Bladder, the uses of the Cystoscope, Hypertrophy of the Prostate and its removal by the suprapubic and perineal routes, Conservatism in Renal Surgery, Suppression of Urine, the Surgical Aspect of Floating Kidney, and lastly a chapter on Appendicitis. These lectures are not only interesting and instructive, but are most readable, and we hail with pleasure the appearance of such works coming from the pen of Mr. Hinder, an eminent Australian surgeon, who must necessarily have at his disposal any amount of material at the Sydney Hospital to write about, and we hope we may ere long see more from the facile pen of this practical Colonial writer.

COMMON DISEASES OF THE RECTUM AND ANUS. (c)

MR. CECIL LEAF'S "Common Diseases of the Rectum and Anus" is a modest little book with a

(a) "The Blood: How to Examine and Diagnose its Diseases," By Alf ed. C. Cole, M.D., D.Sc., F.R.S.Edin. Third Edition. London: J. and A. Churchill, 1905.

(b) "Lectures on Clinical Surgery." By H. C. Hinder, M.B., M.Ch., Honorary Surgeon, Royal Prince Alfred Hospital, Joint Lecturer on Clinical Surgery, University of Sydney, N.S.W. Illustrations plain and coloured, 50; pp 286. Price 12s. 6d. London: Baillière, Tindall and Cox, 1905.

(c) "The Diagnosis and Treatment of some of the Common Diseases of the Rectum and Anus." By Cecil H. Leaf, M.A., M.B. (Cantab.), F.R.C.S. (Eng.), Surgeon to the Cancer Hospital. London: E. H. Blakeley, 1905. Price, 3s. 6d.

modest little aim. It is only to serve as an introduction to the study of some of the excellent text-books on rectal diseases and to help medical practitioners in diagnosing and treating the maladies with which it deals. Little need be said, therefore, by way of criticism; we notice many omissions, but these are excusable on account of the limited scope of the work. We should have thought the chapter on pruritus ani might have been amplified, and a more extended list of alternative treatments given for this troublesome affection. Notice at least might have been given of Sir Charles Ball's operation. We should be inclined to object to the use of the word "hypertrophied" in an anatomical description of a normal structure such as the internal sphincter; the term should be reserved for increase in the natural size of the part due to the action of an unusual cause. We think that the author generally fulfils the object at which he aims; but that is not saying more than that his little book contains about the same amount of information on diseases of the rectum and anus as is to be found in any standard work on general surgery.

Medical News.

Grocer's Unfortunate Mistake.

THE Manchester County Coroner (Mr. J. F. Price) held an inquiry on the 23rd inst. concerning the death of a Gorton woman, aged fifty-five, the wife of a watchmaker. It was stated that on Monday last she went to the grocer's shop of Mr. Charles Andrews, to buy some castor oil. In mistake she was served with camphorated oil, and after drinking this she was taken ill and died. The husband of deceased told the coroner that just after his wife had drunk the oil Mr. Andrews came running into the house and asked if she had taken the stuff. When told she had, he replied that he had given her the wrong oil, but added that it would do her no harm. She died shortly afterwards. A verdict of death from misadventure was returned.

The Cerebro-Spinal Meningitis Scare.

In order to allay public alarm over the supposed spread of what is known commonly as "spotted fever," the Local Government Board issued a circular to borough councils and other sanitary authorities of the United Kingdom on Saturday, stating that the disease is not more prevalent here now than it has been from time to time during the past quarter of a century. Though there is at present no unusual spread of the disease in this country, the Board consider it advisable that sanitary authorities should be on the alert against it. The Board also intimate that they are prepared to consider applications from authorities desiring of making the notification of this disease compulsory by extending the Infectious Diseases (Notification) Act 1889 to it for a time.

Data for Determining Physical Deterioration.

THROUGHOUT the Eastern Command the children attending the military schools are being subjected to a medical examination. The senior medical officer at each garrison has to make an examination of the children, whose height, weight, and chest measurement are taken. An average for each age is then prepared, and is forwarded to the War Office. This examination is to be made annual with a view to obtaining some check as to the physical improvement or deterioration of the children.

Proposed Legislative Control over Early Marriages.

DR. J. J. CLARKE, the Medical Officer of Health for Walthamstow, in his annual report just circulated, recommends that the marriage of persons of immature years, and with no knowledge of the responsibility or duty of parenthood, should be prevented by Act of Parliament. First among the main factors producing a high infantile death-rate Dr. Clarke places early marriages, accompanied by ignorance of parents, poverty, and artificial feeding of babies.

Notices to Correspondents, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

DEATH CAUSED BY YEW LEAVES.

Referring to the annotation on this subject in our last impression, a correspondent writes:—"You say in your comments on the death of an inmate of an asylum from eating leaves of the yew-tree, that you would be glad to hear of any other cases known to your readers. So far as the human being is concerned I know of no case of poisoning, as none but a lunatic would be likely to consume these leaves, but I know of several instances of death in cattle from eating the leaves of the yew, and on my own property a fence of barbed wire has had to be placed round a large tree, in consequence of the loss of cattle from nibbling its leaves. Of course this does not prove that what would be fatal to beast would be so to men, but it at least confirms as a fact the alleged toxic qualities of the yew."

R. S. WILSON.—There are so many good medical dictionaries that it is almost invidious to recommend one more than another. Gould's Illustrated Dictionary of Medicine, Surgery, and Allied Sciences is the most comprehensive, and contains some thousands more words than any other, but if your requirements are more modest and you only need one with words in common use, with the minimum of description, there is the Student's Medical Dictionary published by Mr. Lewis at 7s. 6d., or a still smaller one for the pocket by Messrs. Baillière, Tindall and Cox at 3s.

D. P. H.—It has been shown that old milk is never quite wholesome even kept at a temperature of 50 deg. F., since, though the bacteria which produce curdling, do not develop abundantly, many other undesirable species grow day after day.

DR. DE P.—We think most medical journals get a fair amount of translations sent in, and these are not very highly paid unless of exceptional interest. We return your MS. with thanks.

M. A. (Salop).—The minimum active dose by mouth of tuberculin is 0.075 min. given on an empty stomach in keratin coated capsules, with a little sodium bicarbonate to neutralise gastric acidity.

OPTICS.—There is a large work which would meet all your requirements—"The Ophthalmic Year Book," by Dr. Edward Jackson. It contains even more information on your subject than the exhaustive *Jahresbericht* of Nagel.

L. S. A.—Our Students' Number, shortly to be issued, will contain all information necessary for students intending to join one or other of the various medical colleges.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, AUGUST 30th.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—5 p.m. Dr. Russell; Aphasia.

THURSDAY, AUGUST 31st.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—4 p.m. Mr. Armour: Surgical Cases.

FRIDAY, SEPTEMBER 1st.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—5 p.m. Dr. Abraham: Cases of Skin Disease.

Vacancies.

Metropolitan Water Board.—

Laboratory Assistant.

A Senior Chemical Assistant. Salary £300 per annum.

A Senior Bacteriological Assistant. Salary £300 per annum.

A Junior Chemical Assistant. Salary £175 per annum.

A Junior Bacteriological Assistant. Salary £175 per annum.

Two Laboratory Assistants. Salary £175 each, per annum.

Applications to A. B. Pilling, Clerk of the Board, Savoy Court, Strand, W.C.

The Municipality of the Town of Singapore, Straits Settlements.—

Assistant Municipal Health Officer. Salary £400 per annum.

Applications to C. C. Lindsay, Esq., M.Inst.C.E., 180 Hope Street, Glasgow.

County Borough of Tynemouth.—Medical Officer of Health. Salary

£300 per annum. Applications to E. B. Sharpley, Town Clerk,

Town Hall, Tynemouth.

Hospital for Sick Children, Newcastle-on-Tyne.—Male Resident Medical

Officer. Salary £100 per annum, with board, lodging and laundry.

Applications to Alf. E. Birch, Secretary, Secretary's Office, Hospital for Sick Children, City Road, Newcastle-on-Tyne.

County Lunatic Asylum, Lancaster.—Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

The University of Melbourne.—Professor of Anatomy. Salary £900 per annum. Applications to the Agent-General for Victoria, 142 Queen Victoria Street, London, E.C.

Lanark District Asylum.—Third Assistant Medical Officer. Salary £120 per annum, with fees, &c. Applications to Neil T. Kerr, Medical Superintendent. (See Advt.)

Appointments.

KIDD, MARY, M.B.Lond., Junior Resident Medical Officer to the Canning Town Medical Mission, London, E.

SKRIMSHIRE, C. P. M.R.C.S.Eng., L.S.A., Certifying Surgeon under the Factory and Workshop Act for the Blaenavon District of the county of Monmouth.

THOMPSON, ALEXANDER DET, M.B., Ch.B.Glasg., Senior Assistant Medical Officer to the Mounmouthshire Asylum, Abergavenny.

Births.

ANDERSON.—On August 19th, at Grinshill, near Shrewsbury, the wife of Frederick T. Anderson, M.D., of a daughter.

BARRETT.—On August 23rd, at 56 Manor Road, London, the wife of Sidney Edward Barrett, M.B., of a son.

MELDON.—On August 21st, at 123, Morehampton Road, Dublin, the wife of Dr. Pugin Meldon, of a daughter.

PATERSON.—On August 23rd, at Stirling Lodge, Farnborough, Hants, the wife of Charles E. Paterson, M.D., of a daughter.

POCOCK.—On August 22nd, at Beaconsfield, Bucks, the wife of A. R. G. Pooock, M.D.Lond., of a son.

Marriage.

DENYER-WILSON.—On August 23rd, at Holy Trinity Church, Kendal, Stanley Edward Denyer, O.M.G., M.A., M.D.Cantab., second son of Alfred Denyer, St. John's Lodge, Eastbourne, to Sarah Irene, daughter of Forster Wilson, Monument House, Kendal.

Deaths.

ADAMS.—On July 29th, at Winnipeg, Francis George Adams, aged 36, third son of Dr. James Adams, of Denmark Villas, Hove.

LINDSAY-WHITE.—On August 18th, at 3 Southfield Road, Bedford Park, W., Emilie Frances, beloved wife of Percival Lindsay-White, and third daughter of the late Dr. R. St. John Lyon, Dalkey.

MUDD.—On August 28th, at Chichester, Frederick Charles Mudd, M.R.C.S., L.S.A., son of the late William Mudd, M.D., of Hadleigh, S.folk, aged 65 years.

OPERATIONS—METROPOLITAN HOSPITALS.

Original Communications.

THE MECHANISM OF ANGINA PECTORIS.

By FRANCIS HARE, M.D.,

Consulting Physician Brisbane General Hospital; Visiting Physician Diamantina Hospital for Chronic Diseases, Brisbane.

IN two recent articles (1) it was argued that in their mechanism, the dyspnoea of asthma and the pain of migraine conform to one common principle, in that both these dominant symptoms are essentially vaso-motor and depend upon localised vascular distension due to localised vaso-dilation, compensated and intensified by widespread peripheral vaso-constriction. In the present article it will be argued that many cases of angina pectoris depend essentially upon a similar vaso-motor mechanism; that there is a widespread peripheral vaso-constriction, compensating and intensifying a localised vaso-dilation; and that the resulting localised vascular distension is the proximate factor of the dominant symptom, namely, the distinctive breast-pang or cardiac and radiating pain.

In both asthma and migraine the localised vaso-dilation is well recognised by those who accept a vaso-motor explanation of these paroxysms. The correlative vaso-constriction, on the other hand has received but scant notice from a few, and by most of those few has been seemingly regarded as incidental, not essential. Angina, however, stands differently in these respects. That peripheral vaso-constriction occurs in many cases is freely admitted; while the correlative localised vaso-dilation has been, so far as I can discover, completely ignored, if not unsuspected. And yet all the circumstantial evidence which can be brought to bear on the subject tends to the view that the mechanism of angina in many cases runs a strict parallel with the mechanism of asthma and migraine.

Nothnagel recorded a series of cases which tend to show that a sudden increase of tension in the peripheral arteries due to a cause acting upon the body from without is capable in some persons of giving rise to phenomena approaching those of a paroxysm of angina pectoris. . . The earliest and most conspicuous symptoms of the paroxysm . . . were coldness and pallor with numbness and stiffness of the limbs; the palpitation, feeling of oppression at the chest, the giddiness, the sense of impending death, being all secondary and attributable to the increased efforts which the

heart is called upon to make to overcome the peripheral resistance (2). The coldness and pallor of the limbs is objective evidence of cutaneous vaso-constriction; while in many cases palpitation of the radial and other arteries shows them clearly to be tightened up.

The importance of peripheral vaso-constriction—that is, vaso-constriction in areas other than the seat of pain production—may be inferred from many observations. External cold promotes cutaneous vaso-constriction; and in Nothnagel's cases the attacks were "definitely traceable to external cold" (3). Anstie refers to an extraordinary circumstance reported by Guélineau in the *Gazette des Hopitaux* for 1861, namely, "an epidemic outbreak of angina in which numbers of men belonging to a ship's crew, were simultaneously affected . . . the powerful exciting cause seemed to be the rapid change from a very hot to a very cold climate" (4). The hasty swallowing of cold water will, according to Fagge, induce a paroxysm of angina in some cases (5). As pointed out in the case of asthma, emotion, especially fear, which is commonly associated with cutaneous vaso-constriction, is very apt to determine paroxysms. The same is true of angina: it will be freely admitted that fear is a common excitant of anginal seizures.

Many fevers are associated during their invasion stage with marked cutaneous vaso-constriction; and I have twice known anginal seizures, in persons pre-disposed by previous attacks, precipitated by the onset of fever. In both instances the fever responsible was influenza. But the fever most markedly and constantly associated with cutaneous vaso-constriction is malaria. In the malarial rigor intense vaso-constriction of the skin is an essential feature; and not a few cases are recorded in which the onset of ague precipitated typical anginal seizures. Anstie saw such himself. He also refers to several original and quoted cases in Handfield Jones' "Functional Nervous Diseases," 2nd ed. 1870 (6). And Broadbent mentions a case in which "serious weakness of the heart was left behind for some time" (7).

While it is thus clear that conditions which promote peripheral vaso-constriction are often capable of inducing anginal seizures, it is easy to show that conditions which promote peripheral vaso-dilation are often capable of dispersing anginal seizures. The vaso-dilation may be general, or it may occupy any other area than the seat of pain production. Amyl nitrite inhalation promotes general vaso-dilation; and Lauder Brunton showed that this drug gave instant relief from

the pain of angina in, I think, the majority of cases (8). Nothnagel's cases "were relieved by hot foot-baths and frictions" (9). In several of my cases, the application of hot fomentos to the chest, back, and front gave instantaneous relief; the hotter and more extensive the application the greater the relief. In some the relief so afforded was quite equal to the relief afforded by amyl nitrite. In several cases sipping hot water or any hot fluid has been quite successful.

It is only at the onset of continued fever and during the first stage of the ague paroxysm, that cutaneous vaso-constriction occurs. Generally speaking, "arterial relaxation is the condition of the vessels characteristic of pyrexia" (Broadbent (10). For which reason, in all probability, fever, during its continuance, tends to prevent the recurrence of habitual anginal seizures, just as it does the seizures of habitual migraine (11) and habitual asthma (Trousseau, 12).

Some four years ago Walter Whitehead made the somewhat startling announcement that he had "never failed to treat successfully the most inveterate and severe cases of migraine by the introduction of an ordinary tape seton" (13), such to be worn for a more or less prolonged period. In a work entitled "The Food Factor in Disease" (14)—which is now in private circulation, but which will shortly be published—I have, I think, succeeded in showing that the seton acts in such cases, not through counter-irritation, derivation or revulsion (whatever the exact significance of those terms), but through a mild grade of septic pyrexia. Conformably, I have given cases which show that the average rectal temperature tends to be raised, usually by from $1/5$ to 1° F. through wearing a seton, and that the site of insertion is a matter of complete indifference as far as concerns the relief from migraine. And on a future occasion I hope to show that the occurrence of suppuration is by no means always to be regarded as an unmixed evil. Now in this connection it is interesting to learn that David MacBride (A.D. 1776) permanently cured one, and Erasmus Darwin (A.D. 1796) four cases of angina pectoris by the prolonged use of femoral issues (15).

It is, of course, through causing a tendency to rise in aortic blood-pressure that peripheral vaso-constriction induces anginal paroxysms. Hence conditions other than peripheral vaso-constriction which have a like tendency, may induce paroxysms. Physical exercise at its commencement causes, if violent, a rise in blood-pressure amounting to 20 mm. Hg. (Leonard Hill, 16). This is ascribed to widespread compression of the muscular veins. Whether this be true or not, it is a fact that sudden exertion is prominent amongst the immediate antecedents of anginal seizures. But much depends upon the circumstances which surround the exertion. These are sometimes such as introduce additional cause of rise of blood-pressure. Exposure to cold tends, as already argued, to cause rise of blood-pressure through cutaneous vaso-constriction. A meal, more especially, of course, a heavy meal, is followed by a distinct rise of blood-pressure (George Oliver, 17). And there is no more certain means of inducing a seizure in one who is pre-disposed to angina than hurriedly starting to walk up-hill in the teeth of a strong, cold wind when insufficiently clad and soon after a heavy meal. Indeed, this combination of factors may lead to a very excellent imitation of an anginal

seizure in one who suffers in no other circumstances. The writer has manufactured such a seizure in his own person.

But physical exercise has a double influence on blood-pressure. The initial rise lasts for some fifteen minutes, and then there sets in a fall (Leonard Hill, 18). The fall is ascribed by Clifford Allbutt to general arterial dilation in the extensive muscular layer. In exact conformity with the secondary influence of physical exercise on blood-pressure is the secondary influence of physical exercise on angina. Fagge remarks in this connection:—"It is . . . a curious fact that some persons, after being pulled up by the pain three or four times at the beginning of a walk, will afterwards go on with ease for several miles" (19). This, in my experience, is really the rule, not the exception, as might perhaps be inferred from Fagge's words: of this anyone can assure himself. A lady of 25, who has no organic cardiac disease, suffers from frequent angina. This she can defer indefinitely by regular physical exercise. But sometimes she hurriedly starts to walk when an attack, which in her case commences somewhat insidiously, is impending. The effect is to increase the pain for the first three-quarters of a mile; then the pain rather quickly abates and ceases entirely, *nor does it ever recur during the continuance of the exertion, no matter how severe this may be.* In fact, this patient actually walks off her impending angina, just as others not infrequently walk off impending asthma and impending migraine (20).

It is, of course, unquestioned that many who suffer from angina suffer also from organic heart disease, and that angina, especially when so complicated terminates not rarely in sudden death. But it does not follow, nor has it ever been demonstrated, that the organic lesion is amongst the essential factors of angina. As Fagge says:—"The long duration of the disease in some cases seems inconsistent with the idea that any of the organic lesions . . . can have existed throughout its whole course. Possibly—"—why not probably?—"the paroxysms of angina owe to the lesions in question their severity and their tendency to prove fatal, but do not stand to them in the direct relation of effect to cause" (21). It would seem more reasonable in these complicated cases to ascribe the organic lesions and the anginal seizures to a common factor, namely, prolonged continuous or intermittent rise of blood pressure; nor would this preclude us from assuming that every seizure adds something to the organic damage.

The view suggested by Fagge receives strong support from a consideration of the life history of many cases which present the long observed, but hitherto unexplained, phenomena, of "alternating neuroses." Into this question it is impossible to enter now. But it may be observed that migraine, asthma, and other paroxysmal neuroses have not rarely been observed to alternate, or have completely inverse relationships, with angina throughout the life history of the same patient. I have watched the case of a personal friend for eighteen years. For six years he suffered from irregularly recurring "spasmodic" asthma. At the end of this period he began to suffer from anginal seizures. As these became frequent and severe the asthma gradually became less frequent and severe. Then for three years he suffered

from angina only; and the seizures were typical and intensely severe. At the end of this time the angina ceased absolutely, and in its place he suffered from severe recurrent sick-headaches. Some years later, his sick-headaches having subsided, his angina returned with great severity. It would have been impossible for any physician who saw him during a seizure to speak of "pseudo-angina." The attacks were so violent that the patient usually became sub-conscious, if not unconscious, and were succeeded by symptoms pointing to cardiac weakness. Yet the whole history of the case is, I maintain, incompatible with the view that the angina any more than the asthma or the sick-headaches, depended essentially upon some undiscoverable cardiac lesion.

As long recognised, seizures indistinguishable from typical anginal seizures, may arise through flatulent distension of the stomach. In a case of my own each attack came on shortly after meals; the pain was intense, its character and distribution typical. There seemed to be no peripheral vaso-constriction, and nitrites gave no relief. But instant and complete relief followed gaseous eructation, however brought about. Such cases are apt to be termed pseudo-angina. But for this there seems no adequate justification. By gastric distension the heart is "actually tilted upwards upon itself" (Lauder Brunton). Such would probably cause increased resistance in the aortic outflow; and the result would be a rise of aortic blood-pressure. Thus gastric distension would operate to cause angina in a manner similar to peripheral vaso-constriction. But the obstruction would be differently situated and would consequently require different treatment.

In the view taken in this article, the tendency to rise of blood-pressure which occurs in angina is compensated wholly or in part (as in the parallel cases of migraine and asthma) by an internal vaso-dilation; the vascular distension so determined is the proximate factor of the pain; and the site of the vascular distension is in all probability the coronary area, and quite likely certain adjoining areas.

From observation of cutaneous vaso-constriction, there is a general tendency to infer a like condition in internal vascular areas; and it must be admitted that the physiological principle of compensation implied in correlative areas of vaso-constriction and vaso-dilation, has not been widely applied to the elucidation of pathological problems. For these reasons probably, and from the frequent occurrence of obliterative disease of the coronaries in fatal cases, anginal seizures have been ascribed to vaso-constriction or intermittent spasmodic closure of the coronary vessels with consequent ischæmia of the cardiac muscle (Huchard). But there are objections to this view one of which seems fatal. In the first place, vaso-constriction and ischæmia are not as a rule associated with pain, but with numbness and depressed sensibility; vascular distension is on the contrary a common cause of pain. Secondly, the heart muscle is supposed to be called upon to perform additional work during anginal seizures; and all other muscles so situated have their arterial blood supply increased through vaso-dilation, not diminished through vaso-constriction. Finally, the recent experiments of Schäfer render it highly improbable that the coronary arteries are provided with vaso-motor fibres, either con-

strictive or dilative (21). This conclusion would, of course, preclude both vaso-constriction and active vaso-dilation of the coronaries as a proximate cause of angina. But it would not preclude an intense passive dilation of these vessels. Indeed, an absence of all vaso-constrictive impulses would render the coronary arterial system peculiarly susceptible to any increase in peripheral resistance.

Persistent or frequently recurring strain of the coronaries through passive dilation would amply account for the arterio-sclerotic or obliterative disease so frequently found in these vessels. Vascular distension of the adjacent cardiac plexus would account for the radiating pain in anginal seizures. And the prolonged recurrence of vascular distension in this situation would account for the evidences of neuritis in the cardiac nerves demonstrated by Lancereaux, Peters, and others. Indeed, much evidence could be adduced to show that recurrent vascular distension of nerves and ganglia is the basis of many neuralgias (tic douloureux, sciatica, etc.), and that these ultimately graduate into neuritis.

In migraine, evidence of the localisation of the internal vaso-dilation was found in the relief afforded by compression of the arterial trunks leading to the dilated area. In both migraine and asthma, evidence of the same was found in the relief afforded by the direct application of cold to the dilated area. In angina no such approximately direct means of demonstration is available. But much circumstantial evidence offers itself.

The vascular distension of the coronary and adjoining areas can only be maintained by the driving force of the left ventricle acting against the peripheral resistance. A decrease in the operation of either of these fundamental factors will relieve the vascular distension, and consequently the angina. We have already seen the anginal seizure relieved by decrease of the peripheral resistance, achieved in numerous ways. It remains to show that angina may be relieved by decrease in the driving force of the left ventricle.

Syncope implies decrease in the driving force of the left ventricle; and syncope may be observed in some cases to come to the relief of angina, just as it does at times to the relief of migraine, if not to the relief of asthma. One of my patients suffers at times from syncope as well as from angina. Both varieties of seizure are associated with cutaneous vaso-constriction; and both are promptly relieved by amyl nitrite inhalation. Consequently it is reasonable to believe that the essential difference between them consists in the mode of compensation for the increased peripheral resistance. In the angina the compensation is by vaso-dilation; in the syncope by reduced ventricular force. This view receives further compensation by the fact that on some occasions a partial syncope supervenes on, and supersedes, an anginal seizure.

Again, it is certain that the driving force of the left ventricle depends very largely upon the integrity of the mitral valve. Mitral insufficiency will greatly impair the driving force of the ventricle, and by so much will diminish the probability of areas of vascular distension. Conformably, Broadbent has placed it on record that "the supervention of mitral regurgitation may . . . greatly diminish the liability to attacks in cases of angina" (23). He adds that the future

course of the disease may be entirely changed. The view of the mechanism of angina herein propounded has not, so far as I can discover, been hitherto entertained; this seems amply accounted for by the omission from pathological speculation of the physiological principle of compensation implied in correlative areas of vasoconstriction and vaso-dilation. The view may, of course, be largely—it can hardly be entirely—incorrect. Yet this much may be safely said:—It conforms with the vaso-motor mechanism of those closely-related paroxysmal neurosi, asthma and migraine; it is consistent with the natural history of the disease and with all the means of relief in common use; and it leads directly to new and rational methods of treatment, preventive, palliative, and curative. Consequently it demands the serious consideration of the profession.

French Clinical Lecture.

ON FLUCTUATION. (a)

By PROFESSOR RECLUS, M.D.,
Surgeon to the Paris Hospitals.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

ONE of the difficulties with which beginners are met in practice is to satisfy themselves of the presence of fluctuation, a difficulty from which even experienced practitioners are not exempt. I remember a case in my young days in which my chief, having examined an abscess, confidently declared that fluctuation was present. I carefully followed his instructions as to the mode of examination and paid particular attention to the impressions conveyed thereby, but a few days later I was surprised not to be able to elicit the same phenomena either in a patient with ascites or in one with hydrocele. In both these cases, however, my chief had pronounced the

word "fluctuation." My uncertainty was aggravated when, in discussing a lipoma, he referred to what he called "false fluctuation." I consulted my books, which appeared to me to throw very little light on this point. As you too may have found yourselves confronted with the same kind of hesitation, I have chosen this subject as my theme for to-day.

The principal cause of this misunderstanding is the assumption on the part of the inexperienced that a particular word must needs convey a particular sensation. Now this is not the case, for the word fluctuation applies to many and widely different sensations. It may, therefore, be well if I commence by formulating the following definition "the word fluctuation is applied indifferently to the various sensations that the surgeon perceives in presence of a collection of fluid in the tissues." No doubt it would have been better to give each sensation its special name, but since universal custom has rendered the word fluctuation intangible we must fain employ it, though there is nothing to prevent our studying in detail its many modifications.

1. There is one to which the word fluctuation applies very accurately, in fact the word "undulation" would have been preferable to the former. Unfortunately for nomenclature this variety is quite exceptional. Its production infers the presence of fluid in a large cavity with pliable walls. Such collections only exist in ascites, traumatic serous effusions and certain ossifluent tumours. When we tap such a tumour the eye sees and the hand feels the wave of the fluid which undulates in every direction; the wall of the tumour "floats and trembles to the naked eye" as if a series of small waves were passing beneath it, making it rise and fall.

2. A second kind of fluctuation, even rarer than the preceding, and altogether different therefrom, is the sensation of shock. We only get this in ascites, and for its production there must be a large collection of fluid and the cavity must be well filled, a striking contrast to the preceding conditions. Under these circumstances, when the surgeon gives a sharp tap or flick on one part of the tumour, the other hand, applied flat on the opposite side, immediately perceives a short, sharp shock, the strength of which is directly proportional to the impact. Chassaignac, one of the few authors who endeavoured to classify the sensations of fluctuation, observes that of the various signs, undulation and shock are alone pathognomonic of a collection of fluid in the tissues. The other varieties leave room for doubt, and may even lead one astray, and in any case the sensation must be very clear to justify the diagnosis.

3. A third kind of fluctuation is described as the return shock. It is met with in certain deeply seated collections not readily accessible to the finger; or where the sac containing the liquid lies upon a bone. A peri-pharyngeal abscess is the classical example of this kind. In this case the posterior wall of the pharynx is raised by an exudation between it and the bone. The finger is introduced through the mouth and made to come into sharp contact with the tumour. To begin with, the finger depresses the tumour, but if the finger, suddenly arrested, be met by a return wave we are justified in assuming that the tumour contains fluid. The pus

(a) *Gaz. des Hop.*, March, 1905.

displaced by the examining finger has come into contact with the hard posterior wall of the pharynx which sends it back and it impinges on the finger.

4. A fourth, less known, variety is characterized by a sensation of retreat. This is felt in the big natural cavities, such as the thorax and abdomen, in collections having several "pockets," or with numerous diverticula, in suppurations such as the diffuse phlegmons of the limbs, &c. We press on the tumour, which does not resist; the wall sinks in and the contents go elsewhere. The mechanism is easy to understand; the deep cavities are big and only slightly distended, but the least internal pressure suffices to cause the passage of the contents of the superficial into the more deeply situated pockets. All abscesses communicating by a small opening or into separate cavities are capable of yielding this sensation, and I have twice met with it in cases of suppurative peritonitis; the exudation whereof distended a disused hernial sac. The general symptoms have led us to suspect strangulated hernia, but on the least pressure the voluminous inguinal tumour subsided into the belly.

5. A fifth variety is met with in certain abscesses of the mammae which give the sensation of a trephine opening. The pulp of the exploring finger enters an aperture, usually of narrow dimensions, a fifth of an inch at most in diameter, with a hard, resisting border. Here again you may, on pressure, obtain the sensation of retreat, but if then you seize the whole breast with the other hand and exert compression the finger is, on the contrary, upraised. You understand, I hope, that the liquid—pus in all probability—which has perforated the mammary capsule and has extravasated outside it, is forced back into the original cavity when the finger presses upon it and *per contra* returns to the more superficial situation when the deeper cavity is rendered tense by pressure.

6. A sixth and much more important variety, the one most frequently met with in practice, is altogether distinct from those previously described, *viz.*, fluctuation by seesaw or counterpoise. To appreciate this sensation one finger of the right hand is placed on the tumefaction and a finger of the left hand is also placed thereon, at a greater or less distance according to the size of the tumour. Pressure exerted with the right finger is perceived by the left finger which is raised. *Vice versa* the manœuvre may be repeated by pressing with the finger of the left hand when the right finger will be raised. You see then that it is possible with these two fingers to create a movement of alternative or seesaw counterpoise, which is called fluctuation, although it has nothing in common with the signs already described.

This fluctuation by seesaw or counterpoise may be compared to the form of fluctuation by pinching, thus named by Chassaignac. This can only be obtained in very prominent tumours, such as certain præ-patellar hygromas, hæmarthroses or hydrarthroses and in pedunculated collections, such as cysts of the cord, of the epididymis and of the tunica vaginalis. To obtain it we must seize a segment of the tumour between the thumb and index finger of the hand and another segment between the thumb and index finger of the other hand. When we squeeze with the fingers of one hand we feel

that the fingers of the other hand are separated. This variety, however, hardly amounts to a separate variety, for after all it is only a form of fluctuation by seesaw.

This remark applies equally to the plan adopted in deep-seated suppuration of the limbs. For instance, to obtain the sensation of fluctuation in a sub-muscular abscess of the thigh muscles we apply the palms of both hands flat upon the thigh at some distance one from the other. We press with one hand, and in presence of a deeply seated abscess we soon feel that the other is raised by "a rounded supple body" that projects from beneath. But you will note that this plan after all is only a further application of the seesaw sign, the palms of the hands replacing the pulp of the finger.

The liquid thus shown to be present is usually pus. All phlegmons, glandular abscesses of the limbs, trunk, and head give us this sensation of seesaw as soon as the pus has collected. Blood-containing cavities, hæmatomata, yield a similar sensation as do also the serous cysts. You must not, however, go away with the idea that in every case of collection of blood or pus you will obtain this sensation of seesaw. Not to go farther afield than cysts of the breast, if the cyst happens to be tense and of small dimensions, with a thick wall or covered with a sufficiently thick layer of glandular tissue, the cyst does not fluctuate, there is no seesaw motion, the tumour has a wooden resistance which often leads to its being mistaken for a neoplasm even by experts.

Nevertheless, this seesaw motion remains a very valuable sign. It was especially so in former days when an inopportune incision might determine the death of a patient, when it was all important only to operate on certain data; consequently, the question concerning fluctuation was then regarded by examiners as of capital importance. Though less important nowadays it is absolutely necessary to recognise and distinguish false fluctuations.

You may be aware that when we press with the finger end on certain muscular masses, on certain solid tumours, lipomata, medullary sarcomata, soft lymphadenomata, myxomata, spongy masses of white tumours, &c., a very distinct sensation of fluctuation may be perceived. It has been insinuated that in such a case the error must be due to want of care in the examination, and Chassaignac asserts that with "tact and experience" we ought always to be able to distinguish between true and false fluctuation.

My own opinion is rather in favour of that expressed by Trelat, who was a great master in diagnosis, that such shades of difference are non-existent, and that even experience and tact will not enable us to distinguish between the two since they are practically identical. I myself have seen him make mistakes of this kind and plunge a trocar up to the hilt into a scrotum distended by a soft sarcoma under the impression that it was a hydrocele. Yet, who more than this great teacher possessed the two qualifications indicated by Chassaignac as necessary for the avoidance of error—tact and experience?

Let us take the classical example of the fluctuation of a cold abscess and the false fluctuation of lipoma. Surgeons who pretend to distinguish between the two as often as not go wrong. Palpation gives the same sensation of seesaw fluctuation,

just as precise and distinct in the one case as in the other. If then they manage to arrive at a correct diagnosis between the two conditions it is because they have availed themselves of other concomitant signs: cutaneous thickening, lobulation of the tumour, indolence or pain, or the mode of evolution. The fluctuation urges them to say here there is the liquid, but their judgment intervenes and suggests the idea of a solid tumour, and, it may be unconsciously, modifies their first impression and leads them to describe it as "false" fluctuation.

What a number of stories I could relate to show that the cleverest, the most experienced, the most erudite, make mistakes, and are unable to distinguish between true and false fluctuation. One day Dr. Denonvilliers placed on the table of the Surgical Society a subcutaneous tumour, widely excised on a dead subject. Was it a lipoma or a cold abscess? The surgeons present examined the tumour one after the other, tried to elicit fluctuation, and ultimately half of them opined one way and the other half the contrary. No one was prudent to declare that the problem was one that could not be solved merely by trying to obtain fluctuation.

I have seen an even better example. Thirty years ago a certain surgeon, curator of the Dupuytren Museum, incised a tumour on a patient's forearm which he believed to be a cold abscess. A mass of fat protruded through the opening so that he took it to be a lipoma, and the patient was sent into Broca's service for its complete removal. Broca, who held to the view that it was possible to distinguish between true and false fluctuation, delivered a little lecture on the case to explain to us how his colleague had fallen into error, and he repeated that with tact and experience such errors could be avoided. He then proceeded to free the tumour, when all at once there was a rush of pus that spurted all over him. The lipoma was really a cold abscess covered with a fatty envelope, which the original operator had been too timid to pierce.

In short, gentlemen, fluctuation and false fluctuation are two different words that describe a single sensation, and I will conclude my remarks by repeating my definition that under the term fluctuation we group a number of sensations which, though widely different from each other, reveal to the exploring finger the presence of a collection of fluid in the tissues.

THE PART PLAYED BY SHELL-FISH IN THE INCIDENCE OF TYPHOID FEVER. (a)

By J. T. C. NASH, M.D. EDIN., D.P.H. CANTAB.,
Medical Officer of Health, Southend-on-Sea.

THE writer first quoted from a paper he read before the Epidemiological Society of London in April, 1903, on "The Seasonal Incidence of Typhoid Fever and of Diarrhœa," in which he adduced evidence and arguments in favour of his thesis that "the seasonal incidence of typhoid fever in this country, particularly in well drained towns possessing a wholesome water supply, has a closer relationship with the con-

sumption of infected shell-fish than with any meteorological or geological phenomena." (a)

Since constant publicity has been given to the dangers of polluted shell-fish of all kinds (oysters, cockles, mussels, clams, &c.) during the last two years, there has been a very marked diminution in the amount of typhoid fever, not only in his own district, but in London and elsewhere.

Since June, 1902, Dr. Nash has been almost monthly reporting to the Southend Town Council on the dangers of partly cooked cockles taken from the bed of a creek in an adjoining district, into which creek the sewage effluent of a town of 4,000 inhabitants discharges. He quoted statistics which showed that during the first nine months of 1903 the incidence rate of typhoid fever in his district was only 0.5 per 1,000, as compared with an average incidence rate of 2.0 per 1,000 for the same months in the nine previous years. Seventeen out of the eighteen cases which occurred during this period in 1903 gave a history of shell-fish. From the facts Dr. Nash made the deductions—

1. That in spite of the warnings he gave from time to time there were still some persons who ate polluted shell-fish.
2. That the numbers of such persons had, however, been materially reduced.
3. That apart from polluted shell-fish, typhoid fever would be almost unknown in Southend.

A remarkable outbreak took place among some labourers engaged on a new sea-wall. Most of these labourers were imported, and many of them had not heard anything of the local stir about shell-fish. About 40 per cent. of these men partook of oysters from a source open to pollution. About 60 per cent. did not partake of the shell-fish. Several cases of typhoid fever occurred among the smaller percentage who were indulging in shell-fish. No cases occurred among the larger percentage that did not partake of the shell-fish. Apart from the shell-fish the conditions of environment were common to the whole lot. Personal warning to each gang and the exhibition of printed notices of warning brought the outbreak to an abrupt termination within ten days or so. Prior to this, one navy returning to East Ham for the week-end took up some of the oysters to his friends. About twenty persons in East Ham were said to have eaten the oysters, and nine or ten of these persons (or about 50 per cent.) were stated to have contracted typhoid fever two or three weeks later.

Dr. Nash has been making systematic inquiries into whether shell-fish have been eaten or not in dealing with every case of infectious disease notified since 1902. He was able to show that among 830 cases of other infectious disease notified during the three years 1902, 1903 and 1904, shell-fish had been eaten by less than one person in every hundred. On the other hand, among 149 cases of typhoid fever notified during the same period, no less than 62 per cent. had recently partaken of shell-fish, while a considerable proportion of the remaining 38 per cent. were secondary to shell-fish cases, and therefore indirectly attributable to shell-fish. As a considerable proportion of the cases of "other diseases" were adolescents or adults, and a considerable proportion of the "typhoid fever" cases were

(a) Abstract of Paper read at the Leicester meeting of the British Medical Association.

(a) "Transactions" of the Epidem. Soc., vol. xxii., 1902 & 1903.

children, there was no very material difference in the age incidence of each group.

Dr. Nash then exhibited some diagrams he had constructed to show the diminution of typhoid fever in Southend since Sir Wm. Broadbent's communication to the *British Medical Journal* in 1855 began to put medical men on the "qui vive" as to the causal relationship of oysters from polluted sources. He showed that striking an average for the next ensuing three years there was a remarkable reduction in the incidence of typhoid fever, though no change in sanitary conditions had been effected.

In 1897 the Corporation instituted a house-to-house inspection, and in 1898 a new sewage scheme came into use. A further reduction in typhoid fever was noticeable during the next ensuing three years, but Dr. Nash is inclined to attribute a considerable proportion of this further reduction to an increasing knowledge on the part of the profession and the public as to the dangers of oysters. In spite, however, of sanitary improvements and of a lessened consumption of polluted oysters an undue amount of typhoid fever still prevailed in the borough when the author became Medical Officer of Health in 1901. His inquiries soon made him suspect partially cooked cockles from a polluted source. A definite outbreak in June and July, 1902, enabled him to clearly inculpate and denounce these parboiled cockles which hitherto had been supposed to have had all evil scalded out of them. Dr. Nash's researches in this direction are embodied in a paper in the "Journal" of the Sanitary Institute, vol. xxiii., 1902. In spite of much local opposition he firmly and repeatedly warned the public against eating cockles from polluted or unknown sources. Shortly subsequent to this, the Annual Report of the Medical Officer to the Local Government Board appeared in print embodying the results of experiments made by Dr. Klein on partly-boiled cockles which conclusively demonstrated that the bacillus typhosus could survive the methods of cooking then in use. The local dealers became in time convinced and adopted improved methods, getting the cockles from purer sources and steaming them thoroughly for several minutes.

The sequel has been of the happiest nature. The reduction in the incidence rate in Southend has been one of nearly 90 per cent., while a marked diminution is noticeable in London, where many hundreds of gallons of cockles are consumed yearly. These results are naturally to be viewed with the greatest satisfaction. The large part played by flies in carrying infection during the summer months was then briefly alluded to, and it was incidentally remarked that the original source of the infective material though difficult actually to identify is, nevertheless, easily comprehended when it is remembered that 25 per cent. of typhoid fever convalescents excrete living typhoid bacilli in the urine for weeks or even months after convalescence, as pointed out by Dr. Horton Smith (a) in 1900. The author urges this fact as a reason for treating all typhoid convalescents with urotropin prior to discharge; or, at any rate, that the urine should be examined systematically for typhoid bacilli before con-

sidering or certifying a patient as safe from infection.

HYGIENIC TEACHING AND TRAINING AT SCHOOLS. (a)

By HENRY KENWOOD, M.B., D.P.H.,

Professor of Public Health at University College, London; Medical Officer of Health of Metropolitan Borough of Stoke Newington, &c.

LITTLE apology need be offered for a short paper which deals with a matter of such national importance as that of hygienic training and teaching in schools; for we are all too painfully aware of the large amount of wasted health, energy, and life which results from ignorance and neglect of the laws of health, and which apart from the misery it entails, constitutes a heavy economical loss to the State.

The ignorance among the poor of household management and of the principles of hygiene is responsible in no small measure for their high preventable mortality, their inferior physique, their intemperance, and their poverty. The radical cure for these evils is a suitable hygienic education, moral and material; and we ought not to allow our middle and better classes attending school to "complete their education" without the knowledge of a few important facts of hygiene which can to a great extent determine their future health, happiness, and usefulness.

If it were necessary to make an apology at all, it would be on the grounds that one hears such varying opinions of what the scope of this hygienic instruction should be that it seems desirable still to discuss the subject until the best and most workable scheme has been evolved. What we want is, in the words of the late Sir John Simon, "that education which by model and example, would lead the poorer classes of society to know cleanliness from dirt, decency from grossness, human propriety from brutish self-abandonment . . . an education which would teach them to feel the comfort and profit of sanitary observances, and would apply their instincts of self-preservation to the deliberate avoidance of disease. The need of bodily health as the foundation of sound mental work is recognised, and the training and teaching of children to observe those habits of cleanly decency which are the very basis of a healthy life, and the care for the hygienic environment of the scholar, are grave responsibilities attaching to all those to whom young lives are entrusted."

The school régime must be made to afford every opportunity for healthy bodily development, not only by training the scholars in suitable physical exercises and in encouraging them in a good selection of games, but also by continually presenting an object-lesson of the recognised importance of fresh air, cleanliness, &c. The teacher can do much by example, precept, and personal influence to create a sanitary conscience among the rising generation. To these ends he should enlist as far as possible the co-operation of parents in the home, and he should bring, if possible, his personal influence to bear upon them in certain cases. The training in the observation of sanitary precepts is a form of moral training, and if the home influences are antagonistic to those of the school the home influence will often prevail. A dirty and neglected child indicates the necessity of attempting to do something to improve the parents. The child will often be the medium for this parental education, but sometimes the local sanitary authority may be used with advantage, especially if it has a female health visitor in its employ.

There is, of course, a very wide distinction to be drawn between what the teacher should know and practise and what the scholar should be taught and trained to do; and in drawing up a detailed syllabus for the latter we have only to ask ourselves at every step, Is it essential that he should know this? Is it knowledge which he or she can apply? In my opinion it is a wicked and stupid waste of time to teach scholars

(a) Goulstonian Lectures, 1900.

(a) Abstract of Paper read in the Section of State Medicine at the Leicester Meeting of the British Medical Association, 1905.

under fourteen years of age the structure of the lungs and the mechanism of respiration. In order to impress upon them the importance of fresh air it is sufficient to base the teaching on the results of common experience and a simple experiment with a candle.

It is almost sufficient to impress upon the scholar certain rules upon healthy living and to give reasons for them; and at the same time to train him in hygienic habits while at school. It is often contended that the youth of the scholars and the limited time available, render adequate treatment of so extensive a subject as hygiene impossible. The justness of the contention depends entirely upon what is regarded as adequate. In my judgment of what is adequate the subject could be sufficiently taught at the cost of only one half hour per week during the last two years of compulsory school attendance—always providing that the scholar is receiving the object lessons of hygienic surroundings and practice during the whole of the school age.

I am disposed to believe that whereas from the very commencement of school life the object lessons of a sanitary environment should always be presented to the child, and he should be made to pay regard to the uses of the sanitary apparatus and provisions for his health and comfort, it would be a mistake to carry him beyond this until he reaches the age of twelve, except it be that certain sanitary precepts might figure in his copy books and reading primers. Having reached the age of twelve he should commence to receive definite instruction in domestic and personal hygiene. The teaching at this age must deal only with elementary and practical facts of importance, illustrated by the concrete where possible, and by object lessons, and these must be so clearly presented that they are understood and carry conviction. The teaching must deal with the most simple, the most easily understood, the cheapest and most practicable means of translating sanitary precepts into practice; not losing sight of the fact that it is the positive rather than the negative which must be presented to the scholar.

The conduct demanded of the scholar will constitute the moral training necessary, and the school buildings and fittings should, so far as possible, illustrate all necessary hygienic observances. It will be most valuable if, subsequent to school age at fourteen, those attending higher-grade schools or evening classes continue to have this important subject impressed upon them. But in the whole scheme of teaching hygiene the fact must never be lost sight of, that, from the broadest point of view, it is only the simple and essential laws of health that require to be taught, and that any scheme which aims at more than this will fail to realise the best results. I have found by considerable personal experience that it is most valuable in enabling the teacher to insure that he has been understood by those he is teaching, if, at the end of each of his practical lessons, he questions some of the pupils and invites questions from them. The aim, therefore, should be to instil these elementary principles of hygiene which relate to the person and the home.

The matters on which the children should be instructed are:—

The importance of and the way to secure—

- (a) Fresh air.
- (b) Cleanliness of surroundings.
- (c) Cleanliness of person (body, teeth, hair).
- (d) Cleanliness of habits (spitting, &c.).
- (e) Bodily functions (regularity of bowels, &c.).
- (f) Suitable clothing (sufficient protection, woollen garments next to skin, &c.).
- (g) Food (clean utensils, protection from dust and dirt, &c.).
- (h) Temperance in alcohol.

There is much to be said against the negative results of an education in which girls are largely separated from domestic influences and experience during the most impressionable years of life, and there is no doubt that the elementary facts of cooking and infant-rearing should be taught to every female child, and there should be a kitchen and a workroom in connection with every

girls' department. Girls should therefore be taught in addition:—

(i) The selection of food (marketing and elementary cooking, the preparation of simple dishes by the simplest means).

(j) How to feed and manage babies.

This matter should be taught conversationally and in a homely way, avoiding all technical and scientific terms and illustrated by facts and objects which fall within the range of family life. As local conditions should to some extent determine the kind of instruction and advice given, the teaching should largely be impressed upon the scholars by local references, &c. For this and other reasons it seems undesirable to demand any book-learning of the scholar.

The child learns best from one of his school-teachers, who, moreover, has training and experience in teaching children; and these considerations, added to the fact that a special teacher for this subject is apt to exceed the simple requirements of the scholar, cause me to feel very strongly that the professional lecturer on hygiene should be excluded from schools, although he is a *sine qua non* for teaching and training the teachers in training colleges, and perhaps for advanced pupils attending continuation classes.

Few things more impress themselves upon the scholar than when one of their number is singled out for some special duty. It would, therefore, be a most telling means to our end if one scholar in each class-room were constituted the sanitary monitor for the week. It would be his duty, during his week of office, to see that the ventilators were open, that the class-room was well flushed with fresh air upon every available opportunity, that cleanliness obtained, that dust did not accumulate, and that all sanitary requirements were observed in the use of sanitary conveniences provided.

There should also be more supervision and control over the scholars in the playground. They should not be allowed to run wild. More in the direction of character formation and moral training can be done by effective supervision and control in the playgrounds than in the class-room.

Special Articles.

EARLY HISTORY OF THE MEDICAL PROFESSION AND OF HOSPITALS.—III.

REGULATIONS OF THE HOSPITALS IN THE MIDDLE AGES.

ORDINARILY, attendants and nurses, after a probation of definite time to test their abilities for this function, were required to dedicate themselves with spiritual vows, in order to exalt the dignity of the avocation, although hospital goods were administered by the more practical laity.

A rigid ordinance of the Brussels hospital interdicted access to its benefactions to any diseased person able to procure a livelihood by personal effort, or through the aid of others. The original and thoroughly religious character of these charitable asylums may be gathered from a requirement that each applicant should, similar to postulants of monastic chapters, solemnly confess and abandon his entire possessions. If the invalid was restored to health, he could withdraw and receive everything back again, and as a salutary concession it was ordained whatever remained over the costs and charges incident to medical care of such inmate, by testamentary disposition, might be willed at pleasure after death; but in case the person died intestate, the institution inherited his property to the exclusion of all heirs.

Identical with the Jerusalem hospital regulations of 1181 patients were to receive three times each week fresh meat, and if sanitary economy demanded, other food was freely provided. Women in pregnancy and foundlings were admitted, although under such scrutinising restrictions as tended to prevent the entrance of disreputable persons. In the Brussels hospital, entrants upon their reception formally donated earthly goods to the eleemosynary corporation in perpetuity,

together with the legal rights which they had possessed, and professing an entire abjuration of civil society, assumed the clerical costume of brown or gray. No married person was admissible, and all trades or secular occupations were formally interdicted, and no one without imperative reasons was allowed to descend into the city. In the year 1341, an asylum partaking of the nature of an hospital was erected in London, for impoverished and aged goldsmiths, out of the public moneys and by charity.

LEPROSY.

Of all afflictions entailing the severest misery during the Middle Ages, and necessitating a sagacious economy, both of medicine and legislation, leprosy was pre-eminently the worst. This dread disease, in its worst form, was fully known to professors of the curative art in the last days of declining Rome, and recognised as difficult of treatment. From the application of simple cosmetics to heal cutaneous discolouration preceding graver types of this disintegrating infirmity, to severer methods of emasculation, the entire range of medicaments and surgery was unsuccessfully attempted. The foundation of this abhorrent treatment appears to have originated in a professional asseveration that eunuchs and women were exempt from the disease—a notion maintained by the Arabic scholar, Athelard, in the twelfth century. Although leprosy seemingly assumed not the importance of an infectious disorder, nor became sufficiently extended among the nations of Western Europe to merit serious attempts at repression prior to the vast movement eastward and the reflex action of the Crusades, there can be no doubt of its existence in an aggravated form, dormant or confined to isolated invalids in the Occident, long before the middle of the eleventh century. Legislative enactments in the year 757, by Pepin, Frankish ruler, forbidding by rescript conjugal relations between a leper and a healthy woman, and the enforcement by Charlemagne thirty years later of sequestration against this terrible malady, interdicting contact with robust people, attest the full knowledge and dread of this disease among the early Teutonic races.

Crusaders, unquestionably provoked contagious diseases, on account of which the Levant for ages had been celebrated. Some of these were mainly generated in the West by infected vessels, dissolute armies, filthy bands of pilgrims, returning from the Orient. Leprosy, with other malignant disorders, engendered by unchecked licence, excessive indifference to sanitary rules, and almost total indifference to civil precautions, was spread throughout Europe as a vast epidemic anterior to the year 1179, to the rapid extension of which the criminal use by several of the same baths, when publicly established in the West, largely contributed. In some portions of Europe, however, medical practitioners, freely advised bacon as a sovereign remedy against the disease of leprosy, when, indeed, paupers were exposed to infection from tainted bathing water used by lepers, and at a time when bleeding and use of the bath, as anciently prescribed, were rendered doubly dangerous by common diet of pork, urged as infallible cures. In general, this excellent sanitary system of bodily lotion was regarded graciously by mediæval chroniclists. The waters near Naples, mineral springs at Bath, England, and at Arles, which cured gout, were especially famous. Frederick I. of Germany freely adopted this remedy by advice of his surgeons. It was apparently inevitable to prevent serious results from repeated use of identical water by filthy vagrants and leprous bathers which, combined with greed for pork as a standard diet, aggravated the types of epidemic eruptions. This meat was regarded by pilgrims as a great delicacy in their distressed famishing peregrinations to Palestine, and a mediæval romancer relates, with gleeful melody, how Richard the Lion-hearted, demanded bacon when prostrated with fever in the East, and in the absence of the real was given a generous cut of a boiled Saracen. Upon discovering the substitution he admitted that Turkish flesh was of finer flavour than swine. Mediæval annalists show the presence of this infirmity among the higher clergy and

prelates, long anterior to its alleged introduction from the Orient.

Isolated houses, distant from the abodes and settlements of men, remote from highways of travel, were constructed to receive pestifers and inoculates, obliged to repair thither voluntarily or by force. In the year 1179, the third Lateran Council decreed that lepers should have private chapels and cemeteries, although the City of London, as early as the year 1118, established a Leprosarium for absolute sequestration of such patients. Knights of the Order of St. John, in the different countries of Europe, had consigned to their care and especial attention eighteen thousand lepers. These infects were forbidden entrance to towns and villages, and required to avoid possible contact with the healthy for fear of propagating the hideous malady; and to make such rule efficient they were obliged to carry a bell to sound an alarm upon the approach of travellers. Quarantine, in modern times, doubtless is executed upon more exact principles of science; but it has never been as inflexibly maintained, both by civil and canonical law as during the Middle Ages. Churches and cemeteries were formally set aside for exclusive use of these afflicted beings, and to the world of life and happiness around them they were as thoroughly dead as though sheltered beneath an eternal tomb. In the time of Louis VIII. of France, this disease had made such rapid progress in its sinister movements that at his death, in the year 1225, he bequeathed a sum of money to each of the 2,000 lazarettos in actual existence in his kingdom at this period—a figure still undiminished at the middle of the fifteenth century.

OTHER PESTILENCES.

Disregard of sanitary rules, woollen clothing perhaps, and a limited supply of linen vestments worn by the mediæval populace, prelates and beggars, dwellings of defective construction, doubtless aided in propagating the frightful calamities of pestilence. A more malignant cause was the arrangement of private houses and public structures, alike erected upon the principle of resisting armed aggression and successfully defending them through prolonged sieges. In these, contiguous to the principal edifice and part of it, were immense reservoirs constantly filled with water, and magazines stored with provisions. This fluid, after the lapse of time under confinement, reached absolute putrefaction; and when the germs of disease began to spread among the countries of Europe, its progress was accelerated by such filth which developed these seeds into pestilential bloom. Under the stress of defective regulations it was impossible systematically to bury the rapidly increasing dead, or prevent infection. In the sixth century, when a frightful pustular malady racked with mortality the metropolis of the Eastern Empire, destroying nearly ten thousand citizens daily, none could be found willing to bury or cremate decaying bodies. At intervals during the Middle Ages, with greater or less frequency, maladies of mortal infection suddenly appeared, against which medical and sanitary knowledge of the time was utterly impotent.

France.

PARIS, September 2nd, 1905.

THE THERAPEUTICS OF COLLARGOL.

SINCE Credé, of Dresden, introduced in 1897 colloidal silver into therapeutics, the applications of the drug have been varied as well as numerous. It is used sometimes as an ointment (15 per cent.) or injected into the veins in solution (5 per cent.) at the dose of one drachm for the adult, and half that amount for children. It has also been given in pills ($\frac{1}{5}$ to $\frac{1}{2}$ gr.), in a mixture (2 to 6 grs. in the twenty-four hours), and as a suppository (2 to 6 grs.). Dr. Breton of Dijon, who has made a study of collargol, publishes a series of cases in which the drug formed the principal treatment.

ERYSIPELAS OF THE FACE.

Several cases of this affection were treated by applications of an ointment of collargol at 15 per cent., and the result was very rapid without any complication.

The dermatitis was immediately arrested and fever fell suddenly. All the patients made a rapid recovery.

TYPHOID FEVER.

Two cases of the gravest form, death being imminent, were treated by injection into the veins of a 2 per cent. solution. The injections were repeated daily at the dose of one drachm. Both patients recovered against all hope, baths, injections of lemon, caffeine, camphorated oil having been tried with no improvement.

PUERPERAL INFECTION.

Four cases of puerperal fever of a very grave type were treated by extensive frictions of the ointment (15 per cent.) over the hypogastric region, while the uterus was swept out twice daily with absorbent wool covered with the same ointment. All the patients made a good recovery.

PHLEBITIS.

All the cases of phlebitis that came under his notice were treated by rubbing the whole of the limb with collargol ointment and afterwards enveloping it in cotton wool. Fever was never very high and resolution took place in from 15 to 18 days.

PHTHISIS.

Dr. Breton tried collargol in pulmonary tuberculosis. The patients were in the third stage of the disease, with large vomicae. Intravenous injections were made and under their influence the temperature lowered, the sweats diminished, the appetite returned, and the general condition improved. Naturally this remission in all those symptoms was only temporary, but life was prolonged for a certain time.

ABSCESS OF TUBERCULOUS GANGLIA.

Several young girls suffering from cervical tuberculous ganglia were treated by injections of a 2 per cent. solution of collargol into the glands. By means of a Pravaz syringe the pus was removed as completely as possible. Then, without withdrawing the needle, the solution was injected until it had filled the cavity, after a few moments a part of the liquid was withdrawn as well as the needle, and the small aperture sealed up with collodion. Every four or five days the injections were repeated, and in a short time the ganglion had disappeared, while—an important point in such cases—no trace of the operation could be observed.

VESICAL INJECTION.

A man, æt. 82, had suffered for a long time from urinary trouble due to hypertrophy of the prostate and for which he was obliged to use the catheter twice a day. The patient when seen by M. Breton was cachectic, feverish, without appetite, and each time he passed the catheter he drew off purulent urine. The bladder had become so irritable that irrigation with simple boiled water was very painful. A weak solution of collargol ($\frac{1}{4}$ per cent.) was injected morning and evening, and soon the suppuration ceased. The patient regained his strength and appears as well as a man of his advanced age could expect. The urine is clear and abundant.

DIGESTIVE TRACT.

One-grain pills of collargol given three or four times a day were found very beneficial in certain gastric febrile affections, and especially in attacks of mucous-membraneous enteritis.

VOMITING IN INFANTS.

Citrate of soda, 1 drachm.
Water, 10 ozs.

A teaspoonful before feeding.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, September 2nd, 1905.

DR. FRANZ HERZOG (*D. Arch. f. Kl. Med.*, 83, 102) relates a case of

TRAUMATIC PARALYSIS CAUSED BY PARTURITION.
A servant-girl æt. 19 was admitted into the Lying-in Klinik, on December 12th. Examination showed a generally contracted flat rachitic pelvis. The labour lasted thirty-five hours, and it was terminated by expression, as the fetal heart-beats were becoming

rhythmical. On the fifth day after labour a cephal-hæmatoma was observed on the right parietal bone of the infant. There was no fever; on the fifth day the patient complained for the first time after the confinement that she could not move her left leg.

On January 4th she was transferred to the "nerve klinik," when she remarked that even when she was in labour on December 12th she could not move her left foot, that it felt numb, but not painful. She could not flex the foot backwards, and the plantar reflex on that side was less than on the sound one. Supination of the foot could be performed but pronation was limited. The movements of the toes were also imperfect, they could not be extended.

After four months the flexor of the leg had caused moderate contracture in consequence of which passive dorsal flexion of the foot was possible only to the extent of the sole forming a right angle with the leg. There was also slight atrophy of the paralysed muscles. In walking the left foot was raised higher than the right, and the act was very difficult. The patellar reflexes were alike on both sides. The right Achilles tendon reflex was present, the left not; plantar reflexes absent on both sides. As regarded disturbance of sensation there was anæsthesia only at the second and third left toes and it extended from the toes to the adjoining part on the back of the foot. The first, fourth, and fifth toes and the distal half of the dorsum of the foot were hypæsthetic.

The patient left the hospital on June 28th, and she could then walk almost without limping; but this was through education of healthy parts rather than from any real improvement in the condition. The left Achilles tendon reflex was still absent.

In traumatic paralysis of this kind (caused by the labour) it was characteristic that the pains or numbness were felt in the limb during labour; that the paralysis was discovered either during labour or shortly afterwards; that it was limited mainly to the peroneal nerve and that the course was tedious and that much improvement or complete recovery was only rare.

The paralysis was attributed to injury to the pelvic nerves from pressure when the relations as to size between the pelvis and the foetal head were unfavourable. The fibres of the peroneal nerve sprang from the lumbar spine and joined the sacral plexus through the lumbo-sacral trunk. This ran diagonally across over the linea terminalis whilst the sacral plexus occupied a protected situation. The lumbo-sacral trunk principally contained fibre for the extensor muscles of the lower part of the leg and the peronei muscles, and besides these only such as played but a small part in the innervation of the flexor muscles. Injury to the lumbo-sacral trunk must always result; therefore the paralysis of the peroneal region, may also affect in a lesser degree the tibial and gluteal regions. In the present case the only sign that the tibial nerve was affected was the absence of the Achilles tendon reflex.

In the majority of such cases of paralysis forceps were employed and in all the labour had been lingering. In the writer's opinion there was no causal connection between the use of forceps and the paralysis, it was the prolonged pressure of the head and nothing more that did the mischief. Possibly alcohol, syphilis, or the gravidity itself might be contributory causes.

The course of the paralysis was always lingering, and its prognosis not good; of 30 cases, 4 recovered, 11 improved considerably, and the paralysis persisted in 15.

A TRADE INSURANCE CASE.

Dr. Becker Kreisarzt von Hildesheim, reports an interesting case in the *Aerzt. Sachverstarn Zeit.*. The case was one of sudden death. A man, æt. 65, whilst at work, fell on to a wheelbarrow and hurt himself at the root of the nose and over the eyebrows. At first he went on working, but very shortly severe dyspnoea came on and he got worse, whilst he was being taken to a doctor. About two hours after the accident, and just as he was being taken into a hospital

he died. The autopsy showed no injury to the stem of the neck, no abnormal signs about the muscles, nerves, or great vessels of the neck; but on the other hand a plug of chewing tobacco, 4 cm. in length and 1 cm. in diameter was found lying between the root of the tongue and the epiglottis, there was also swelling of the uvula, strong injection of the fine vessels of the mucous membrane with blood at that spot; swelling and discolouration of the mucous membrane at the entrance of the larynx and dark blue discolouration of the mucous membrane of the fauces, caused by extravasation of blood into the tissues, similar extravasation under the mucous covering of the larynx and of the upper part of the trachea. The cause of death was given as suffocation from a piece of tobacco.

As the widow made application for an allowance from the trade society, the case was gone into more thoroughly. It was proved by witnesses that the deceased had stated that he fell on his larynx (mit den Kehlkopf) and further that a quarter to half an hour later he spat blood and could scarcely speak. The writer being required to give an expert opinion on the matter on behalf of the Imperial Insurance Office, gave the following—that there were two possibilities of a causal connection between the accident and the death.

First, it was quite possible that at the moment when the accident occurred the plug of tobacco in the man's mouth was forced into the œsophagus, that it could not be got up and that it caused death by gradual and intensifying suffocation.

Secondly, the swelling of the soft parts might be directly attributed to the accident and the fact that there was no skin wound was not against such an assumption as that the necktie, collar, &c., might have warded off the sharp force of the blow, or the blow might have driven the larynx violently against the bodies of the cervical vertebræ, whereby lacerations of the vascular network of blood-vessels were caused at the spot.

In the latter case the plug of tobacco would be of no importance and it might be assumed with probability that it got into the deeper part by handling after death.

The Imperial Insurance Office took this view of the case and decided in favour of the widow and ordered the trade society to pay the death money to which she would be entitled and also the pension.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, September 2nd, 1905.

VAPORIN.

This is a mixture Prof. Monti has been using on the children of the "Poliklinik," with reputed success in pertussis and is much praised by other observers. It is composed of the following:—

Naphthalin, 180 grammes.

Camphor ras, 20 grammes.

Olei eucalypt. glob. piceæ, 3 grammes.

This is put in boiling water and the room in which the child is located saturated with the vapour. This is reported to give immediate relief.

NEW DRUGS.

At the Medical Association in Prague, Chodounsky warned practitioners against the use of every drug that was launched on the market nowadays, as many of them were not what they were represented to be. He knew he was "fighting up stream" when he attacked this mania, but he felt it his duty to warn his fellow practitioners against the free use of drugs whose physiological properties were indifferently known.

If the physiological action be unknown let him beware of the toxicological effects.

THE LARYNX IN PARALYSIS AGITANS.

Cisler reported on 14 cases of paralysis agitans, and noticed a condition of the vocal chords not recorded by any other author in eight of them. One or both of the vocal chords were found in or near the middle line or cadaveric position. In his argument on the cause of the phenomenon he came to the conclusion that

the rigidity of the muscles of the larynx overpowered the vocal chords and thus produced the morbid condition met with.

CÆSARIAN SECTION.

Ostreil gave the members of the Association a strange reason for performing the Cæsarian section. The patient had previously had two children, one of them five years ago causing rupture of the uterus with subsequent puerperal conditions and hæmorrhage, which curettage corrected.

On the present occasion Ostreil tells us that the pains commenced but no opening of the uterus took place owing to the soldering of the os. He relieved this atresia, but could not get more dilatation of the uterus than half-a-crown in area. He finally resolved to operate, and performed the Cæsarian section with success to mother and child both of whom are now well.

At the same time he related the history of an extra-uterine conception which he operated on with equal success. It was her third confinement, she had great pain and fainting during the pregnancy and nothing in the uterus, though the movement of the child was visible. Laparotomy was performed and the child found in a sac behind the uterus. Drainage into the uterus completed the recovery. The pregnancy seemed to be either ampullar or tubo-ovarian.

HÆMO-VOLUME METER.

Hynck showed the members how Grawitz's volumeter could be used for macroscopic diagnosis. He fills the capillary end of the tube with a solution of the oxalate of soda; draws the blood through it which is partially absorbed. The capillary is next sealed with wax and the blood allowed to settle. On the top of the salt the erythrocytes collect, over these the leucocytes, and over all the blood plasma. In normal blood the thin layer of leucocytes over the erythrocytes will be only a line, whereas in leucocythæmia it may cover a wide space. The colour of the plasma is of little value, although the quantity of the erythrocytes may be a guide in many morbid conditions.

SINUITIS FRONTALIS.

Honl related the case of a boy, æt. 13, who came to the clinic with a record of meningitis acuta. The frontal sinus was filled with a thick yellow pus and proceeding further with the operation the outer surface of the dura mater in the frontal region was covered with a thick green pus, a litre of which was drawn from the sub-dural space. This pus contained a large number of Pfeiffer's influenza bacilli. The presumption is that the infection from the nose reached the sinus frontalis and thence passed by the sulcus ethmoidalis into the dura mater, where the destruction took place.

RONTGEN RAYS AND LEUCOCYTHÆMIA.

Hynck recorded a series of six cases of leucocythæmia which he had treated successfully with Röntgen rays. In every case both subjective and objective symptoms began to disappear as the treatment advanced, but it may be noted that arsenic and phosphoric acid were prescribed at the same time. He finds that those treated in this manner do not recur so readily as those treated by other means. All of them showed at different stages hyperglobulin with an increased number of erythrocytes.

EXPIRATORY PULSE RETARDATION.

Vanysek criticised the three symptoms of the neurasthenic—viz., expiratory pulse retardation, and orthostatic tachycardia, and the Erb symptom. These three symptoms he said were associated with the centre that regulates the activity of the heart. They are not altogether confined to the neurasthenic, but are met with in convalescence from severe febrile diseases, acute and chronic poisoning such as phosphorus and sulphur and rapidly growing children. The tria cannot therefore be accepted as an infallible diagnostic

THE TREATMENT OF HÆMORRHOIDS.

Dr. Schlacht, who has given the subject long and careful study, has just issued a second edition of his work, "Die Chirurgische Behandlung der Hæmorrhoiden," like all zealous students in the pursuit of

knowledge, complains bitterly of the absence of progress in the treatment of hæmorrhoids since the days of Hippocrates. From the beginning of the Christian era Schlacht tells us of many strange cures for this complaint, but not till 1897 are we acquainted with any change, when Reinbach put forward the theory that hæmorrhoids were a neoplasm of a benign character. The book is well written and can be recommended for its salutary investigation on a subject that has long lain in a state of quiescence. Schlacht closes with a feeling of sadness that so little has been accomplished to alleviate human suffering in such a common complaint.

Operating Theatres.

KING'S COLLEGE HOSPITAL.

HERNIA OF THE BLADDER.—MR. PEYTON BEALE operated on a man, æt. about 30, who had been admitted suffering from what was apparently a right inguinal bubonocoele. When the patient coughed the tumour was observed to be rather more rounded than usual, and of a much firmer consistency than is generally found in an ordinary hernia. After an incision had been made just above the position of the external ring, the cord was as usual drawn up through the wound, and a large lipoma was found adherent to it. At this stage of the operation Mr. Beale remarked that he had observed that hernias of the bladder were very often associated with such a lipoma in connection with the cord. The lipoma was removed and no sac could be discovered. On investigating the inguinal canal it was found to contain an ovoid structure about the size of a walnut, the apex of this was very thin and apparently composed of loose strands of fibrous tissue, but the rest of the structure felt solid when squeezed between the fingers. When this body was pulled down it was seen to continue into the abdominal cavity in the form of a tube. Mr. Beale remarked that it was impossible to say what the structure was, but it certainly had not the appearance or consistency of any part of the bladder. While making traction on this body some of the loose fibres at its apex gave way, and this was followed by the escape of a small quantity of fluid; this disclosed a cavity lined with smooth mucous membrane. It was now evident that the body was a diverticulum of the bladder with hypertrophied walls nearly half an inch thick, but its apex to which the lipoma had been clearly attached was exceedingly thin, the attenuation having evidently been produced by the constant traction of the lipoma extending over a period of some years. The diagnosis was verified by the passage of a solid bougie along the urethra into the bladder. The bladder diverticulum was then ligatured off in the same manner as the mould of the sac is tied up, previous attempts at suturing the opening in it at its apex having failed owing to the thinning out of the structures forming its walls. The wound having been washed out, the inguinal canal was stitched up, leaving just sufficient room for the cord and its covering, and a small gauze drain. The skin wound was then sutured, a gauze drain being left protruding. Mr. Beale said that this was quite a usual condition met with in cases of hernia of the bladder, although these herniæ were much more common in women than in men. A diverticulum of the bladder appearing as a hernia very rarely, he pointed out, had the appearance of the normal bladder, and was commonly opened by the surgeon without his having any suspicion that it might be bladder. As a

rule, no harm resulted from such opening providing the patient was not suffering from cystitis. The thinness of the wall at the apex of the diverticulum was, he thought, remarkable, and it was quite possible that this was due to its having undergone fatty degeneration.

ST. THOMAS'S HOSPITAL.

TWO CASES OF TORSION OF AN OVARIAN CYST.—MR. EDRED CORNER operated on a girl, æt. 17, who had been admitted suffering from what was supposed to be appendicitis. She had had indigestion for some years. Seven months before admission she had an attack of pain in the right iliac fossa, which shot along the right thigh as far as the knee. She was then confined to bed for about a week. Three months before admission she had a similar attack, which lasted ten days. One month before admission, she had a third attack, which was more severe, attended with troublesome vomiting. This kept her in bed a fortnight. The pain was increased on passing water and on defæcation. Menstruation was irregular. On examination after admission there was pain and resistance in the right iliac fossa. *Per rectum*, a mass was felt high up on the right side of the pelvis. Operation was performed three days after admission. McBurney's incision was made over the appendix region. The appendix was long and slightly adherent to a cystic swelling in the pelvis. The appendix was clamped, ligatured, removed, and the stump inverted into the cæcum. The wound was sutured with fine silk. Another incision was made in the median line below the umbilicus in order to explore the cystic swelling in the pelvis. The cyst was about the size of a fist, and connected with the right ovary. When it was delivered it was found that the pedicle was twisted through one complete turn in a direction contrary to the hands of a watch. The cyst was removed and found to contain extravasated blood. The left ovary was also slightly cystic, but it was left. The wound was closed in the ordinary way by three layers. Mr. Corner said that this case was very interesting as illustrating the confusion that may occur between diseases of the appendix and those of the right ovary and uterine appendage. Clinically, he pointed out, the case presented all the features of an ordinary case of appendicitis, and disease of the right ovary was not found until the operation. The appendix, he remarked, was long and adherent to the cyst, so that the patient had undoubtedly suffered from appendicitis, but the twist found in the pedicle of the cyst and the blood which it contained pointed certainly to the cyst being the cause of the attacks of pain and probably also being the indirect cause of the appendicitis. Another feature, he said, was worthy of mention: The torsion of the pedicle of the cyst was not acute and the attacks of pain were undoubtedly due to increments of the twisting which temporarily occluded the vein, hence the extravasation of blood into the cyst; further, at the operation it was noted that the left ovary which was not removed was cystic and the size of a hen's egg. The girl was seen three years later. She was in perfect health and on examination the disease in the left ovary had not progressed.

The second case was that of a nurse, æt. about 40, who was a chronic sufferer from indigestion, and for the last year had had attacks of pain in the right iliac fossa which had kept her in bed during the different attacks from three to fourteen days. Besides these severe attacks she found when helping her patients to

change their position in bed that she had severe pain in the lower part of the abdomen which made her feel very sick and faint and necessitating her lying down for some minutes. On examination there was pain and resistance in the right iliac fossa. *Per vaginam* there was pain and tenderness high up in the right side of the pelvis. The case had been diagnosed as one of appendicitis. The abdomen was opened by displacement of the outer and lower part of the right rectus muscle. The appendix was found to be slightly adherent, but not grossly diseased. It was clamped, ligatured, and removed. A cyst about the size of a hen's egg was found in the right ovary, which, when it was delivered on to the surface of the abdomen, was seen to have a twisted pedicle, and to be full of blood. The cyst was removed and the abdominal wall sutured in the ordinary way. Mr. Corner said that this case was very similar to the one he had first operated upon. In both of them the histories and conditions found at the operations were almost identical. In both cases the primary cause of the trouble was sub-acute or chronic torsion of the pedicle of an ovarian cyst of the right side, which had secondarily caused inflammation of the peritoneum surrounding the appendix and appendicitis. This appendicitis was very different from ordinary cases of that disease for in ordinary cases the inflammation arises from the inside of the appendix, whilst in these two cases the inflammation arose from outside. In this second case, he said, there was one point to which particular attention should be drawn, namely, the sharp and sickening attacks of pain in the lower part of the abdomen, which occurred and recurred whenever any effort, such as lifting a patient, was made. This, he thought, was a point which might be of the greatest use in the diagnosis of future cases and in differentiating between inflammation and torsion of the pedicle in the region under consideration. These two cases emphasised, he considered, the extreme importance of examining the right ovary and appendages in every woman who is operated upon for appendicitis; such a step, he thought, should never be omitted.

Cholera Scare—Germany Alarmed at the Progress of the Disease.

Cholera in Germany appears to be steadily increasing. One death is reported from Hamburg, that of a Russian emigrant. In West Prussia there are now over sixty cases.

Medical Tour in France.

One hundred and fifty British, German, and Danish doctors, taking part in the seventh tour made for the purpose of medical study under the direction of Professor Landouzy, a Member of the Academy of Medicine, arrived at Bagnères-de-Luchon last Friday.

A FINE hospital has been completed at Punta Arenas, a town in the most southerly department of Chile.

A GENERAL hospital, at a cost of 2,191,950 dollars, is in course of erection in the city of Mexico.

THE Army Council has decided to cancel the order directing medical officers returning home at the end of a tour of service abroad to report themselves personally to the Director-General. These officers will in future report themselves to the War Office in writing.

DR. A. WYNTER BLYTH, Medical Officer of Health of Marylebone, in a recent report concerning the health of the borough during July last, states that the death-rate was 12·3, against 16·9, the average in July for the preceding five years. This singularly low rate of mortality is attributed to sunny weather and freedom from epidemics.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5 0s. 0d.; Half Page, £2 10s. 0d.; Quarter Page, £1 5s. 0d.; One-eighth, 12s. 6d. Considerable Reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the Publisher.

Small announcements of Practices, Assistantcies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and Colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, SEPTEMBER 6, 1905.

DROWNING AND ARTIFICIAL RESPIRATION.

THE recent issue in book form of the Report of the Committee appointed by the Medico-Chirurgical Society to inquire into the “Phenomena attending Death by Drowning and the Means of Promoting Resuscitation in the apparently drowned,” calls attention to some important points both in the mechanism of drowning and in the methods of artificial respiration. The Committee, of which Professor Schäfer was chairman, entered into the work with considerable zest, and performed a number of experiments on dogs and men with a view to elucidating the knowledge they were in search of, yet one cannot but be disappointed in reading their report to find that from lack of time, means, or enthusiasm, they did not carry their researches to the point of definite and unchallengeable decision. The phenomena of drowning are still far from being properly understood, and much of the information found in text-books on forensic medicine having been culled solely from post-mortems on drowned bodies is far from satisfactory. There are few medico-legal decisions of greater difficulty than that of saying definitely whether a given body found in a river or in the sea came to its death by drowning or was thrown into the water after death; the point is continually arising in coroners' inquisitions, and it must be admitted that owing to uncertainty as to the signs of drowning, the medical witness is not always in a position to give a categorical opinion. Now it is obvious to anyone who has performed many post-mortems on drowned persons that drowning is far from being a simple, straightforward act. Some persons “go down like a stone”; others gasp and struggle for many minutes. Naturally the post-mortem appearances corresponding to the conditions are vastly different. The Medico-Chirurgical

Committee adopted such artificial methods of drowning the dogs on which they experimented that the conclusions can have but a partial application to the phenomena of drowning in general. The dogs were anaesthetised and their muzzles held under water, conditions necessary enough in obtaining respiratory and blood-pressure tracings, but hardly comparable to those which obtain in reality. Still, some important facts were brought to light. One of the most striking is that drowning in fresh water appears to differ from drowning in sea water in certain particulars. The experimenters were struck by the fact that most of the water inhaled during drowning was found to have disappeared when the post-mortem came to be performed, and the amount of the water taken in was found to be no measure of the rapidity or certainty of death. Respiration at the first shock was suspended, then became violently expiratory, and not until the last stage were deep inspirations taken. Now this water thus inhaled was found to pass rapidly into the blood, so that in only one case did the lungs after death show any increase in specific gravity, and little or no water exuded from the lungs when they were cut into. With sea-water, however, it was found that the quantity of water absorbed into the blood from the lungs was less than in the case of fresh, owing probably to the osmotic force of sea-water being higher than the blood. Another fact elicited was that the amount of froth found in the air passages after drowning in sea-water was greater than after drowning in fresh, but on the other hand this froth was more fluid in consistence when mixed with the former. Thirdly, immersion in sea-water appeared to be less rapid and certainly less fatal than in fresh. In fact, not only was it easier to re-establish respiration after salt-water immersion, but in two instances the animals recovered completely in quite a short time, and seemed but little the worse for their experiences. We now turn to the time during which immersion may last and yet be followed by recovery, and here we find that contrary to certain statements that have been made lately, immersion may last for several minutes (in one case it lasted nearly eight minutes) and yet not prove fatal if artificial respiration be adequately performed after extraction from the water. Early death was found to be due to cardiac failure and was preceded by a rapid fall in blood-pressure, but if the animal outlived this danger it could be saved by artificial respiration, provided that the air could be made to reach the alveoli and through the alveoli the blood. The chief barrier to the entrance and diffusion of air was found to be frothy mucus. This is not necessarily proportionate to the length of submersion, but seems to depend rather on the quantity of mucus secreted and the amount of convulsive respiration that takes place and churns the mucus up into froth. Such froth is more difficult to get rid of when found in the smaller tubes, and consequently the danger of asphyxia is greater under

those circumstances. Moreover, the longer recovery from respiratory obstruction is delayed, the greater is the danger of cardiac failure. From these observations it follows that much of the success of artificial respiration turns on the method employed and manner by which it is carried out, and the Committee made a study of these questions also. They began by renewing the experiments made by the 1862 Committee, which investigated the same subject, that is to say, they performed the movements of artificial respiration on cadavers and measured the amount of air that entered and left the chest. But they soon found this plan highly unsatisfactory, first, because of the difficulty of getting healthy subjects, and, secondly, because of rigor mortis limiting the extent of the movements. In the end they decided to carry out their trials on the living subjects, and to measure the quantity of air exchanged by means of a spirometer. A young man was trained for the purpose—and a trial—not a very exhaustive one it seems—was given to all the known processes of performing artificial respiration. Taking the amount of air pumped during normal respiration as 455 c.c. per respiration and 5,850 c.c. per minute, the Committee found that the Silvester method gave 178 c.c. and 2,280 c.c. respectively, the Marshall Hall 254 c.c. and 3,300 c.c. the Howard 295 c.c. and 4,020 c.c., and that the intermittent pressure over the lower ribs in the prone position was 520 c.c. and 6,760 c.c. Although other factors than mere exchange of air enter into the utility of a method of artificial respiration, the Committee seems satisfied that not only does the last-named ensure the largest exchange, but that it has other advantages which should bring it into more general favour. In using Howard's method there seems to be a distinct danger of rupturing the liver, which is naturally much congested and enlarged in asphyxial conditions.

DEFENDED LAW AND DEFENCELESS MEDICINE.

THE unprotected rights of medical men have long formed a standing complaint in the journals specially devoted to the affairs of that learned profession. In various ways the subject is of national importance, for it strikes deep into the essential well-being of the people. The principle involved is nothing less than the preservation of the health of the nation, first by the provision of duly qualified medical men, and, secondly, by the exclusion of unqualified and therefore dangerous and illegal practitioners of medicine, otherwise quacks and charlatans. The first of the two aims has been amply accomplished by the Medical Acts, administered by the machinery of the General Medical Council. It may be asserted without fear of contradiction that the general standard of medical education and attainment was never at a higher pitch than at the present time. It is, of course, possible that educational methods may in the future undergo a material

alteration and that the consolidation or even unification of medical qualifications may ultimately prevail, but on the whole the existing state of affairs with regard to the safeguarding of the public against incompetent medical practitioners may be regarded as satisfactory. A similar thing, however, cannot be said when we turn to the second of our propositions, and ask whether the community is reasonably protected by the Medical Acts against the evil practices of irregular medical practitioners. There can be but one answer, and that is to be found writ large in the advertisement columns of the lay press. Every conceivable disease from which humanity can suffer may be cured by some proprietary nostrum or by some irregular practitioner or other. These parasites run the gamut of medical and surgical practice, from freckles and eczema to Bright's disease, from electrolysis to such grave surgical procedures as the cure of ruptures, the treatment of fractures and dislocations, and plastic operations about the face. Yet there is none to say them nay, unless their nefarious practices land them in the police court. By gross elementary defects in the Medical Acts no effectual powers are granted for the prosecution of illegal medical practice. Nor is the duty imposed upon the General Medical Council. As readers know, the only available method of procedure against quacks is by a special section of the Apothecaries' Act. The conditions attached thereto, however, are easily evaded. It is quite possible, nevertheless, were the police alive to the necessities of the situation, that a great amount of irregular medical practice might be suppressed by the operations of the ordinary criminal law applying to conspiracy, false pretences, and vagabondage. If the police want to rid a neighbourhood of undesirable persons they can apprehend them for "sleeping out," for having no visible means of subsistence, for loitering and for various other more or less artificial and doubtful offences. Surely the police could find some means of ridding the community of the host of quacks who live upon the misfortunes of their fellows. The police, however, are not likely to take action while medical men treat the protection of their own vital interests with undisguised apathy. A lesson might well be taken from the lawyers, who do nothing by halves when the legal protection of their profession is concerned. The slightest infraction of ordinary legal practice is visited with instant prosecution and heavy penalties. Indeed, so stringent is the protection that a solicitor is not permitted to act without taking out every twelve months a licence to practise. The principle of yearly certificate goes to the root of the matter by insisting on the necessity of regulating and registering properly qualified solicitors as a first step. Only a few days ago a solicitor was fined £31 7s. for practising without having taken out his annual licence. Contrast that state of affairs with the laxity

that permits disqualified medical men to continue practice with impunity and to flaunt that fact in advertisements inserted in the daily newspapers. There is much to say in favour of the yearly licensing of all qualified practitioners. It would confer a reality upon the present imperfect control of the *Register* in the hands of the General Medical Council. As a preliminary step it would be necessary to render registration of qualified medical men compulsory instead of permissive. There can be little doubt that this would be one of the readiest means of providing a sufficient income to the General Medical Council. This change, as a matter of fact, should be one of the earliest of the many reforms needed to put the medical profession in possession of what is nothing more than its just and reasonable heritage, not to mention the enormous national advantage of the legal regulation and protection of medical service throughout the State.

Notes on Current Topics.

The Profits of Milk Adulteration.

THE practice of food adulteration is not likely to be seriously curtailed under existing conditions of detection and punishment. As in the case of betting prosecutions the profits of the calling are so large that the payment of frequent fines is a mere fleabite to the offender. Especially is this true of the adulteration of milk, inasmuch as the fraudulent vendor is actually selling water to his customers at the price of milk. Could that method be extended indefinitely it would result in riches beyond the dreams of avarice. Fortunately, however, the bounds are set in the shape of Food and Drugs inspectors and of police-court prosecutions. Some of the most cruel and heartless of these malpractices are inflicted upon poor law consumers. Last week a man named Judge was convicted at the West Ham police-court of having sold adulterated milk to the local union. He was under contract to supply "genuine unskimmed milk" to the extent of one hundred and forty-eight thousand gallons at 9½d. per gallon. Analysis showed that the milk delivered at the union contained 32 parts per cent. of added water. A simple sum shows that the profit of water sold as milk in this transaction would amount to some £1,800 or £1,900. Well might Martin Judge, of Plaistow, smile as he paid the £5 fine and 14s. costs inflicted by the magistrate. The only adequate punishment would be to make such an offender pay several times over the cost of the damage inflicted in such a breach of contract, and to make imprisonment compulsory after a first offence.

Seaside for Children.

IN his interesting and suggestive Presidential Address at the Sanitary Inspectors' Association, Sir James Crichton-Browne drew attention to the evils of town-life, and pointed out the fallacy which lay in the argument that by concentrating

the population in towns, capable men were brought to the front. If there were any truth in the contention, such production was at the expense of their physical stamina, and probably of their intellectual, too. In providing educational ladders for the people, the rewards went to the precocious and quick-witted, whose energies in many instances rapidly exhausted, whilst children of greater power but of slower development were left at the bottom. The real breeding-ground for the race is in the free and natural liberty of the country, and if the best stock is continually drafted into the towns, sooner or later an inferior product alone will be left for the jaded and unfertile town-folk to draw upon for recruits. For those compulsorily located in towns a sanitary country cottage is the most healthful and restful holiday resort, and for children dwelling in London and populous towns some such change is especially needful. Sir James pointed out the banefulness of the fashionable idea that children in the summer should be taken from an inland town to a seaside one, there to re-enact under similar but slightly changed conditions much the same artificial life as that which they have left. Children, of course, are notoriously impressionable, and they rapidly fall in with the idea that a holiday is a time to be spent in watching nigger-entertainments on the sands, or listening to bands on parades or piers. The holiday provides for the town-child its only real opportunity of acquiring any knowledge of or association with the pleasures of Nature; but for most of them, when the habits of plants and animals, the beauties of flowers, and the secrets of birds and insects might not only be charming, but educating them, their time is prostituted with a round of unhealthy excitements. Real health is to be found not in assimilating the conditions of the holiday to those of the town, but in making them as different as possible.

Soap for Paupers.

THE cleansing action of soap has been known since the far-off days of Pliny. It is interesting to trace the evolution of the art of soap-making through the earlier centuries to the present day, in which latter the manufacture of toilet-soap has become almost a fine art. Happily for those of small means, the efficacy of soap is in no way controlled by its price, for there is nothing like common soft soap for thoroughly emulsifying and carrying away surface dirt. Nevertheless, in spite of the cheapness of soap generally, recruits are not found wanting to join the great army of the unwashed, which has by no means yet become disbanded. The list of preventable diseases caused by neglect, wilful or otherwise, of the first principle of health, cleanliness, is a long one. Practically all the parasitic affections of the skin would be prevented by the regular application of soap and water, which fact impresses itself most forcibly upon those whose duty it is to see and examine large numbers of the poorer classes in the out-patient departments of our great hospitals.

Only a minute percentage of these individuals are really unable to afford one penny for a cake of soap. In the majority of cases their condition is due rather to neglect and indifference than to poverty. If the pauper will not or cannot get soap for himself, then the soap must be brought to him, and we think that the action of the Strand Union Board of Guardians in giving half a bar of soap to every pauper in receipt of outdoor relief worthy of emulation. There is no necessity, of course, for providing scented soap, for a sickly odour of roses does not make a cake of soap more effective, and we confess we are a little surprised to see that another board of guardians has decided, upon the recommendation of the lady doctor in charge, to supply the children in the workhouse schools with *sixpenny* tablets of scented soap instead of the common article. What will the ratepayers say?

Evolution v. Physical Deterioration.

THE much-discussed question of "physical deterioration" has, as of course every reading (and hearing) member of the community knows, recently engrossed a large proportion of the attention of many of our most representative thinkers. It has turned the eyes of the curious and the patriotic towards the sources of enlightenment and assumed revelation offered by the up-to-date editions (and manifold modifications) of the theories of evolution, of natural selection, of survival of the fittest (or unfittest), of heredity, of the influence of environment, of racial character and configuration, and—not to worry the reader further while attempting to hunt the scientific phrase to death—of sunshine and cutaneous pigmentation. One scientific logician contends that, as in the language of the famous clerical poet, "Life's cares are all comforts"—the presence of adverse conditions, in slum life and other, is after all but a blessing in disguise; for it tends to maintain the continuity of the *struggle* which merely calls forth the *actual* powers of the normal hereditary *potentialities* of the individual. According to this twentieth-century edition of optimism, if all such adverse conditions were successfully eliminated by the combined efforts of the philanthropic legislator and the scientific sanitarian, the race would progressively degenerate, and grow less and less resistant to the attacks of disease. In this connection it has been suggested that the chief function of bi-parental reproduction is to maintain the characters which have been fixed by natural selection. The germ cells must possess the most providential capabilities of resisting external influences. Had it not been for the existence of this biological "fact," those groups of germ cells which tended least to degenerate would survive, while those that tended to lapse into the abyss of degeneration would necessarily be soon eliminated. Evolution of the power to resist retrogression in such characters as have been fixed by natural selection started, we are assured, with evolution itself; and this fact undoubtedly accounts for the extreme resisting power of the germ cells which

recent biologists have commented upon. It is admitted that if families continue the struggle of slum existence, they are inevitably eliminated in the course of three generations at the furthest. Those only survive who possess the character and will to work their way quickly out of slum life. And the all-important evolution which has brought man up to his present position, is one of character, of intellect, of moral forces, and of the habits which are consonant with the needs of social life. Evolutionary resistance to disease and alcohol has taken a very secondary, perhaps a negligible part. We only wonder after the contemplation of such exceptional scientific attainment and philosophic contemplation, what proportion of such statements and arguments could be reduced to syllogistic form!

Food Adulteration.

AMONG the many questions which have recently been brought into public prominence by the echoing boom of physical deterioration, is, as a naturally consecutive consequence, that of the food of the labouring classes. The standard of comfort in the home life of the working man has very notably risen of recent years; he and the various members of his family are provided with food of greater variety—larger in quantity, better in quality, and (professedly) more digestible—than were his parents of the past generation. Agricultural labourers then thought themselves fortunate in securing one meat dinner per week. Yet we are assured that our population is degenerating physically all this time! Nature, we know, performs many apparent absurdities, as the history of every age has shown; and would sometimes almost tempt us to think that she occasionally wishes to lower the overweening conceit of man by placing within stimulating range of his vain curiosity certain interesting, and even important problems which his Tantalus-efforts fail to solve. One of the causes suggested to account for our physical deterioration is that what people used to eat in the bygone days was at any rate what it professed to be, while the canned, tinned, potted, and preserved foods of the present day are usually compounded—at least in considerable part—of various somethings a good deal less nourishing than their outlying labels would lead the confiding consumers to believe. A goodly proportion of the tinned foods consumed in England comes, of course, from the great Western Republic, and a somewhat lurid light has just recently been thrown on this subject by a bulletin issued by the State Board of Health of New Hampshire. The publication of this document must be distinctly disconcerting to the digestive memories of readers who have been indulging in the convenient luxury of manufactured foods, for we there find it stated that of the specimens examined, 91 per cent. of the canned fruits, jellies, and jams were adulterated; every sample of lime-juice was adulterated; so were 56 per cent. of the meat products, pressed meats and sausages; 50 per cent. of the cheeses;

and, in general, of 363 samples of food-products scientifically examined no less than 164—or 45 per cent., were found to be liberally adulterated, or widely divergent from the legal standard. In presence of such data the problem of physical deterioration is hardly so very mysterious after all!

A New Anæsthetic.

THOUGH the introduction of chloroform and ether marked one of the greatest and most beneficent revolutions in surgery, there are few surgeons whose hearts will not be gladdened when they are relegated to the limbo of forgotten things, and some simpler, safer, and less distressing drugs take their place. The pharmaceutical field has been carefully searched for new anæsthetics, but in spite of certain agents of minor utility, such as ethyl-chloride, having been unearthed, chloroform and ether are far from being superseded. It seems, however, that scopolamine, an alkaloid of scopolia, which has hitherto been known as a mydriatic and sedative, can be usefully employed for general anæsthesia. Terrier, of Paris, reports that it can be given, preferably in association with morphia, so as to produce insensibility lasting as long as nine hours. The patient during this time appears to be in a profound sleep, but though he can be roused by shaking and shouting, complete insensibility to pain exists. When the effect wears off he wakes as from sleep, has no knowledge of what has occurred—even if an operation has been performed in the interim—and is free from all adverse symptoms. The appetite is unimpaired, and he can enjoy food. The best method of administration is by hypdermic injection—in combination with morphia. One milligramme is injected with a centigramme of morphia four hours before the operation, another similar injection is given two hours later, and a third after one hour more. The only drawback to this ideal method of inducing anæsthesia is that the drug is not always successful, and profuse sweating sometimes follows its use. If these disadvantages could be obviated, scopolamine would seem to have a rare future before it.

Suprarenal Therapeutics.

THE introduction of extracts of the suprarenal glands into the treatment of disease has given the profession a vaso-constrictor which has practically superseded all others. It seems, however, that whereas all preparations of the adrenal bodies are made from the entire gland, the cortical and medullary portions are as different in function and secretion as they are in structure. Vassale and Zanfrognini, two Italian physiologists, have attempted to discover the effect of ablation of the medullary portion of the gland. Using cats for their experiments, they found that such removal led to death with symptoms suggesting that an essential substance had been withdrawn from the economy. This substance would seem to be the secretion of the medulla which they conclude acts as a stimulant leading to contraction of the

unstriated muscle, and also as a ferment regulating certain clinical changes that prevent auto-intoxication. Vassale later was able to show not only that the substance extracted from the medulla of the gland was five times as potent as that from the cortex, but that it exerted a powerful contracting influence over the smooth muscle of the alimentary tract. As the substance is not affected by the gastric secretions, it can be given by the mouth, and in Vassale's hands has proved of great service in the treatment of the atonic gastric and intestinal conditions associated with neurasthenia. Three other writers of the same nationality have now confirmed these observations, and they conclude that though the action is transient, by giving small doses frequently, not only are gastric symptoms much relieved, but that the tone and activity of most of the tissues are likewise raised. The substance is called "paragangline" by its discoverer, but it has not yet found its way to the market in this country.

Influenzal Urethritis.

THE medical practitioner from long experience looks with a suspicious eye on all cases of urethritis, for although there are circumstances under which the urethra becomes inflamed "idiopathically," they form an infinitesimal percentage of the whole. Gonococci or no gonococci, there are few urethral discharges that have not been acquired by venery, and the errant youth seldom finds a sympathetic listener when he pours his story of the proverbial "strain" into the doctor's ear. If, however, he reads the *Deutsche Medizinische Wochenschrift* for July 20th, he will be able in the future to find a fresh and less worn theory to account for his trouble. In that journal Cohn expresses the belief that many cases of urethritis may be due to the influenza bacillus, and he relates an instance from his own practice. The patient had a urethral discharge in which no gonococci were found, but on making cultures from the pus two organisms were obtained—a capsulated bacillus and Pfeiffer's influenzal organism. The disease proved refractory to treatment, and was followed by slight cystitis and epididymitis. In spite of the presence of the capsulative bacillus, Cohn thinks that the influenza bacillus was the etiological factor, both because it occurred in greater numbers, and because an epidemic of influenza broke out soon afterwards. As the patient admitted to coitus several days before the urethritis occurred, a simpler explanation will occur to most people, but Cohn has thought it worth while publishing the case. If his belief be a true one, influenza epidemics will have an added terror for the gilded youth.

Revision of the United States Pharmacopœia.

WITH the first of this month the eighth decennial revision of the United States Pharmacopœia became official, but the work is nearly five years overdue. The last decennial revision took place

in 1890, so that the word "decennial" must be regarded as somewhat of an euphemism. A healthy sign lies in the actual diminution of the number of preparations admitted, the previous 994 being reduced to 958. In all 151 articles have dropped out, and 117 new ones taken their places. The principle adopted by the Convention for the revision seems to have been to place on the list not every drug of any value at all, but only those which are in demand, and though their selections will doubtless be criticised, most men might be able to manage their prescribing with the nine hundred and fifty-eight articles to choose from, without going to unofficial sources. Anti-diphtheritic serum finds a place for the first time, and the two animal products—adrenalin and thyroid extract—admitted, are the first of their kind. Although it was shown at the Brussels Conference in 1902 that it was hopeless at present to attempt an international pharmacopœia, the standards adopted by that Conference with regard to potent drugs have been accepted, the object being that all such preparations may be of uniform strength in civilised countries. The metric system has been adopted in indicating the average dose, followed by the approximate value in ordinary weights and measures in brackets. Even the tablespoon, dessert-spoon, and teaspoon have not yet been ousted from their wonted position, but they have been ordered to contain definite quantities, namely, 16 cc. (or 4 fluid drachms), 8 cc. (or 2 fluid drachms), and 4 cc. (or 1 fluid drachm) respectively. It is noticeable, by the bye, that fluid extract is now spelt in one word.

A Famous Hospital Subject.

THE death is reported from Vienna of Frau Magdalen Gelly, a well-known frequenter of the clinics as a "subject" for operative and other experiments. This remarkable woman was said to be gifted with a high degree of control over her respiratory apparatus whereby she was able to induce in herself a partial anæsthesia, retaining at the same time her consciousness. She was accustomed to allow the surgeons to perform various minor operations upon her body during which she would describe to them and to the assembled students the kind of sensations which she experienced. As she was in the habit of giving these *seances* twice a day for many years at a fee of three and sixpence, she is stated to have amassed quite a small fortune. Such a distinguished voluntary patient as this reminds one of the commoner type of medical examination "subject." Some of these individuals are old hands at the game and know instinctively whether the candidate is on the right track or not. When not absolutely on duty in this strange capacity they wax eloquent upon the nature of their tumour, the types of candidates who have examined them, and discourse in a learned fashion the pathology and prognosis of their affection. Others are just as reticent and afford the anxious candidate no clue whatever, having been fortified, in some

instances, by a crown-piece to "let nothing out to the gentleman." A peculiarly morbid way of earning a livelihood, no doubt, but the hospital "subject" does not regard it in this light. Some people have a natural love of showing their physical abnormalities and imperfections to others, though it is rare to meet with individuals who willingly assist the surgeon in such a manner as Frau Gelly was able to do.

The Church and the Feminine Hat.

HISTORY has repeatedly shown that the religious world is apt to be torn asunder by factions founded on the slenderest issues. There is now some prospect of a war that will split up not only one but all the sects into two sharply divided camps, namely, those who favour and those who condemn the discarding of hats by women attending divine service. It has been suggested that the opposing parties be distinguished as the Hattites and Hussyites, but at this stage of the controversy the step seems somewhat unnecessary and flippant. The origin of the trouble lies in a nutshell. In the search for the simple life the gilded youth of both sexes have hit upon the plan of discarding head-gear indoors and outdoors. In pursuance of that principle a number of women have actually gone to church bare-headed. This act has been denounced by certain clergymen as ribald and blasphemous, and some have gone so far as to exclude hatless women from their churches. It is hard to comprehend on what grounds, religious or otherwise, the objection is based. If men can attend divine service without hats why not women? The Hebrew males keep on their hats in the synagogue as a point of ceremonial, but we know of no doctrine or revelation enjoining rules of any kind regarding hats upon Christian worshippers. From a medical point of view most forms of head-gear are open to serious objection, and wherever possible it would probably be best to do away with hats altogether. Now that the church has turned its attention to feminine millinery it is to be hoped that the matter will not stop at hats. That particular article of millinery is for the most part grotesque, extravagant, and absolutely unfitted for any rational defence against sun, wind, and weather. It is often loaded with the plumage of innocent birds, and, worse than all, has been provided at the cost of sweated workgirls and unpaid milliners. A thousand times better let a woman come hatless to church than worship in a fantastic hat obtained under such unmoral conditions. Let the clergy by all means extend their sumptuary restrictions to the gross extravagance of women's dress and ornaments, but it would be well to hesitate before checking the first voluntary attempt at simpler things. One thing is certain, that if going to church hatless becomes a fashion amongst women all the churches in Christendom will be unable to stop the way.

Overcrowding in Dublin.

THERE is no sanitary question at the present day more pressing than that of the healthy housing of the working classes and of the poor, and in no city of the Kingdom is the problem more important than in Dublin. As is well-known Dublin shows consistently not merely the highest death-rate in the United Kingdom, but one of the highest in Europe, and this death-rate is in the main due to a preponderance of diseases of the respiratory organs, phthisis being excessively common. The evil influences of overcrowding, however, are by no means limited to the spread of such infectious diseases as tubercle, but show themselves in the increased severity of every disease, and in a hundred and one social and moral results which tend to the degradation of the community. Dr. Antony Roche, in a valuable paper contributed to a recent number of the *New Ireland Review*, and reprinted (a), gives interesting figures comparing the condition as regards housing of the poor of Dublin with that of the poor of other cities. It appears that of the 59,263 families in Dublin, 21,747 or 36.7 per cent. live in tenements of one room each. This is the highest percentage in the Kingdom, Glasgow coming next with 26.11, and Belfast showing best among the large cities with only 1 per cent. Dr. Roche discusses at length the merits of the different methods of coping with the housing difficulty, and argues strongly in favour of the single-house plan as opposed to the artisan-block system. There is no doubt that a system of decentralisation such as the single-house plan involves presents many social and sanitary advantages, but the question is one that has to be decided in most cases by local considerations, such as distance and facility of transit. It is not to be forgotten, moreover, that difficult as is the question of housing the artisan, that of housing the very poor is infinitely more so.

Illegal Practice Abroad.

IT may be some consolation, however improper, to the members of our profession in these countries to reflect that they do not suffer alone in being subjected to the annoyance of the competition in practice of large numbers of unqualified persons. In other countries the evil is, if possible, even greater than here, and laws seem powerless to protect the public from the wiles of the mountebank America is, as is well known, the happy hunting-ground of the charlatan, and the lively imagination of the people of that continent seems to render them an easy prey to every kind of impudent imposture. In France, too, practice by unqualified persons has become so great an evil as to demand very sharp legal measures if the safety of the public is to be assured. In particular the number of so-called "masseurs" is in recent

(a) "The Housing of the Working Classes." Dublin: Browne & Nolan. 1905.

years enormously increased, and many of these people hold themselves out to treat all diseases. It is true that unqualified practice is punishable by a fine in France, but the police are usually slow to move in such matters and only prosecute when they cannot avoid it. Even in cases of conviction, the fine imposed is only a matter of five or ten pounds, and this is barely a set-off against the advantages of the advertisement gained by the fact of prosecution. In a recent work on the subject Dr. Lèvre points out that the title "qualified masseur" (*masseur diplomé*) is one which constantly deceives the public, who are unaware that the parchments conferring the title can be bought for so many francs from the enterprising dealer in diplomas, just as at one time a certain pseudo-prince did a large trade in bogus orders of honour.

Bacilluria in Typhoid Fever.

SINCE it was pointed out some years ago that the presence of typhoid bacilli in the urine of typhoid patients is a common occurrence, much attention has been paid to the necessity of taking steps to prevent infection by means of the urine. Formerly it was thought that if the fæces were properly sterilised or destroyed the risk of spreading the infection was minimised if not abolished, and no attention was paid to the urine as a separate factor. With the discovery, however, of the presence of bacilli in the urine, and more particularly with the recognition that bacilli may persist in the urine well on into convalescence, a wider view of the hygiene of typhoid fever is prevalent. It is now generally known by hospital physicians that a typhoid patient should not be discharged until repeated examinations have shown his urine to be sterile. In order to hasten this condition various plans have been devised, and various drugs employed. In cases where there is a distinct cystitis, irrigations of the bladder with mercuric chloride, with potassium permanganate, with boracic acid, with silver nitrate, and other antiseptics, have been made use of with varying success, while for internal use ureteropin has gained a high reputation. There seems little doubt that this drug, although it sometimes gives rise to untoward symptoms, usually has a marked influence in disinfecting the urinary passages. Dr. Easton, of Boston, U.S.A., in a recent paper (a) suggests an extension of its use. He thinks that it should be used not merely in cases where the urinary passages are already infected, but that if systematically employed in typhoid fever, it will have a beneficial effect in preventing the occurrence of bacilluria. Observations made in the Massachusetts General Hospital during last year have shown that with routine employment of the drug, the percentage of patients with typhoid bacilli in the urine was greatly diminished, so that it is probable the treatment will come into more general use.

(a) *Boston Med. and Surj. Journ.*, August 17th, 1905.

PERSONAL.

AMONGST the sufferers from the terrible railway accident last week at Witham we regret to note the name of Dr. Nicholls, of Glencoe, Cromer, who is reported as having sustained an "injury to the back."

THE Francis Galton Scholar in National Eugenics, Mr. Edgar Schuster, will publish a report on his research into the inheritance of disease.

SURGEON LIEUTENANT-COLONEL C. R. KILKELLY, C.M.G., M.B., B.Ch., D.P.H., late Grenadier Guards, has been appointed House Governor and Medical Superintendent of the Convalescent Home for Officers, Osborne, in room of Commander Powell, resigned.

MR. EDGAR HOFFMEISTER, M.B., M.R.C.S., has been appointed a member of the Consulting Staff of the Osborne Home for Officers.

MISS F. SABIN has been appointed Associate Professor of Anatomy in the Johns Hopkins University.

MR. E. G. BAWDEN, of the Stock Exchange, London has given £100,000 to various medical charities and other works of benevolence. The division of this princely gift has been entrusted to Mr. Edgar Speyer. A list of the various charities benefited will be found in another column of the present issue;

THE RIGHT HON. LORD STRATHCONA AND MOUNT ROYAL, G.C.M.G., has been elected President of the Royal Institute of Public Health.

THE Harben lectures at the Royal Institute commence on Oct. 10th. Professor Thomas Oliver, F.R.C.P., of Newcastle-on-Tyne, is this year's lecturer.

Special Correspondence.

[FROM OUR OWN CORRESPONDENT.]

BELFAST.

REPORT ON THE HEALTH OF THE CITY OF BELFAST FOR THE YEAR 1904.—This report, just published, is, as in former years, chiefly remarkable for its brevity and incompleteness, and reflects anything but credit on the city and the Public Health Committee under whose auspices it is published. Belfast is a busy commercial city of about 360,000 inhabitants, with numerous different trades and occupations, yet the whole history of the public health department for a year is compressed into 45 pages, of which one is title, two are blank, and 16 or 18 are absolutely useless padding! The useful part of the report is comprised in 17 tables and some remarks on them. The first table shows the number of infectious cases reported during the years 1895 to 1904. They numbered last year 2,486, being less than any year since the Act came into regular working in the city. There were 1,018 cases of typhoid and simple continued fever, 635 of scarlet fever, 209 diphtheria, 135 small-pox, and 9 typhus. The second table shows the cases notified in the various dispensary districts, but as there is no map of the city, this is quite useless to the ordinary reader, who does not know exactly where the districts are situated. Table 3 shows the births and deaths for each quarter, and the chief causes of the latter. This shows that typhoid caused 111 deaths in the year—19, 20, 30, and 42 in successive quarters; while from diarrhoea the deaths were 251, of which no less than 158 were in the third quarter. The next table gives the numbers of deaths from different zymotic diseases in the past ten years. The most interesting point is that the typhoid deaths are less than any former year in the table.

Pages 9 to 15 of the report are padded with a geographical description of the various dispensary districts, apparently to assist the reader to mark them out

on a map of his own, as no map is given, and no one can carry in his head the various boundaries. The next nine pages are filled with still more useless padding, a description of the weather month by month through the year 1904, and notes on the prevailing diseases. These pages appear every year in the report, and, indeed, constitute its main feature. It is full time they were dropped and some real information substituted for them.

Table 8 shows the annual birth and death-rate in the principal urban districts of Ireland in 1904. It appears that Belfast had a birth-rate of 31.6 per 1,000, only surpassed by Dublin with 32, the lowest being Drogheda with 23.1. The death-rate from zymotic disease was 2.7 in Dublin, 2.5 in Belfast, and only .4 in Dundalk. The next table gives the rainfall month by month for 1903 and 1904 as recorded at the Antrim Road Water Works, but though interesting this is not entirely satisfactory, as this station is close to the hills and much wetter than the south and east sides of the city. The rainfall as recorded at Queen's College ought to have been given. The fall last year amounted to 37 ins., and the year before to 44. Table 10 shows the average annual death-rate per 1,000 from phthisis and other chest affections in various Irish towns. The rates for phthisis vary from 1.3 in Newry to 4.6 in Cork, Belfast having 3.1, and Dublin 2.9, but these variations are small compared to those of the rate for other chest affections, which are indeed so great as to cause one to doubt their accuracy. The rate varies from .7 in Drogheda and .9 in Tralee, to 4.6 in Dublin, 4.9 in Belfast, and 7.4 in Galway. The rate from phthisis in Belfast shows a slow but steady improvement during the last ten years, and the four pages devoted to notes on this disease, and what is being done to combat it, are quite the best part of the report. The medical officers of the dispensary districts now notify phthisis voluntarily, and during the year 1906 cases were notified by nine of the fourteen officers. All the houses where these cases occurred were visited by female sanitary inspectors, who gave instruction to the people on the advantages of fresh air, &c. Several pages are devoted to the study of the recent outbreak of small-pox, but this has already been fully discussed in your columns, so need not be criticized here. The only new feature in the report seems to be an addendum of two pages on the work of the inspector under the Factory and Workshop Act. He paid over 3,000 visits to factories, workshops, and bakehouses, and his visits resulted in the sanitary condition of many of these places being improved. Three charts showing the mortality week by week complete the report.

So much for the contents of the report. The omissions are much more remarkable. We are spending thousands on experiments at the sewage works, trying new schemes for the purification of the sewage and the improvement of the sanitary condition of Belfast Lough, but not a word of these matters is to be found. We have an expensive destructor for dealing with town rubbish, but no mention is made of it, and we are left to meditate on the popular report that it does not work, never has worked, and never will work. Of the ordinary routine work of the officials of the Public Health Department in inspecting drains, cleansing ashpits, &c., and inspecting meat and milk, we are left in blank ignorance. We would suggest that in his next report the Medical Officer of Health should inform us:—

1. In how many houses the drains have been inspected, and in how many found defective.
2. How many samples of food and drink have been analysed, and how many found adulterated.
3. How many carcases have been examined, and how many rejected as unfit for food.
4. What steps are being taken with regard to the flesh of tuberculous animals.
5. Whether any inspection of the great quantities of fruit now brought into the city from abroad takes place, and, if so, what the result has been.
6. How many days the destructor has worked, how many tons of rubbish it has destroyed, and what temperature is maintained in it.

7. What proportion of the sewage of the city is now dealt with by the bacteria beds, and what opinion he has formed as to their efficiency and economy.

8. Whether the united brains of his department would be equal to producing an index to his next report.

Obituary.

KEVIN IZOD O'DOHERTY, M.D.

THE Australian mail brings news of the death at the age of 81, of Dr. Kevin Izod O'Doherty, the last of the Irish State prisoners who were transported to Tasmania for complicity in the insurrection of 1848. He was only a medical student in Dublin at the time, but with a brother-student, Richard Dalbie Williams, he started a revolutionary paper called *The Irish Tribune*, which was soon seized and suppressed by the Castle authorities. After a few years he was pardoned by Queen Victoria, and having taken his degrees in Dublin, he settled in Brisbane, the capital of Queensland. He sat in both Houses of the Queensland Parliament, and was also, on the invitation of Mr. Parnell, M.P. for Meath in the House of Commons for a brief period in the eighties.

DR. ERNST THEODOR SCHWEIGGER.

DR. ERNST THEODOR SCHWEIGGER, the eminent oculist, and Professor of Ophthalmic Diseases at the Berlin University, died last week after a long illness at Berlin.

CYRIL HENRY CAYLEY, M.A., M.B.CANTAB.
M.R.C.S., D.P.H.

WE regret to announce the death of Dr. C. H. Cayley, Divisional Health Officer of the Bombay Municipality, which took place on July 31st, at Bombay. Dr. Cayley had one of his fingers injured some time ago, but it did not give much trouble until tetanus suddenly set in. He was removed to the hospital, where an operation was performed, but all the medical efforts to save his life proved futile. Dr. Cayley was born in September, 1865. His official record shows a brilliant University career and he held the Cambridge M.B., with the English M.R.C.S., and D.P.H. He went out to India about ten years ago on plague duty. He joined the Bombay Municipality as one of its Divisional Health Officers on January 27th, 1900, and held the appointment till the time of his death. Dr. Cayley leaves behind him a widow and small family, who only recently returned to England.

WILLIAM FULLER, M.B.T.C.D., L.R.C.S.I., J.P.,
OF OSWESTRY.

THE death took place on the 29th ult. within a week of the completion of his ninetieth year, of Dr. William Fuller, a well-known practitioner of Oswestry. Dr. Fuller was a Bachelor of Medicine of Trinity College, Dublin, and began practice in Oswestry in 1842, the year in which he graduated. He enjoyed a large practice for forty years and retired in 1882. He was a Churchman and a consistent Liberal; but he took no part in public life. He was a justice of the peace for the borough, and sat regularly until his hearing began to fail.

FARQUHAR MATHESON, M.B., C.M. ABERDEEN.

WE regret to announce the death of Dr. Farquhar Matheson, of London, which occurred at his London residence on the morning of the 23rd ult. Dr. Farquhar Matheson was born of a Highland family in the parish of Kintail, on May 14th, 1840, so that he was in the sixty-sixth year of his age. After studying both at Glasgow and at Aberdeen, he graduated in medicine at the latter University in 1868, and then went to London, where he entered upon a successful professional career, and became recognised as a skilful specialist in diseases of the ear, nose, and throat. He was one of the surgeons of the Royal Ear and Throat Hospital, surgeon to the British and Foreign Musical Society, honorary aural surgeon to the Royal Caledonian Society, honorary surgeon to the Royal Scottish

Hospital, and a Fellow of several learned and scientific societies.

**FREDERICK CHARLES MUDD, M.R.C.S., L.S.A.,
OF CHICHESTER.**

We regret to announce the death of Mr. Frederick Charles Mudd, M.R.C.S., L.S.A., who died at Chichester on the 24th ult. Born at Hadleigh, Suffolk, on January 22nd, 1840, he received his medical education at Guy's Hospital. He started his medical career at Uckfield, and afterwards joined his father, the late Dr. William Mudd, at West Pallant, Chichester, in which practice he continued till his death. For thirty years he held the honorary post of surgeon to St. Mary's Hospital, previously held by his father. He was also for some time assistant surgeon at the Chichester Infirmary, and in his earlier days he will be remembered as Secretary of the Sussex Branch of the British Medical Association. His death will be deeply regretted in the district. He took the M.R.C.S. of England in 1862 and the L.S.A. in 1866.

DR. THOS. HERBERT LITTLEJOHN.

We regret to announce the death of this gentleman, which occurred at his residence at Hampstead on Monday last after a brief illness of only three days. Deceased is the son of Sir Henry Littlejohn, M.D., of Edinburgh, for whom the deepest sympathy of the profession will be evoked. Dr. Herbert Littlejohn was appointed medical officer of health for the borough of Hampstead in 1901, and was only thirty-seven years of age. He was an ardent sanitarian, and much respected in the district.

New Instruments.

**NEW IMPROVED RECTAL SPECULUM WITH
MAGNIFYING LENS ATTACHED.**

Suggested by Sir LAMBERT H. ORMSBY, M.D., F.R.C.S., ex-President of the Royal College of Surgeons in Ireland; Senior Surgeon of the Meath Hospital and Co. Dublin Infirmary.

All who have had much special practice in rectal surgery know how difficult it is in many cases to explore and ascertain accurately the appearances *in situ* of growths, ulceration, &c., and to observe as well the normal and abnormal mucous surface of the rectum some inches from the anal orifice. After careful exploration with the finger, one would always like to have anocular inspection of the cause of pain, such as is produced by ulceration, abnormal growths, piles, or

polypi in this region, and for such a purpose I have had an improved rectal speculum constructed which is easy of introduction with a split, or space, at the side, and open at each end, provided with a wooden plug to facilitate its painless introduction, and having at its lower end a convenient handle to hold it by. Attached to the outer opening of the speculum is a metallic half circular rim for the purpose of receiving a powerful

magnifying glass lens which can be moved in any direction, but can at the same time if necessary be permanently fixed by screwing the handle up tight so as to grip the metallic bar which holds the lens.

This speculum and lens I have been using for the last few months, and it admirably carried out the object in view. It largely magnifies and thus enables the surgeon to see plainly the exact condition of the mucous surface of the lower rectum. I have to thank the eminent firm of instrument makers, Messrs. Mayer and Meltzer, 71, Great Portland Street, London, W., for the satisfactory manner in which they have carried out my idea in its construction.

The plate which illustrates this description accurately depicts the speculum in question. If it is desired to throw light into the speculum when introduced a small electric light can be used with great advantage.

Literature.

**LAKE AND BARWELL ON LARYNGEAL
PHTHISIS. (a)**

MR. LAKE's concise and eminently practical monograph has ably met the want of the busy practitioner for a serviceable handbook on tuberculosis of the larynx. In the present edition Mr. Harold Barwell has exercised the function of editor with judgment and discretion and the book, although retaining its former appearance and justly valued useful characters has been revised, expanded, and thoroughly brought up-to-date. The author and editor wisely include references to cases dealt with in their practice at the Mount Vernon Hospital. The work admirably summarises the chief pathological and clinical features of laryngeal tuberculosis and offers a strong plea for early and active treatment. We regret that the old-fashioned and in many ways unsatisfactory title of the book should have been retained. We note also that "tubercular" is used throughout, whereas most modern writers now employ the more correct expression "tuberculous." Perhaps the most praiseworthy features of the volume, viewed at least from the standpoint of the general practitioner, are the excellent illustrations and the clear indications for treatment. The formulæ given in the appendix might with advantage be considerably extended. We commend this manual to the attention of all practitioners. It should do much to stimulate study of conditions at present sadly neglected.

MANUAL FOR CORONERS. (b)

THIS work is a guide to coroners' inquiries in South Australia, Australasia, and England. With index it numbers 153 pages, and is divided into eight parts, each of which is sub-divided into chapters.

Actual procedure—the same in the main in Australia as in England—is set forth step by step in a more practical and simple fashion than in any other work known to us. The first portion of each chapter in Parts I. to V. refers to coroners' law and procedure in South Australia (within the author's jurisdiction). The latter portion deals with the differences that exist in England and the various districts of Australasia, namely, in New South Wales, Queensland, Tasmania, Victoria, Western Australia, and New Zealand. Coroners, deputy coroners, and acting coroners are in Australasia, we are told (in Part I.), appointed and removable by the Governor-in-Council or by the Crown and are *ex officio* justices of peace. Any justice of the peace may—unlike English law—act as coroner with all the powers and authorities of such. He acts without fee, his expenses only being paid. Coroners in Australasia inquire into the cause and

(a) "Laryngeal Phthisis or Tubercular Laryngitis." By Richard Lake, F.R.C.S. Second Edition, Enlarged and Re-written by Harold Barwell, M.B.Lond., F.R.C.S.Eng., Laryngologist, Mount Vernon Hospital. Pp. 120, with 45 illustrations, 20 of which are coloured. London: Bailliere, Tindall and Cox. 1905. Price 6s. 6d.

(b) "A Manual for Coroners." By M. Ramsay Smith, M.B., B.Sc. (Edin.), City Coroner for Adelaide. London: Hussey and Gillingham. 1904. 10s. 6d.

origin of fires—"whether a bush or other fire, whereby any building, ship, merchandise, or any stack of corn or hay, or any growing crop, pasture, or any other valuable effects shall be endangered, destroyed, or damaged." One of the most interesting sections is under Part V., on "Inquests in cases of Fire." In South Australia the coroner holds inquests in cases where there is evidence of arson or "of such carelessness as might give rise to suspicion against some one." In England, the author observes, the only one who has power to inquire into the cause and origin of fires is the City coroner within the City of London "acting for the Sheriff." The latter part of this statement is incorrect, the Sheriffs never having had any jurisdiction over fires. In Victoria a coroner cannot inquire into the cause of a fire until some person has paid five guineas to the Coroner with a request that he should hold an inquest.

In England if twelve of the jury do not agree as to their verdict the Coroner adjourns the inquest to the next criminal sessions. In Victoria if a majority of the jurors do not agree after two hours, the coroner may discharge them and hold a new inquest with an entirely new jury. The author very justly points out how illogical is the stereotyped verdict that deceased took his own life in a fit of temporary insanity, since the duration of the insanity is a subject on which the jury could not possibly have any real knowledge. The verdict in such cases should be merely whilst of unsound mind.

Literary Notes and Gossip.

The *Braille Weekly* forms one of the most remarkable of modern journalistic ventures. It is published in the well-known raised type for the use of the blind invented by Dr. Braille. A number of subjects are dealt with in its columns, or rather pages, including parliamentary and general news, special articles, chess problems and so on. We regret to note that the journal is not a financial success, and that appeals are being made for charitable support. It would be difficult to imagine any enterprise more worthy of support. Donations can be sent to the Editor, Braille Company, 24, St. Giles's Street, Edinburgh.

The *Edinburgh Medical Journal* (New Series, Vol. XVII.) possesses a special interest in containing a series of portraits of some of those men who have helped to build up the fame of the Edinburgh School. These have been introduced as a fitting accompaniment to the centenary number of the journal, which forms the opening number of the present volume. In our review of the last volume we referred to the fact that just a century had passed since the first appearance of the journal in its embryo form, and this is now fittingly marked by a retrospect of the medical sciences extending over the lifetime of the publication. To all Edinburgh students this number must be welcome, showing as it does the part that their predecessors and contemporaries have played in establishing the fame of their school, and in adding to the fabric of medical knowledge. In the remainder of the volume one or two papers are of importance. That by Boyd and Beattie on "Decapsulation of the Kidneys," gives a good account of the changes found *post-mortem* in a kidney which had been decapsulated four months previously. As in other reports of similar cases, there was present marked adhesion between the kidney and surrounding structures; the capsule (apparently a new formation) was thick, stripped with difficulty, and in stripping caused considerable laceration. Within the capsule many large vessels were found, which, however, the writers think could hardly more than compensate for the normal communication between renal and peri-renal vessels necessarily destroyed by the operation. Another interesting paper is that on "Late Rickets," by W. Marsden, while that on "Poisoning in Scotland," by Francis Stewart, forms most entertaining reading.

"Anæsthetic Difficulties and How to Combat Them" is the title of a brochure by Mr. de Prenderville, anæsthetist to the Tottenham Hospital. It is a reprint of an article that appeared some little time ago in the *MEDICAL PRESS AND CIRCULAR*, and those of our readers who did not read it at the time will find it well worthy of their attention. It is brightly written, practical, and suggestive. Price 1s. nett.

Messrs. Longmans, Green and Co. have issued in book-form the Report of the Committee of the Medico-Chirurgical Society which lately held an inquiry into the Phenomena attending Death by Drowning and the Means for Promoting Resuscitation in the Apparently Drowned.

Mr. Theodore Dodd, a prominent character in the public life of Oxford, has written an open letter to the President of the Local Government Board, which deserves careful consideration not only by that Minister but by all who are concerned for the health of the nation. Mr. Dodd has secured a preface from the pen of Sir John Gorst, a circumstance which is in itself sufficient to command respect for its contents; for Sir John Gorst, however embarrassing he may be to his political friends, is recognised by the medical profession generally as a publicist of rare ability and disinterestedness. Mr. Dodd's object in his letter is a laudable one, namely, to show how much can be done for the physical infirmities of the nation by intelligent and sympathetic administration of the already-existing laws and governmental machinery.

£100,000 Gift to London.

MR. E. G. BAWDEN, of the Stock Exchange and Clapton, has entrusted Mr. E. Speyer with a sum of cash and securities of about £100,000 to be applied to purposes of charity and benevolence and for the advancement of knowledge, especially in aid of human suffering. The gift to the Medical Charities is thus apportioned: *Hospitals*:—King Edward's Hospital Fund, £5,000; London Hospital, £5,000; City of London Hospital, Victoria-park, £3,000; Poplar Hospital, £3,000; National Hospital for the Paralysed, £3,000; Royal Waterloo Hospital, £2,500; Cancer Hospital, £2,500; German Hospital, £2,500; Queen Charlotte's Lying-in Hospital, £2,000; Clapham Maternity, £1,000; Royal Hospital for Incurables, £2,000. *Holiday Funds*:—Children's Holiday Fund, £10,000; Women's Holiday Fund, £2,000; Factory Girls' Holiday Fund, £2,000.

Convalescent and other Homes.—Metropolitan Convalescent Institution, £2,000; Mrs. Gladstone's Convalescent Home, £2,000; East Anglian Sanatorium, £1,000; Kelling Open-Air Sanatorium, £1,000; Mary Wardell's Scarlet Fever Home, £1,000; Homes for Aged Poor, Anerley, £1,000; St. Mary's Home, £2,000.

Institutions for Homeless and Crippled Children.—Dr. Barnardo's Homes, £2,000; National Refuges for Destitute Children, £2,500; Invalid Children's Association, £2,000; Haven for Homeless Little Ones, £2,000; Cripples Home for Girls, £1,000; National Home for Crippled Boys, £1,000.

Compulsory Notification of Measles.

The Plymouth Sanitary Committee last week resolved to recommend the extension for another twelve months of the compulsory notification of measles and whooping-cough, and the voluntary notification of pulmonary tuberculosis. In October the five years for which the Council experimentally adopted those measures will expire, and unless revoked before that time they will continue in operation. The Medical Officer of Health, Dr. Williams, has shown the startling fact that since notification has been in operation the death-rate from the two diseases named has been reduced from '6 to '3 per 1,000 per annum, a reduction of 50 per cent. This means that the adoption of notification has resulted in the saving of 110 lives which would have otherwise been sacrificed to measles or whooping-cough since 1900.

Notices to Correspondents, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

DENTAL (Isle of Man).—Dr. Miller of Berlin declares that antiseptics in dentifrices are wrong in principle as they are likely to destroy protective bacteria normally present in the mouth. The incidence of ordinary dental caries is not obviated altogether by vegetarianism, though there is some evidence to show that it may be thereby lessened.

M. O. H. (Doncaster).—There are only, as far as we can ascertain, about 80 authorised crèches in England. The question is under consideration by the L.C.C., for London at least.

DR. H. M.—The commonest accident among the Chinese miners in S. Africa is that of becoming "gassed" as, in spite of strict orders, they return before the effects of the blasting are quite over. The symptoms are sweating, drowsiness and severe headache which lasts for one or two days, and deaths are said to occur because they do not go into the hospital for treatment at once.

THE TREATMENT OF GONORRHOEA.

Referring to the paper by Mr. H. de Meric, which appeared in our issue for August 23rd, a Paris correspondent writes asking the dosage of argyrol. Having referred the question to the author of the paper, he replies that a 5 per cent. solution would be 5 grammes to 100 grammes of water or other vehicle.

DR. A. D.—The newspapers in the dead season, when there are no parliamentary proceedings and few law cases to report, are driven to appropriate other material to fill their columns. The cutting you enclose is an unfortunate example, but we have ascertained that the particulars were not supplied by the surgeon in charge of the case—with whom we commiserate—but by an official who should have been aware of the impropriety of such conduct.

A SIDE ISSUE OF THE DIMINISHING BIRTH-RATE QUESTION.

The question as to whether families with children should be accepted as tenants in flats is a pressing one, not in this country only, but in America. A recent issue of *Public Opinion* informs us that Cleveland has approached a step nearer the solution of the problem by forming a tenants' protective association. The citizens have grown weary of hearing the landlords dictate to them how and where they are to live, and how many if any children they are to be allowed, and have now come to the decision that any landlord refusing to accept as tenants a family which includes "children" shall be rigorously boycotted until he ceases to act the part of a tyrant, furthering the cause of race suicide.

HOSPITAL.—The Public Hospitals of New Zealand are State Institutions supported by compulsory rating, contributions and patients' fees. The medical men out there are agitating to be represented on the Board of Management.

DR. F. (Amersham).—Bromide of strontium is supposed to produce less acne, but seems to have no superiority over other drugs in arresting attacks of epilepsy. Hydrobromic acid cannot be given in sufficient quantity to be any service.

ERRATA.—In Dr. Wybrants Olphert's letter on "An Anti-vaccination Argument" which appeared in our last issue, the words "the Land of Services" should read "the Land of Jenner."

In our review of Dr. Gould's Dictionary of Medical Terms which appears in the same issue, the word "monolodiddibismuthmethylenedicrosinate," which our reviewer quoted from the work, should read "monolodiddibismuthmethylenedicrosinate." A printer's error in such a case is however excusable.

DR. D. MACKAY.—Your paper on "The Functional Examination of the Ear by Means of the Voice" is marked for early insertion.

Vacancies.

- Lister Institute of Preventive Medicine.—Assistant Bacteriologist. Salary £150 per annum. Applications to the Secretary, Lister Institute, Chelsea Garden, London, S.W.
- Hospital for Sick Children, Newcastle-on-Tyne.—Male Resident Medical Officer. Salary £100 per annum, with board, lodging and laundry. Applications to Alf. E. Birch, Secretary, Secretary's Office, Hospital for Sick Children, City Road, Newcastle-on-Tyne.
- County Borough of Tynemouth.—Medical Officer of Health. Salary £300 per annum. Applications to E. B. Sharpley, Town Clerk, Town Hall, Tynemouth.
- Metropolitan Water Board.—
A Senior Chemical Assistant. Salary £300 per annum.
A Senior Bacteriological Assistant. Salary £300 per annum.
A Junior Chemical Assistant. Salary £175 per annum.
A Junior Bacteriological Assistant. Salary £175 per annum.
Two Laboratory Assistants. Salary '75 each, per annum.
Applications to A. B. Pilling, Clerk of the Board, Savoy Court, Strand, W.C.
- The University of Melbourne.—Professor of Anatomy. Salary £900 per annum. Applications to the Agent-General for Victoria, 142 Queen Victoria Street, London, E.C.

Medical Officer wanted for a Mining Co. in Spain.—Salary £400 per annum, with house, attendance, fuel, lights, &c. Applications to Mr. Percival Turner, 4 Adam Street, Adelphi, London, W.C.

The Guest Hospital, Dudley.—Senior Resident Medical Officer. Salary £100 per annum, with board, residence, attendance, and washing. Applications to the Secretary.

Waterford County and City Infirmary.—Superintendent of Nurses. Salary £80 per annum, with board, &c. Applications to Secretary. (See Advt.)

Appointments.

ELLIS, F. H., B.A., M.B., B.C. Cantab., M.R.C.S., L.R.C.P., Assistant Resident Medical Officer at the London Open-air Sanatorium, Pinewood, Wokingham, Berks.

GLAISER, HOWARD, M.B., B.C. Lond., M.R.C.S. Eng., L.R.C.P. Lond., District Medical Officer, to the Mildenhall Union.

PANK, HAROLD W., M.R.C.S. Eng., L.R.C.P. Lond., District Medical Officer to the Calster Union.

ROUTLEY, EDWIN WALTER, M.D. Brux., M.R.C.S. Eng., L.R.C.P. Lond., Medical Officer of Health for Aldershot.

THOMPSON, ALEXANDER DEY, M.B., Ch.B. Glasg., Senior Assistant Medical Officer to the Monmouthshire Asylum, Abergavenny.

Births.

EVERY-CLAYTON.—On August 30th, at Rosslyn, Clevedon, Somerset, the wife of L. Ernest Every-Clayton, M.D., F.R.C.S., of a daughter.

TWEEDY.—On August 1st, at Abbey House, Kenilworth, the wife of Reginald Carlyon Tweedy, M.R.C.S., L.R.C.P., of a daughter.

Marriage.

HAY-GROVES.—On August 30th, at Holy Trinity Church, Weymouth, Archibald Gilchrist Hay, M.A. M.D., son of Alexander Hay, M.D., of Maryhill, Glasgow, to Mabel Constance, youngest daughter of Sir John Groves, of Rodwell, Weymouth.

Deaths.

LITTLEJOHN.—On September 4th, at 37 Buckland Crescent, Hampstead, after a short illness, Thomas Herbert Littlejohn, F.R.C.S., Ed., son of Sir Henry Littlejohn, Edinburgh.

MCDONAGHY.—On September 3rd, at 5 Granville Place, Portman Square, London, Surgeon-General William McDonaghy, M.D., Indian Medical Service.

OPERATIONS—METROPOLITAN HOSPITALS.

WEDNESDAY.—St. Bartholomew's (1.30 p.m.), University College (2 p.m.), Royal Free (2 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. Thomas's (2 p.m.), London (2 p.m.), King's College (2 p.m.), St. George's (Ophthalmic, 1 p.m.), St. Mary's (2 p.m.), National Orthopaedic (10 a.m.), St. Peter's (2 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Gt. Ormond Street, (9.30 a.m.), Gt. Northern Central (2.30 p.m.), Westminster (2 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), Cancer (2 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).

THURSDAY.—St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), University College (2 p.m.), Charing Cross (3 p.m.), St. George's (1 p.m.), London (2 p.m.), King's College (2 p.m.), Middlesex (1.30 p.m.), St. Mary's (2.30 p.m.), Soho Square (2 p.m.), North-West London (2 p.m.), Chelsea (2 p.m.), Great Northern Central (Gynaecological, 2.30 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), St. Mark's (2 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).

FRIDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), Guy's (1.30 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. George's (1 p.m.), King's College (2 p.m.), St. Mary's (2 p.m.), Ophthalmic (10 a.m.), Cancer (2 p.m.), Chelsea (2 p.m.), Great Northern Central (2.30 p.m.), West London (2.30 p.m.), London Throat (9.30 a.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), City Orthopaedic (2.30 p.m.), Soho Square (2 p.m.).

SATURDAY.—Royal Free (9 a.m.), London (2 p.m.), Middlesex (1.30 p.m.), St. Thomas's (2 p.m.), University College (9.15 a.m.), Charing Cross (2 p.m.), St. George's (1 p.m.), St. Mary's (1 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).

MONDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), St. George's (2 p.m.), St. Mary's (2.35 p.m.), Middlesex (1.30 p.m.), Westminster (2 p.m.), Chelsea (2 p.m.), Samaritan (Gynaecological, by Physicians, 2 p.m.), Soho Square (2 p.m.), Royal Orthopaedic (2 p.m.), City Orthopaedic (4 p.m.), Great Northern Central (2.30 p.m.), West London (2.30 p.m.), London Throat (9.30 a.m.), Royal Free (2 p.m.), Guy's (1.30 p.m.).

TUESDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), Guy's (1.30 p.m.), Middlesex (1.30 p.m.), Westminster (2 p.m.), West London (2.30 p.m.), University College (2 p.m.), St. George's (1 p.m.), St. Mary's (1 p.m.), St. Mark's (2.30 p.m.), Cancer (2 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), Royal Free (3 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), Soho Square (2 p.m.).

The Medical Press and Circular.

“SALUS POPULI SUPREMA LEX.”

VOL. CXXXI. WEDNESDAY, SEPTEMBER 13, 1905. No. II.

EDUCATIONAL NUMBER, 1905—1906.

INTRODUCTORY REMARKS.

THE choice of a future calling is naturally one of the turning points in a man's life. Yet it is sometimes decided, as it were, by a mere straw of chance, and the young man drifts into a position that should be chosen only after a careful consideration of peculiar aptitudes and advantages of environment. Nowadays the medical profession has no welcome for the idle or the incompetent, who, indeed, have hardly the remotest chance of passing the test of qualifying examinations. Among learned professions, those of law and divinity can hardly be called progressive, whereas progress is inherent to engineering and certain other branches of intellectual activity; but of modern medicine it may be said that progress, unceasing, rapid and all-conquering, is above all things the great essential feature. Brilliancy of mind may still be essential to attainment of the front rank in the medical world, but none the less for the average practitioner sustained energy and devotion to his chosen life work will prove far more valuable ballast. Let parents, therefore, consider the solid and less showy virtues in determining the fitness or otherwise of a son, or of a daughter—for both sexes must now be included—for the practice of this most honourable but exacting profession.

As regards the material rewards of the profession, the aspirant should recognise from the outset that the labourers are many in proportion to the harvest. Any man who wishes to amass a fortune before middle age had better make up his mind to follow some business occupation. As a medical practitioner he will, as a rule, make enough to live upon within a short time of starting practice. Where there is much competition, however, he will find it hard to get beyond that amount, and as a rule his increased income is swallowed up by greater expenses. A large practice, whether general, special, or consultant, can be built up only by years of hard and conscientious work, at the end of which a moderate fortune will probably have been amassed. In all cases, the young medical man will find it desirable to be provided with a sufficient sum of money either to buy a practice or to furnish a house and tide over the first years of waiting. Should he wish to enter the Public Health Service he will have to devote several years to acquiring a special knowledge of the duties to be performed in the office of a medical officer of health. Or he may prefer to enter the Army, Navy, or Indian Medical Services, which carry pay

from the time of appointment and confer a pension upon retirement; latterly something has been done to render these Services more popular, but much remains to be done in that direction. Then there are lunacy, Poor-law, and Local Government Board appointments, some of them well-paid and highly responsible posts. Lastly, the medical student may have made up his mind to tread the honourable but thorny paths of the consulting surgeon or physician, or of the specialist. In that case he must be provided with means to support him through ten years or more that will be required to enable him to earn a livelihood. Many men whose names have become household words have had to endure year after year of penury and self-denial. Indeed, no profession, not even excepting that of the barrister, could furnish more instances of hard living and high thinking than that met with in the ranks of consultant surgeons and physicians. On the other hand, the prizes to be gained in the higher branches of the profession are considerable, when tested by such acquisitions as social position, titles, honours, influence and substantial income. At the same time, it must be borne in mind that not a few men of unblemished reputation and of great intellectual and professional acquirements live and die without having gained the favours of fortune. To succeed in these directions requires the possession of moderate means, average intellectual endowments, good education, a hospital appointment, a good address, and an iron resolution. Success, moreover, requires a certain business-like attitude towards the affairs of life, the lack of which quality has blighted the career of many a good scientist and worthy citizen.

One of the fascinations of medicine is its variety, which in its endless wealth of detail compares with the "numberless laughter-dumplings" of the sea spoken of by the old Greek dramatist. To the larger mind which is capable of observing accurately and of generalising from ascertained facts, medicine is indeed a rich mine of Golconda. There is about it the fascination and joy of a daily encounter with a thousand difficulties and obscurities, any one of which may afford the clue to some discovery pregnant of relief to humanity for the rest of the ages. So far as evolution has advanced in medicine, it remains in many directions an inexact science. In other words, there still remains a wide margin of diseased conditions which the medical man is called upon to treat, but for which he can demonstrate no exact principles.

The individual judgment of the medical attendant is, therefore, still an all-powerful element in practice. Until medicine is reduced to an exact science such as mathematics this margin of inexactitude must persist, and give rise to the necessity of much rule-of-thumb practice. The more that is learnt, however, the less room is there for empirical procedure. The surgeon of to-day is fast reaching a stage of all-round exactitude, so far as it can ever be attained in dealing with so complex a thing as the human organism. It should be the aim of every medical student from the day he crosses the threshold of his profession always to seek for the principles that lie at the bottom of all that is practical in his profession. If he acquire this habit it will guide him through the thicket to many avenues of knowledge that would otherwise be impenetrable. For he must not forget that the greater part of his professional life will be passed away from teachers and hospitals in places where he will have to observe and act for himself. Some epoch-marking discoveries have come from the ranks of the general practitioner, and assuredly it is never the material that is wanting.

THE CHOICE OF A SCHOOL.

The choice of a medical school often hinges upon the accidents of time, place, or tradition. Many students nowadays go to one of the excellent provincial schools in their neighbourhood. Many others, again, are attracted to the Universities, North or South of the Tweed, or across the Irish Channel, which grant the degree of M.D. without exacting an abnormally high standard of examination. Men who are receiving their general education at one of the Universities will naturally enter the medical school attached to their Alma Mater, at any rate for a portion of the five years' medical curriculum. In some few instances the possession of a University qualification is made a *sine qua non* in the holding of some coveted hospital or other professional appointment. There may be some sort of excuse for this species of organised "protection," which the labouring classes would call "trades-unionism," in the case of the professorships and examinerships in some of the ancient Universities. When a similar exclusion, however, is applied by medical charities the situation becomes intolerable. The fact remains, however, that in the majority of English hospitals and infirmaries none but London graduates and diplomates need apply. A newly formed association of Scotch Diplomates—many of whom are Englishmen and Irishmen—are calling attention to the unfairness of the conditions that exclude them from holding honorary appointments on the medical staffs of many English charities. These facts may possibly furnish useful hints to the intending student, who has to make the best of present conditions.

THE CHOICE OF QUALIFICATIONS.

The student is early called upon to define his aims; in other words he has to decide through what portal he will enter the profession. The point is one of unquestionable importance, because there is no going back on the choice later in the student-career. The reorganisation of the University of London has rendered it possible for the average student to obtain a degree in medicine on terms less prohibitive than was formerly the case, but the fact remains that although the purely medical standard is attainable by any fairly diligent student, the matriculation examination and that in science nevertheless constitute serious stumbling blocks. The average student will probably find it more convenient to take the diplomas of the English Conjoint

Board, and, should he deem a degree worth the extra trouble, he can put in attendance at one or other of the provincial Universities with the view of subsequently passing the examinations for the doctorate. Or he may choose to take a qualification or degree in the Scotch or the Irish schools, where education is sound, practical, and well-equipped, and the traditions of the teachers are unrivalled.

THE COURSE OF STUDY.

It is unnecessary to discuss the details of the medical curriculum. We would, however, impress upon the student the importance of entering upon his work earnestly, with firm determination to familiarise himself with the subjects—*anatomy, physiology, and materia medica*—which constitute the threefold basis of practical medicine. With regard to *anatomy*, the only valuable knowledge is that gained by actual dissection of the dead body. Verbal descriptions and plates are only aids to knowledge, not knowledge itself. Dissection gives information at first hand—actual knowledge, not mere statements—and the practice of dissection is, in fact, a first course in surgery. We would warn the student against that form of intellectual laziness which consists in abandoning the dissecting room in favour of the library. At the same time, an exception must be made so far as an excellent stereoscopic atlas of *anatomy* is concerned; it affords a capital means of refreshing the memory of details of past work done in the dissecting room. The midnight oil may enable the student to pass examinations, but it will never confer that intimate familiarity with the things themselves, which is indispensable to success in practice. Nor should he despise that somewhat arid subject, *materia medica*. A knowledge of the physical properties of drugs and of their physiological action is all-important to the hospital physician as to the general practitioner. Treatment is the ultimate object of all medicine, and the medicinal treatment of disease is still an integral part of the practice of medicine.

THE CLINICAL WORK.

It is in the wards and in the out-patient department, after all, that the student acquires most of his information concerning the course and treatment of disease. There he watches the daily progress of morbid processes, and learns the means employed to afford relief or to bring about recovery. It will be his privilege to unravel the tangled threads of each patient's life-history, and by the careful examination of data to arrive at a reasoned conclusion known as the diagnosis. In this way he will gradually learn to recognise the main principles which underlie the practice of medicine. Each patient who comes under his observation will, if properly studied, yield his quota of practical knowledge, and the value of the opportunity depends upon the ability and willingness of the student to avail himself thereof. The object and aim of clinical training is to cultivate the student's powers of direct observation and to train him to make correct deductions, and the habit of careful observation is one which should become second nature. The instruction received in the wards is incomplete unless supplemented by the lessons to be learned in the post-mortem room. There the student can follow the morbid process to its conclusion. The post-mortem room is the natural complement of the ward, and it is often only in this room that the clinical problem is unravelled, and the student enabled to observe the organic lesions which determined the symptoms he has been studying. Incidentally

the student should learn as much as he can of the method of carrying out these examinations, for it falls to the lot of most practitioners to have to make such examinations, and errors of observation or appreciation may be fraught with the gravest consequences to possibly innocent persons.

THE HIGHER QUALIFICATIONS.

There remains the question of the higher qualifications, e.g., the Fellowships of the Royal Colleges, which are indispensable to those who contemplate a hospital career, either as physician or surgeon. The Fellowship of the London Royal College of Physicians is not obtained by examination, but by selection from among the members, but it is nevertheless demanded as a necessary qualification in the holding of many hospital appointments. Candidates for the membership are required to pass a searching examination and to satisfy certain other requirements before they can be admitted thereto, and subsequent elevation to the Fellowship is largely a matter of personal influence, though merit *per se* is not a bar to selection. The Fellowship of the Royal College of Surgeons, on the other hand, is a purely professional distinction, and is open to anyone who can pass the examinations. It is advisable to pass the first examination for the Fellowship as soon as possible after passing the first membership, in order not to have to go over the ground later a second time. The Fellowships of the Scotch and Irish Colleges of Surgeons are conferred after examination, but are not recognised as qualifying for staff appointments by the majority of large English medical charities.

CHOICE OF A CAREER.

When the student has entered the portals of the profession he is confronted with the question of deciding in what particular path he shall direct his energies. Many neo-practitioners, not unwisely, spend a year or two in resident appointments at their own hospitals or at some provincial hospital or infirmary. Others, again, either join their parents in practice or purchase partnerships. Then, too, there are the Services—Indian, Army, Navy, and Colonial—to choose from. The Poor-law Infirmaries provide each year a certain number of appointments, and these are the first rungs of the ladder which leads to the superintendency of these institutions. These posts are fairly remunerated, and afford reasonable security of tenure, but they entail much hard work, together with heavy responsibilities.

PUBLIC HEALTH SERVICE.

Every student who can afford the time is strongly advised to qualify in State Medicine, since this diploma renders its holder eligible for appointment as medical officer of health, and, moreover, the knowledge thus gained is valuable in every department of practice. A diploma in State medicine entails a special course of preparation and training subsequent to qualification, the conditions of which will be found under the appropriate heading. Although the tenure of office is not as yet on a satisfactory basis, there are many appointments of the kind which afford a free field for intelligent activity.

POST-GRADUATE INSTRUCTION.

Medicine has of late years become a field of vastly wider extent and when he enters upon his professional work the conscientious practitioner is apt to experience a painful sense of his shortcomings in many branches of medical practice. The knowledge which has been rendered available of recent years has obviously

placed a peculiar responsibility upon the physician fresh from his studies. The desire so generally felt by men in practice to extend and complete their knowledge of special subjects has led to the organisation of post-graduate institutions on a large scale, of which advantage is freely taken by those who are fortunate enough to reside within accessible distance thereof. We would strongly urge senior students and young practitioners to avail themselves of every opportunity to acquire a working knowledge of the various special branches—eye, ear, throat, gynaecology, and so on. This leads us to the question of

SPECIALISM IN MEDICINE.

Hitherto the student has been taught that "the greatest mistake of all is to start in a specialty without being thoroughly grounded in general practice." The statement is undoubtedly true to the extent that it behoves everyone, no matter what particular department of practice he may decide to adopt, to acquire a thorough grounding in the general principles and practice of medicine. On the other hand, there is much to be said in favour of the view that it is best for the young practitioner to make his choice at the earliest possible moment of the line of work which he designs to follow. As soon as he has qualified, therefore, or as soon after as may be, the intending specialist should endeavour to obtain a junior post in one or other of the special hospitals, where he can gradually work his way up.

MEDICAL PRACTICE IN FOREIGN COUNTRIES.

Practitioners qualified in Great Britain who desire to practise their profession abroad are still confronted with many difficulties. True, a step in the direction of reciprocity has been taken in the case of Italy, but elsewhere in Europe considerable difficulty will be experienced in obtaining permission to practise; indeed, it is usually necessary to go through the whole curriculum and pass the examinations in their entirety.

THE ENGLISH UNIVERSITIES.

The English Universities are eight in number, *viz.*, Oxford, Cambridge, London, the Victoria, Durham, Liverpool, Leeds, and Birmingham. The choice of a University is usually determined by social, geographical, and financial considerations. Evidently students whose parents are able and willing to incur the necessary expense would do well to select one or other of the ancient Universities, since their degrees confer upon their holders a status not accorded by the public to the degrees of more modern educational institutions. To those less favoured by fortune, but blessed with energy and a fair share of intelligence, the London University offers ample scope, and its degrees are recognised as the outward and visible sign of high professional attainments. A capable and industrious student, however, may equally well lay the foundations of success in one of the newer provincial universities.

OXFORD.

There are two degrees in medicine, B.M. and D.M., and two degrees in surgery, B.Ch. and M.Ch. The B.M. and B.Ch. degrees are granted to those members of the University who have passed the second (B.M.) examination. Graduates in Arts, B.A., are alone eligible for these degrees. In order to obtain the degrees of B.M. and B.Ch., the following examinations must be passed:—1. Preliminary: Subjects:—Physics, chemistry, zoology, and botany. 2. Professional (a) First examination (held twice a year): Subjects:—Organic chemistry, unless the candidate has obtained a first or second class in chemistry in the Natural Science School; Human physiology, unless he

has obtained a first or second class in animal physiology in the Natural Science School; Human anatomy; *Materia medica* with pharmacy. (b) Second examination: Subjects:—Medicine, surgery, midwifery, pathology, forensic medicine with hygiene. The approximate dates of the examinations are as follows:—Preliminaries:—Physics, and chemistry, December and June; Zoology and botany, December and March; Professional (First and Second B.M.), June and December.

The degree of D.M. is granted to Bachelors of Medicine of the University who have entered on their thirty-ninth term on their presenting a dissertation approved of by the appointed professors and examiners.

The degree of M.Ch. is granted to Bachelors of Surgery of the University who have entered their twenty-seventh term, who are members of the surgical staff of a recognised hospital, or have acted as dresser or house surgeon in such a hospital for six months, and who have passed an examination in surgery, surgical anatomy, and surgical operations. This examination is held annually, in June.

The First examination for the degrees of B.M. and B.Ch. may be passed as soon as the Preliminary Scientific examinations have been completed. The subjects of this examination may be presented separately or in any combination or in any order, provided anatomy and physiology be offered and passed together.

In the Second Examination candidates are allowed to present themselves in Pathology, and also in Forensic Medicine at separate Examinations at any time after the First Examination has been passed; but no candidate is permitted to enter for the Examinations in medicine, surgery, and midwifery until he has attained the twenty-fourth term from his matriculation—i.e., six years.

Diploma in Public Health.—An examination is held yearly in Michaelmas Term. The first part comprises the application of chemistry and physics to general hygiene. The second part comprises the following subjects:—General pathology, with special relation to infectious diseases; the laws relating to public health; sanitary engineering; vital statistics. Both parts may be taken together at the same Examination, or they may be taken at separate Examinations; but no one is deemed to have satisfied the Examiners in Part II. unless he has satisfied the Examiners in the subjects of Part I. A diploma is issued to every candidate who has passed in both parts of the Examination, but no Diploma or Certificate is given under any other circumstances. Candidates must have their names on the "Medical Register" and must have satisfied all the Rules of the General Medical Council of the United Kingdom relating to the admission of Candidates for Diplomas in Public Health which are in force at the time.

More detailed information may be obtained from the "Examination Statutes" with the "Regulations" for the current year, published annually in June at the Clarendon Press Depot, price 1s.

CAMBRIDGE.

At the University of Cambridge five years of medical study are required for the M.B. and B.C. degrees. The candidate must have resided nine terms (three years) in the University, and have passed the "previous" examination in classics and mathematics. There are three examinations: The first in (1) chemistry and physics, and (2) biology; the second in human anatomy and physiology; and the third in (1) pharmacology and general pathology, (2) in surgery, midwifery, and medicine. The first and the third examinations are divided into two parts, which can be taken separately. Subsequently to the third examination an Act has to be kept which consists in reading an original thesis, followed by an oral examination on the subject of the thesis. As the subjects for the examination for the degree in surgery are included in the third examination for the M.B. degree, candidates are admitted to the degree of Bachelor of Surgery on passing the third examination for Bachelor of Medicine.

The M.D. degree may be taken three years after the

M.B. An Act has to be kept, including the presentation of an original thesis, with oral examinations and an essay to be written extempore. There is also the degree of Master of Surgery, for which the candidate, having already passed for B.C., or being M.A., has otherwise qualified in surgery, has to pursue extra study in surgery, and has a special examination or submits original contributions of merit to the science or art of surgery. The yearly expenditure of a student who keeps his term by a residence in a college is from £150 to £200 a year. This, however, may include all payments to the University and the College—all fees as well as clothes, pocket money, travelling expenses, &c. Non-collegiate students have only to pay the University fees, which are not large. They lodge and board as they like; their expenses, therefore, are entirely in their own hands.

The University grants a diploma in public health without the necessity of residence, the examination being in so much of State Medicine as is comprised in the functions of officers of health, and subject to the latest requirements of the General Medical Council. These examinations are held in Cambridge the first week in April and October. Candidates, whose names must be on the "Medical Register" of the United Kingdom, and need not be members of the University, should send in their applications to the Secretary of the State Medicine Syndicate a fortnight in advance. Every candidate who has passed both parts of the examination to the satisfaction of the examiners will receive a testimonial testifying to his competent knowledge of the subjects comprised in the duties of a medical officer of health.

There is also a special examination in Tropical Medicine and Hygiene, held annually in August. It is open to qualified practitioners under certain conditions as to previous study and experience. Successful candidates receive a University Diploma.

An abstract of all Regulations may be obtained upon sending a stamped directed envelope to the Assistant Registrar, Cambridge. Full information is contained in the University Calendar.

UNIVERSITY OF LONDON.

The Medical Faculty grants the degrees of Bachelor of Medicine and Surgery, Doctor of Medicine and Master in Surgery. Under the new regulations the students are divided into "Internal" and "External." An internal student is one who has matriculated at the University and is studying in a school approved by that body, or under the teachers of the University. An external student is one who has adopted an alternative course of study. The regulations differ somewhat in their application to the two groups of students. We only propose to deal with them as they affect *internal* students, since the special information required by the others had best be obtained direct from the Registrar. Under no circumstances will a student be admitted to the final examination for a degree until at least three years have elapsed since matriculation or other examination entitling to registration as a medical student.*

The *Matriculation Examination* takes place thrice yearly—in January, June (or July), and September. Application for admission to it must be made on a special form about six weeks beforehand, and the candidate must have completed his 15th year at the date of the examination. Candidates must show a competent knowledge of five subjects, among which

* May obtain registration as Internal or External students on presentation of documentary evidence as to their condition and a payment of £2: Graduates of such British, Colonial, and foreign Universities as are approved by the Senate for that purpose, and those who have passed all the examinations required for a degree in those Universities, also women who have obtained Tripos certificates granted by the University of Cambridge, and women who have obtained certificates showing that, under the conditions prescribed by the Delegacy for Local Examinations at Oxford, they have passed the Second Public Examination of that University or have obtained honours in the Oxford University Examination for Women in Modern Languages, and students who hold the Scotch School Leaving Certificate, having passed on one and the same occasion, in the Higher or Honours Grade in all the subjects required by the regulations for the Matriculation Examination.

must be English and elementary mathematics. The other three (one of them a language) may be selected from the following:—Latin, Greek, French, German, Arabic,* Sanscrit,* Spanish,* Portuguese,* Italian,* Hebrew,* Ancient History, Modern History, Logic, Physical and General Geography, Geometrical and Mechanical Drawing, Mathematics (more advanced than in the compulsory examination), Elementary Mechanics, Elementary Chemistry, Elementary Biology (Botany), Elementary Biology (Zoology),* Elementary Physics, Heat, Light, and Sound, Electricity, and Magnetism. Candidates who desire to be examined in the subjects against which an asterisk is affixed must give at least two months' notice.

The *Preliminary Scientific Examination* will take place twice in each year, in January and July. It will consist of papers in chemistry, biology, and physics, and there will be a practical examination in each subject. Examiners will also be at liberty to test candidates *viva voce*. A student may present himself for examination in each of the three subjects, separately or in all at the same time. Part I. of this examination includes papers in inorganic chemistry, physics, and biology, with practical examinations; Part II. is an examination in organic chemistry.

The *Intermediate Examination in Medicine* will take place twice a year, January and July. Candidates must have passed the Preliminary Scientific Examination at least two years previously. The subjects of examination are Anatomy, Physiology and Histology, and Pharmacology, including *Materia Medica*. Candidates who have failed in one subject only at this examination may offer themselves for re-examination in that subject, if permitted to do so by the examiners. Three scholarships, one of the value of £40 in Anatomy, another of the same amount in Physiology, and one of £30 in Pharmacology may be awarded by the examiners to any candidate who has passed the whole of the examination at one time.

Provincial Examinations for Matriculation.—These examinations are appointed by the Senate from time to time upon the application of any city, institution, or college desiring to be named as a local centre for one or more examinations in London under the supervision of sub-examiners also appointed by the Senate. Candidates wishing to be examined at any centre must give notice upon their forms of entry to the Principal of the University. Besides the University fee a fee usually varying from £1 to £3 is charged by the local authorities and must be paid at the local centre before the commencement of the examination.

The *Final M.B., B.S., Examination* will take place twice a year, in October and May. No candidate will be admitted to this examination unless he has completed the course of study prescribed in the schedule or in less than two academic years from the date of passing the Intermediate Examination in anatomy and physiology.

The subjects of the examination are Medicine (including Therapeutics and Mental Diseases), Pathology, Forensic Medicine and Hygiene, Surgery, and Midwifery and Diseases of Women. The subjects may be divided into two groups, one of which shall comprise Medicine, Pathology, Forensic Medicine and Hygiene; and the other Surgery, Midwifery and Diseases of Women. Either group may be taken first at the option of the candidate, or the groups may be taken together.

Only candidates who show a competent knowledge of all the subjects comprising a group will be passed. The examiners will be empowered to recommend the award of a University Medal to the candidate who has most distinguished himself in the whole examination.

Doctor of Medicine.—The examination for the degree of Doctor of Medicine will be held twice in each year, in December and July. Every candidate must have passed the examination for the M.B., B.S., of this University. Candidates may present themselves for examination in one of the following branches: (1) Medicine, (2) Pathology, (3) Mental Diseases, (4) Midwifery and Diseases of Women, (5) State Medicine; and if they wish, may pass also in another branch at a

subsequent examination. Candidates for Branches 1 to 4 who have taken honours at the M.B., B.S., examination in the subject in which they present themselves for the M.D. degree, or who, subsequently to taking the M.B., B.S., have conducted a piece of original work approved for the purpose by the University, or have had special experience approved by the University, may present themselves for the M.D. examination one year after taking their Bachelor's degree. Other candidates must show that they have taken the degree of M.B., B.S., not less than two years previously; and as regards candidates in Branches 1 to 4, that subsequently to taking that degree they have held for at least six months a resident or non-resident medical hospital appointment, or that they have been in qualified practice for not less than five years, while candidates in Branches 2 and 3 must show that they have held in the one case a pathological and in the other an asylum appointment. In each branch there will be (1) two papers on the special subject of the branch; (2) a clinical examination; (3) an essay to be written on one of two given subjects connected with the branch. In Branch 1 there will also be a paper on pathology, and in Branches 2, 3, and 4 a paper in medicine, while in Branch 2 a laboratory examination will be substituted for the Clinical Examination held in the other branches.

Candidates in Branch 5 (State Medicine) must show that they have taken the degrees M.B., B.S. not less than two years previously, and that subsequently to taking those degrees they have had (1) six months' practical instruction in an approved laboratory; (2) six months' practical instruction from a medical officer of health, of which three must not coincide with the laboratory work, and three months' practice at a hospital for infectious diseases. The interval between passing the M.B., B.S. and proceeding to the M.D. State Medicine may be reduced to one year, subject to conditions corresponding to those affecting Branches 1, 2, 3, and 4.

Master of Surgery.—The examination for the degree of Master in Surgery will take place twice in each year, commencing on the same dates as the foregoing, and the general regulations already quoted with regard to the M.D. will practically apply to it, surgery being substituted for medicine. The examination will consist of (1) two papers on surgery (one of which may be a case for commentary); (2) an essay to be written on one of two subjects which may be selected from any branch of surgery; (3) two papers on surgical pathology and surgical anatomy; (4) a clinical examination; (5) operations on the dead body; (6) a *viva voce* at the discretion of the examiners. Competent knowledge in every subject of the examination must be shown in order to pass.

For the M.S. degree and all branches of the M.D. a candidate is at liberty to forward a thesis or copies of published works embodying the result of independent research in the subject in which he presents himself for a degree and also any printed contributions to the advancement of professional knowledge published either separately or conjointly. If the examiners consider such thesis or works of sufficient merit they are empowered to exempt a candidate partly or entirely from examination in the subject to which such work refers. They also have power to award a University Medal to the candidate who at the examination in any branch passes with most distinction.

Fees.—This University has established centres for preliminary and intermediate studies at University and King's Colleges. The fees for the courses at these colleges are arranged in two scales:—(a) For courses required by the University of London. 1. Preliminary scientific (Part I.) course, fee £26 5s. Repetition (practical and lectures), fee £4 4s. per subject (physics, chemistry, botany, and zoology); attendance for one year. 2. Preliminary scientific (Part II.) course and Intermediate course, fee £57 15s. in one sum, or £63 in two instalments; attendance, anatomy, and physiology (with one in each course of practical physiology) during three years, and one in organic chemistry (Preliminary Scientific, Part II.), pharmacology, and

materia medica. Repetition: Fees £3 3s. for physiology and anatomy and £4 4s. for other subjects; attendance for three months. (b) For courses for examinations by the Conjoint Board. 1. First examination (Parts I., II., and III.) course, fee £21. Repetition (chemistry, physics, and biology), fee £3 3s. 2. First examination (Part IV.) course and second examination course, fees £57 15s. in one sum, or £63 in two instalments; attendance for three years, with one at practical physiology courses. Repetition (practical physiology), fee £3 3s. Anatomy and physiology, fee £3 3s. for each subject; attendance for every three months' work beyond the three years. Students may enter these courses either through the medical schools at present connected with these centres or through St. George's Hospital Medical School or Westminster Hospital Medical School; they may also enter these centres directly and choose their medical school subsequently. Information on these points may be had of the Academic Registrar, University of London, South Kensington.

UNIVERSITY OF DURHAM.

One diploma and six degrees in Medicine and Hygiene are conferred, *viz.*, the degrees of Bachelor in Medicine, Bachelor in Surgery, Master in Surgery, Doctor in Medicine, Bachelor in Hygiene, and Doctor in Hygiene, and Diploma in Public Health. These degrees are open to both men and women.

For the degree of Bachelor in Medicine (M.B.) there are four professional examinations. The subjects for the first are: Elementary anatomy and elementary biology, chemistry, and physics. For the second: Anatomy, physiology, materia medica, therapeutics, and pharmacology. For the third: Pathology, medical jurisprudence, public health, and elementary bacteriology; and for the fourth: Medicine, clinical medicine and psychological medicine, surgery and clinical surgery, midwifery, and diseases of women and children.

It is required that one of the five years of professional education shall be spent in attendance at the University College of Medicine and the Royal Infirmary, Newcastle-upon-Tyne. First and second year students (dating from registration) are not required to comply with the regulation regarding attendance on hospital practice. Candidates who have passed the First and Second Examinations of the University will be exempt from the First and Second Examinations of the Conjoint Board.

For the degree of Bachelor in Surgery (B.S.) every candidate must have passed the examination for the degree of Bachelor of Medicine of the University of Durham, and must have attended one course of lectures on operative surgery, and one course on regional anatomy. Candidates will be required to perform operations on the dead body, and to give proof of practical knowledge of the use of surgical instruments and appliances.

For the degree of Master in Surgery (M.S.) candidates must not be less than twenty-four years of age, and must satisfy the University as to their knowledge of Greek or German. In case they shall not have passed in either of these subjects at the Preliminary Examinations in Arts for the M.B. degree, they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they can proceed to the higher degree of M.S. They must also have obtained the degree of Bachelor in Surgery of the University of Durham, and must have been engaged for at least two years subsequently to the date of acquirement of the degree of Bachelor in Surgery in attendance on the practice of a recognised hospital, or in the naval or military service, or in medical or surgical practice.

For the degree of Doctor in Medicine (M.D.) candidates must be of not less than twenty-four years of age, and must satisfy the University as to their knowledge of Greek or German. In case they shall not have passed in either of these subjects at the Preliminary Examinations in Arts for the M.B. degree,

they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they proceed to the higher degree of M.D. They must also have obtained the degree of Bachelor of Medicine of the University of Durham, and must have been engaged for at least two years, subsequently to the date of acquirement of the degree of Bachelor of Medicine, in attendance on the practice of a recognised hospital or in the naval or military services, or in medical or surgical practice.

Each candidate must present an essay which has been prepared entirely by himself, and which must be typewritten, based on original research or observation, on some medical subject selected by himself, and approved by the Professor of Medicine, and must pass an examination thereon, and must be prepared to answer questions on the other subjects of his curriculum, so far as they are related to the subjects of the essay.

For regulations for degrees in Hygiene and for the diploma in Public Health see Calendar 1905-6.

Candidates for any of the above degrees must give at least twenty-eight days' notice to the Secretary of the College of Medicine, Newcastle-on-Tyne. In the case of the M.D. (Essay) Examination, candidates must send in their essays six weeks before the date of the examination.

Attached to this University for the acquirement of medical study and hospital practice, is the Royal Infirmary, a very commodious and ornate building, with 280 beds. A new wing is in course of erection, which will accommodate the departments of physiology and bacteriology, and contain a students' gymnasium and a set of students' union rooms, and will be completed by the summer of 1906. Pathological demonstrations are given as opportunity offers. The New Royal Victoria Infirmary, containing 450 beds, is approaching completion, and will be opened in the course of next summer. In the new infirmary adequate accommodation will be provided for the study of the various special subjects, in addition to the ordinary clinical work. Practical midwifery can be studied at the Newcastle Lying-in Hospital. Opportunities for practical study are also afforded by the Dispensary, City Infectious Diseases Hospital, Eye Infirmary, and at the Northumberland County Lunatic Asylum.

There are various appointments open to the students, some carrying with them an honorarium, whilst the scholarships available are numerous and of considerable value.

Fees.—(a) A composition ticket for lectures at the college may be obtained—1. By payment of 72 guineas on entrance. 2. By payment of 46 guineas at the commencement of the first sessional year and 36 guineas at the commencement of the second sessional year. 3. By three annual instalments of 36, 31, and 20 guineas, respectively, at the commencement of the sessional year. (b) Fees for attendance on hospital practice: For three months' medical and hospital practice, five guineas; for six months, eight guineas; one year, twelve guineas composition fee in one payment, twenty-five guineas; or by three instalments at the commencement of the sessional year, *viz.*, first year, 12 guineas; second year, ten guineas; third year, six guineas; or by two instalments, *viz.*, first year, fourteen guineas; second year, twelve guineas. In addition, two guineas yearly up to three years must be paid to the Committee of the Royal Infirmary.

Residence can be had in a separate hostel for female students at moderate inclusive fees for board, &c., particulars of which and any other college information will be given on application to Prof. Howden, Secretary, University of Durham College of Medicine, Newcastle-on-Tyne.

MANCHESTER UNIVERSITY.

Candidates for degrees in medicine and surgery must attend classes in the University during at least two years.

The degrees in the Faculty of Medicine are Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.).

Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). All candidates for degrees in medicine and surgery are required to pass the Matriculation Examination, or to have passed such other examination as may from time to time be recognised for this purpose by the University.

The subjects of the Matriculation Examination are—1, Latin; 2, mathematics; 3, mechanics; 4, English and history; 5, one of the following:—(a) French; (b) German; (c) Greek; (d) Italian; (e) Spanish; (f) any other modern language, permission to present which has been obtained from the Joint Matriculation Board. Notice of intention to present either Italian or Spanish must be given to the Secretary, Joint Matriculation Board, Manchester, before March 1st in each year.

Before admission to the degrees of Bachelor of Medicine and Surgery candidates are required to send in the usual certificates of age and study as at the other Universities. All candidates for these degrees must pass three examinations, and must have attended courses of both lectures and laboratory work.

The final examination is divided into two parts, which may be passed separately or on the same occasion, but the first part cannot be taken before the end of the third year, and the second part cannot be taken less than two years after passing Second M.B., or before the fifth year of medical study in accordance with the University regulations. The subjects of examination are as follows: 1, Pharmacology and therapeutics; 2, General pathology and morbid anatomy; 3, Forensic medicine and toxicology and public health; 4, Obstetrics and diseases of women; 5, Surgery, systematic, clinical, and practical; 6, Medicine, systematic and clinical, including mental diseases and diseases of children. Candidates may select as a first part of the examination two or three of the subjects 1, 2, and 3.

The certificates required from candidates at the final examination are practically the same as for the corresponding examination at the London University, and only those who have previously passed the Second Examination are admitted to it. The regulations relating to the M.D. and Ch.M. degrees can be obtained on application to the Registrar.

Fees.—Matriculation examination, £2; for any subsequent examination, £1. First Examination, £5; for any subsequent examination, £2. The fees for the Second Examination, for the Final Examination, and for the examination for the degree of Ch.M. are the same as for the First Examination. A fee of £10 is payable on the conferring of the degree of M.D., a fee of £4 on the conferring of the degree of Ch.M.

The Matriculation Examination is held in June, in July (for schools), and about the end of September. The first M.B. and Ch.B. is held in June; also about the end of September. The Second and Final Examinations are held in March and July, the examination for Ch.M. in July only.

The medical school buildings, which include large laboratories, dissecting-rooms, library and reading-rooms, are on the most modern principles, and students wishing to engage in anatomical, physiological, or pathological research will find excellent opportunity for study in the complete and well-furnished laboratories. Hospital practice is taken out at the Royal Infirmary, which contains 300 beds. The Cheadle Lunatic Asylum, St. Mary's Hospital, the Southern Hospital, and other special hospitals also afford teaching facilities of great importance.

The appointments open to students are numerous and of considerable monetary value, and there are probably more here than are available at any other medical centre. The principal are:—Nine Entrance scholarships, the Leech fellowship of £100; Entrance scholarships in medicine, £100 (towards College and Infirmary fees); Manchester Grammar School scholarships, two or three of not less than £15 or more than £30 per annum for three years; Turner scholarship of £20 to students who have completed a course of medical study in the University; Platt physiological scholarships, two of the value of £50 each; Platt zoological

and botanical scholarship, £50; Professor Tom Jones' memorial surgical scholarship of £100, awarded triennially; two Dauntsey medical entrance scholarships, value £35; John Henry Agnew scholarship in diseases of children, value £30, awarded annually; Graduate scholarship in medicine, £25 to £50, awarded annually; and many others.

Fees.—Composition fee, £80, in two sums of £40 each. Hospital practice: Composition fee, £42, or two instalments of £22 each.

Dental Fees.—Composition fee, £57 15s., payable in two sums of £28 17s. 6d. each. Hospital practice, £21.

BIRMINGHAM UNIVERSITY.

The University of Birmingham grants degrees of M.B., Ch.B., M.D., Ch.M., and also a B.Sc. in the subject of Public Health. As a rule, in order to obtain any of these degrees it is necessary that a student shall have passed at least the first four years of his curriculum in attendance upon the classes of the University, but the Senate has power of recognising attendance at another University as part of the attendance qualifying for these degrees.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—The student must have passed either the Matriculation Examination of the University or one of the following examinations, which will be accepted in lieu thereof for the present:—(a) The previous examination of the University of Cambridge; (b) Responsons of the University of Oxford; (c) The matriculation examination of any other University in the United Kingdom; (d) The leaving certificate (higher) of the Oxford and Cambridge Boards; (e) The Oxford or Cambridge junior local examination (first or second class honours); (f) The Oxford or Cambridge senior local examination (honours); (g) The College of Preceptors examination for first-class certificate.

Matriculation Examinations are held in June and September each year.

Degrees of Doctor of Medicine and Master of Surgery.—At the end of one year from the date of having passed the Final M.B., Ch.B. Examination, the candidate will be eligible to present himself for the higher degrees of either Doctor of Medicine or Master of Surgery or both, the regulations for which may be had upon application to the Registrar. The University also grants a Degree and a Diploma in Public Health, and provides adequate instructions for the same.

Dental Department.—The University grants the Degrees of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.), and a Diploma in Dental Surgery (L.D.S.). The whole of the instruction for which may be taken out in the University, with which is associated the Birmingham Dental Hospital.

THE GENERAL AND QUEEN'S HOSPITALS.—The practices of these hospitals are amalgamated for the purpose of clinical instruction under the direction of the Birmingham Clinical Board, by whom all schedules will be signed and all examinations conducted. The hospitals have a total of upwards of 400 beds. 6,000 in-patients and 80,000 out-patients are treated annually, and many valuable posts are open to students at both.

Further information can be obtained from Professor Gilbert Barling, Dean, Medical Faculty.

UNIVERSITY OF LIVERPOOL.

The Degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The course of study for the degrees of Bachelor of Medicine and Bachelor of Surgery is of five years' duration, and of this period two years must be spent at the University, the remaining three years can be taken in any medical school approved by the University.

The University provides a complete curriculum for these Degrees, and possesses modern and well-equipped laboratories and class-rooms for the teaching of all the subjects.

For the Degree of M.D., a thesis is required which may be presented not earlier than one year after graduation, as M.B., Ch.B.

The degree of Ch.M. is given after a period of at least one year of further study after graduation as M.B., Ch.B., on the results of an examination.

The University also confers Diplomas in Public Health (D.P.H.) and Tropical Medicine (D.T.M.) upon qualified medical practitioners who have studied these subjects in the University and passed the prescribed examinations.

A Diploma (L.D.S.) and Degrees (B.D.S. and M.D.S.) have recently been instituted in dental surgery. These are only conferred upon students of the University. Particulars may be obtained from the Registrar.

Students may enter for the degrees of the University of Liverpool, or may study for the degrees and qualifications of the other licensing bodies.

Hospitals.—Students may take out their clinical work at the Liverpool Royal Infirmary, or at the United Hospitals Clinical School, which has been formed by the David Lewis Northern Hospital, the Royal Southern Hospital, and the Stanley Hospital. Particulars as to fees, appointments, &c., may be obtained from the Secretaries of these schools. The practice of the Lying-in, Eye and Ear, Women's, Children's, Dental, and Skin Hospitals is also open to students of the Faculty of Medicine.

Fellowships and Scholarships.—Fellowships, Scholarships, and Prizes of over £800 are awarded annually. A Holt Fellowship in Pathology and Surgery, of the value of £100 for one year, is awarded annually by the Medical Faculty to a senior student possessing a medical qualification. The successful candidate is required to devote a year to tutorial work and investigation in the Pathological department. A Holt Fellowship in Physiology, awarded under similar conditions, also of the value of £100 for one year. A Robert Gee Fellowship in Anatomy, awarded under similar conditions, of the value of £100 for one year. An Alexander Fellowship for Research in Pathology of the annual value of £100, renewable. A Johnson Colonial Fellowship in Pathology and Bacteriology (£100 a year, renewable). A John W. Garrett International Fellowship in Physiology and Pathology (£100 a year, renewable). An Ethel Boyce Fellowship in Gynæcological Pathology (£100 a year, renewable). A Stopford Taylor Fellowship (£100 a year, renewable) in Dermatological Pathology. A Thelwall Thomas Fellowship (£100 a year, renewable) in Surgical Pathology. Two Lyon Jones scholarships, of the value of £21 each for two years, are awarded annually—a Junior Scholarship, open at the end of the first year of study to Liverpool University students in the subjects of the first M.B. Examinations, and a Senior Scholarship, open to all students in the school at the end of the second or third year of study, in the subjects of Anatomy, Physiology, and Therapeutics. The Derby Exhibition of £15 for one year is awarded in Clinical Medicine and Surgery in alternate years. Students may compete in their fourth and fifth years. In 1904 the subject will be Clinical Medicine. The Torr Gold Medal in Anatomy, the George Holt Medal in Physiology, the Kanhack Medal in Pathology, and the Robert Gee Book Prize, of the value of £5, for Children's Diseases.

Entrance Scholarships.—Two Robert Gee Entrance Scholarships, of the annual value each of £25 for two years, are offered annually for competition. The holder is required to take out the Science Course for the University Degree in Medicine.

Communications should be addressed to the Dean, Professor Benjamin Moore, M.A., D.Sc., the University, Liverpool.

THE ENGLISH COLLEGES.

The medical corporations in England are the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries of London. The two Royal Colleges now co-operate to hold a series of examinations, on passing which the candidate receives the diploma of Licentiate of the Royal College of Physicians (L.R.C.P.), and Member of the Royal College of Surgeons (M.R.C.S.). The Society

of Apothecaries grants a complete diploma in medicine, surgery, and midwifery.

CONJOINT EXAMINING BOARD IN ENGLAND.

Candidates for the above licences are required to complete five years of professional study at recognised medical schools and hospitals, after passing the preliminary examination, of which six months may be spent at an institution recognised by the Board for instruction in chemistry, or one year may be passed at an institution recognised by the Board for instruction in chemistry and biology, to comply with the following regulations and to pass the examinations hereinafter set forth.

Professional Examinations.—There are three examinations, each being partly written, partly oral, and partly practical. These examinations will be held in the months of January, April, July, and October, unless otherwise appointed, fourteen clear days' notice before the day on which the examination commences being required, the candidate transmitting at the same time the required certificates.

The subjects of the first professional examination are chemistry and physics, practical pharmacy, and elementary biology. A candidate is allowed to take this examination in three parts at different times. Rejection entails a delay of not less than three months from the date of rejection, and the candidate will be re-examined in the subject or subjects in which he has been rejected. If referred in chemistry or biology, he must produce evidence of further instruction at a recognised institution. Practical pharmacy may be passed at any time during the curriculum. Any candidate who shall produce satisfactory evidence of having passed an examination for a degree in medicine on any of the subjects of this examination conducted at a University in the United Kingdom, India, or in a British Colony, will be exempt from examination in those subjects in which he has passed.

The fees for admission to the first examination are as follows:—For the whole examination, £10 10s.; for re-examination after rejection in Part I., £3 3s.; and for re-examination in each of the other parts, £2 2s.

The subjects of the second examination are anatomy and physiology. Candidates will be required to pass in both subjects at one and the same time. Candidates will be admissible to the second examination at the expiration of two winter sessions and one summer session (or fifteen months during the ordinary sessions) from the date of registration as medical students, and after the lapse of not less than nine months from the date of passing Parts I. and III. of the first examination.

A candidate referred at the second examination will be required, before being admitted to re-examination, to produce a certificate that he has pursued, to the satisfaction of his teachers, in a recognised place of study, his anatomical and physiological studies during a period of not less than three months subsequently to the date of his reference.

The fees for admission to the second examinations are: £10 10s. for the whole examination, and £6 6s. for re-examination after rejection.

The subjects of the third and final examinations are:—Part I. Medicine, including medical anatomy, pathology, practical pharmacy, therapeutics, forensic medicine and public health. Candidates who have passed in practical pharmacy at the first examination will not be re-examined in that subject at the third examination. Part II. Surgery, including pathology, surgical anatomy, and the use of surgical appliances. Part III. Midwifery and gynæcology. Candidates may take this examination in three parts separately, or they may present themselves for the whole examination at one time.

Fees for admission to the third or final examination are as follows:—For the whole examination, £21 0s. Part I.—For re-examination in medicine, including medical anatomy, pathology, therapeutics, forensic medicine, and public health, £5 5s.; for re-examination in practical pharmacy (if taken at this examination), £2 2s. Part II.—For re-examination in surgery, including pathology, surgical anatomy, and the use of surgical

appliances, £5 5s. Part III.—For re-examination in midwifery and gynaecology, £3 3s.

A candidate referred on the third or final examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and will be required, before being admitted to re-examination, to produce a certificate, in regard to medicine and surgery, of having attended the medical and surgical practice, or the medical or surgical practice, as the case may be, during the period of his reference; and in regard to midwifery and diseases peculiar to women a certificate of having received, subsequently to the date of his reference, not less than three months' instruction in that subject by a recognised teacher.

REGULATIONS FOR COLONIAL, INDIAN, AND FOREIGN CANDIDATES, AND UNIVERSITY CANDIDATES.

Persons holding a Colonial, Indian, or a foreign qualification entitling them to practise medicine in the country of origin, and conferred after a course of study and examinations equivalent to those required by the Royal Colleges, are admissible to the second and third (final) examinations forthwith.

Members of a University in the United Kingdom are, under certain conditions, eligible for admission to the third (final) examination two years after passing at their University in the subjects included in the first and second examinations of the Board.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

Members.—The membership of the College is granted after examination to persons above the age of 25 years who do not engage in trade, do not dispense medicine, and do not practise in partnership. This diploma is only granted to persons already registered, or who have passed the final examination for the licence.

Medical graduates of a recognised University are admitted to a pass examination, but others must have passed the examinations required for the licence of the College. The examination, which is held in January, April, July, and October, is partly written and partly oral. It is directed to medicine, and is conducted by the president and censors. Candidates under 40, unless they have obtained a degree in arts in a British University, are examined in Latin, and either Greek, French, or German. Candidates over 40 are not so examined, and the examination in medicine may in their case be modified under conditions to be ascertained by application to the Registrar. The fee for the membership is £42, but if the candidate is a licentiate £15 5s. is deducted. In either case £6 6s. has to be paid before examination.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEMBERSHIP.—The candidates are now subject to the regulations of the Conjoint Board.

FELLOWSHIP.—The Fellowship of the College of Surgeons is granted after examination to persons at least 25 years of age, who have been engaged in professional studies for six years. There are two examinations—the first in anatomy and physiology, which may be passed after the third winter session; the second chiefly directed to surgery, which may be passed after six years of professional study. The second examination may be passed before attaining the age of 25, but the diploma is not granted until that age is reached. Candidates for this part of the examination must have passed the final examination of the Conjoint Board in England, and have been admitted members of the College before they can be admitted thereto, except in the case of graduates in medicine and surgery of recognised Universities of not less than four years' standing.

FEES.—First examination, £5 5s.; second examination, £12 12s. The total fee payable on admission to the Fellowship is £31 10s., except for members, when the fee is £21. (The examination fees to the extent of £17 17s. count as part of the total fee.) Further information can be obtained on application to the Secretary of the Royal College of Surgeons, Lincoln's Inn Fields, London, W.C.

There are two examinations—primary and final.

The primary examination is held quarterly on the first Wednesday, and on the Monday and Tuesday in the same week, in the months of January, April, July, and October. The final examination is held monthly.

SOCIETY OF APOTHECARIES OF LONDON.

PRIMARY EXAMINATION.—This examination consists of two parts: Part I.—Elementary biology, Chemistry, Chemical physics, including the elementary mechanics of solids and fluids; Heat, Light, and Electricity. Practical chemistry, Materia medica, and Pharmacy. A synopsis indicating the range of the subjects may be obtained on application. Part II.—Anatomy and Physiology and Histology. The examination is held in January, April, July, and October.

The final examination is held monthly, and is divided into Sections 1 and 2.

Section 1 consists of three parts.

Part I. includes: Principles and Practice of Surgery, Surgical Pathology, and Surgical Anatomy, Operative Manipulations, Instruments and Appliances.

Part II. includes: (a) The Principles and Practice of Medicine, including Therapeutics, Pharmacology, Pathology, and Morbid Histology. (b) Forensic Medicine, Hygiene, Theory and Practice of Vaccination; and Mental Diseases.

Candidates passing either (a) or (b) will not be re-examined therein.

Part III. includes: Midwifery, Gynaecology, and Diseases of New-born Children, Obstetric Instruments and Appliances. Candidates may enter for Parts I., II., and III. together or separately.

Section 1 of the Final Examination, or any part thereof, cannot be passed before the expiration of 45 months from the date of registration as a medical student.

Section 2.—This section consists of two parts:

Part I.—Clinical Surgery;

Part II.—Clinical Medicine and Medical Anatomy. Section 2 cannot be passed before the expiration of the fifth year.

FEES.—Primary examination, £5 5s.; final examination, £15 15s.; total fee, £21.

Further information, with particulars as to the course of study and of the certificates required, can be obtained from the Secretary to the Court of Examiners, Apothecaries' Hall, E.C.

This licence is a registrable diploma in Medicine, Surgery, and Midwifery, and qualifies the holder to compete for medical appointments in the Army, Navy, and Indian Services, also for Poor-law, Civil, and Colonial appointments.

The Gillson scholarship in Pathology of the annual value of £90, tenable for one year, is open to Licentiates of the Society and to candidates for the diploma who obtain it within six months of election to the scholarship. An examination in the art of prescribing is held annually, in January, at which the following prizes are awarded:—A gold medal of the value of £6; a silver medal, and a prize of books to the two best candidates.

LONDON SCHOOLS.

The Schools of Medicine in the Metropolis are the following: the scholarships, prizes, students' appointments, fees, &c., being set forth in connection with each place named. The names of the hospital staff, lecturers, residential terms, and detailed information will be found, as a rule, in our advertisement columns.

ST. BARTHOLOMEW'S HOSPITAL.—This hospital has 750 beds, and for many years past the school attached has had a larger number of students than any other medical school in London. Laboratories have been specially equipped for the study of pathology, bacteriology, chemistry, biology, physics, and chemical pathology, and two additional operation theatres have just been built. A new block of buildings is in course of erection at a cost of £120,000, and will contain new casualty and out-patients' departments, eight special departments, quarters for the junior staff, a dining hall and a common room for students, &c.

Collegiate residence is permissible, subject to the ordinary rules.

Appointments.—Ten house physicians and ten house surgeons are appointed annually. During the first six months of office they act as "junior" house physicians and house surgeons, and receive a salary of £25 a year. During their second six months they become "senior" house physicians and house surgeons, and are provided with rooms by the hospital authorities, and receive a salary of £80 a year. A resident midwifery assistant and an ophthalmic house surgeon are appointed every six months, and are provided with rooms and receive a salary of £80 a year. Two assistant anaesthetists are appointed annually, and receive salaries of £120 and £100 a year respectively. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. Chief assistants and clinical assistants are appointed in each of the special departments. In-patient dressers, in-patient clinical clerks, clerks, and dressers to the assistant physicians, and assistant surgeons, and to the physicians and surgeons in charge of special departments, are appointed every three months without fee.

Scholarships, &c.—There are four open scholarships in science, £75, £75, £150, £50, tenable for one year, and a Jeaffreson exhibition, value £20; at the end of first year four junior scholarships of £30, £20, £25, £15, respectively; Treasurer's prize for practical anatomy; Föster prize in practical anatomy; senior scholarship, value £50, for anatomy, physiology, and chemistry; Wix prize, Hichens prize, Lawrence scholarship and gold medal, value 40 guineas, for medicine, surgery, and midwifery; two Brackenbury scholarships, of £30, in medicine and surgery; Bentley prize, for reports of cases; the Kirkes gold medal for clinical medicine, with scholarship of £30. Shuter scholarship of £50; Skyner prize of £15; Sir G. Burrows' prize of £10; Matthews Duncan prize, medal and about £20; Willett medal and Walsham prize; Holden Research Scholarship in Surgery, value £105.

Fees.—By payment of an annual composition fee, a student is entitled to attend all the courses of instruction, and to hold the various clinical appointments. For students commencing their medical studies:—Entrance fee, 30 guineas; annual fee, 30 guineas, for five years, or a single payment of 165 guineas. A student on qualification at the end of the five years is not liable for any further fees, and receives a perpetual ticket. Should he fail to qualify in this time, the fee for further instruction is 10 guineas for each six months. Fees for University students:—Entrance fee, 20 guineas; 30 guineas, annually for two years, and 10 guineas for each six months if not qualified. Fees for preliminary scientific students:—20 guineas; for laboratory instruction for D.P.H., 15 guineas.

The Warden, Mr. W. D. Harmer, will furnish further details on application.

CHARING CROSS HOSPITAL.—The school attached to this hospital is situated in central London, and contains new physiological, pathological, and bacteriological laboratories, materia medica and anatomical museums, an anatomical theatre, enlarged dissecting-room, and chemical theatre. Clinical instruction is given in medicine, surgery, and obstetrics, and in the special department, diseases of the skin, diseases of children, mental disorders, the throat, the eye, nose and ear, and in the orthopaedic, Röntgen, and electrical departments, there are several scholarships and prizes, particulars of which can be obtained of the Dean.

Appointments.—The curator and pathologist is appointed annually, and receives £100 a year; medical and surgical registrars to the hospital receive £40 a year each, with luncheon in the hospital; obstetric registrar, six house physicians, six house surgeons, and two resident obstetrical officers are appointed each year; clinical clerks and dressers are appointed in all the general and special departments of the hospital.

Fees.—For the curriculum of study required by the various examining bodies and hospital practice, 115

guineas in one sum, or 126 guineas in five instalments.

The composition fee for sons of registered medical practitioners is 105 guineas, and the fee, by instalments, 115 guineas. For dental students, 55 guineas in one sum, or 61 guineas payable in two instalments of 31 and 30 guineas respectively.

ST. GEORGE'S HOSPITAL.—This hospital is situated in the West End, facing Hyde Park. It contains 351 beds, and special wards for ophthalmic cases and diseases of women.

Appointments.—Eight house physicians and eight house surgeons, entitled to reside and board in the hospital free of expense; twelve general assistants, six assistants in the special departments. Candidates for the above offices are selected quarterly by competition from among the perpetual pupils, sixteen pupils being in office at any one time. Obstetric assistant with a yearly salary at the rate of £50 and board and residence in the hospital; curator of the museum with a salary of £200; assistant curator with a salary of £100; two medical registrars, with salaries of £200 per annum; a surgical registrar with a salary of £200 per annum; an administrator of anaesthetics with a salary of £50 and two with salaries of £30 per annum; a surgery officer with a salary of £100 a year; two or more demonstrators of anatomy with a salary of £50 each; and assistant demonstrators. All offices are open to candidates without additional fee.

There are various scholarships and exhibitions open to students, particulars of which will be furnished by the Dean.

Fees.—Entrance fee, 20 guineas; annual composition fee, 30 guineas; prel. sci. fee, 16 guineas, with an additional 4 guineas for expenses. In the event of study for the preliminary scientific or corresponding examinations being carried out at this school, the fee of 16 guineas will be regarded as part of the entrance fee. Entrance fee for University students, 10 guineas.

GUY'S HOSPITAL.—This hospital is situated on the Surrey side of London Bridge, and contains 602 beds in constant occupation. There are special wards for ophthalmic and obstetric cases, eight beds in the latter being appropriated for difficult cases of labour. Some beds have also been set apart for diseases of the ear and throat, and an "isolation" ward for cases of infectious diseases arising in the hospital has been constructed. An obstetric registrar and tutor and an ophthalmic registrar and tutor are appointed to augment the teaching in the special departments, in addition to those attached to the general surgical and medical wards. Attached to the hospital is a large residential college with rooms for about sixty men, whilst for students who prefer to live in the suburbs, no other hospital is so conveniently placed, the railway accommodation being good and close at hand. There is a complete School of Dental Surgery at this Institution, which is recognised by the Royal College of Surgeons of England; the facilities thus afforded of completing the whole course of dental study within the walls of one hospital will be appreciated by those intending to practise dentistry. A new museum for pathological specimens and additional lecture and class rooms were opened this year.

Appointments.—Eight house surgeons, eight house physicians, eight assistant house physicians, twenty-four assistant house surgeons, eight obstetric residents, two ophthalmic house surgeons, twenty-four clinical assistants, and ninety-six dressers are selected annually from the students according to merit, and without payment. There are also a large number of junior appointments, every part of the hospital practice being systematically employed for instruction.

Scholarships.—Open scholarships of £100 and £50 in classics, mathematics, and modern languages. Open scholarships of £150 and £60 in chemistry, physics, and biology, and an open scholarship of £50 for University students in two of the following subjects:—Anatomy, physiology, organic chemistry, zoology, physics. The following are the scholarships, prizes, and medals open to students of the hospital:—The Arthur Durham

prizes for dissection, £15 and £5; Junior prizes for general proficiency, £20, £15, £10; Hilton prize for dissection, £5; Michael Harris prize for anatomy, £10; Sands Cox scholarship for physiology, £15; Wooldridge prize for physiology, £10; Beaney prize in pathology, £34; Golding-Bird prize in bacteriology, gold medal and £20; Treasurer's gold medal in clinical medicine; Treasurer's gold medal in clinical surgery; Beaney studentship in materia medica (tenable for 3 years), annually £31 10s.; Gull studentship in pathology (tenable for 3 or 5 years), annually £150.

Fees.—A new system for payment of composition fees has been recently instituted at this school. Particulars may be obtained on application to the Dean, Guy's Hospital, London Bridge, S.E.

KING'S COLLEGE HOSPITAL.—This hospital is centrally situated, being contiguous to the Royal College of Surgeons, Lincoln's Inn Fields. The College adjoins Somerset House and is close to the hospital, in which there are 220 beds available for clinical teaching; ophthalmic, ear, throat, skin, and dental departments are attached to the hospital. Some wards are specially devoted to children's diseases. The wards have been recently refloored and the electric light is installed throughout.

Scholarships.—Two scholarships of the value of £100 each; a scholarship, value £50, is open to students of a British University who come up to London to complete their curriculum; and one of £40 for fifth year students. In addition, students may compete for the Carter, Todd, Tanner prizes, and all class and clinical prizes.

Appointments.—Medical and surgical Sambrooke registrarships, tenable for two years, each £50 per annum. Resident hospital appointments, *viz.*, senior and junior house physicians, assistant house physician, physician accoucheur's assistant and assistant house accoucheur, and three house surgeons with free board and residence at the hospital; and senior and junior clinical assistants in special departments.

Special courses of lectures and practical instruction; the chemical, physical, physiological, and other laboratories have been arranged for students preparing for preliminary scientific, intermediate, science and other examinations of the University of London.

F.R.C.S. Examinations.—Special classes are arranged for the final F.R.C.S. examinations. Further particulars can be obtained from the Dean.

LONDON HOSPITAL.—This hospital is the largest in Great Britain, containing, as it does, 927 beds. It has, moreover wards and a teaching staff for almost every special department in the domain of medicine; the scholarships and prizes are many and valuable.

The additional buildings for the department of public health, for the biological, chemical, and physical laboratories, *materia medica* museum, &c., and the new bacteriological department with general laboratory, research laboratories and class rooms for D.P.H. work are now open.

Appointments.—The "House" appointments, which are numerous, are made without fee of any kind, and all resident officers are provided with free board and rooms, and in some instances with salary also.

Fees.—Perpetual fee for lectures, demonstrations and hospital practice, payable in three instalments of 45, 45, and 40 guineas at the commencement of the first, second, and third years respectively, 130 guineas; or, if in one payment, 120 guineas. Fee for students entering in their third year (their first and second years having been spent at a recognised medical school elsewhere), 60 guineas. This fee is payable by students entering who have passed the first M.B. Oxford; the second M.B. Cambridge; or the Intermediate M.B. London. Dental students (general hospital practice and lectures), 40 guineas. General fee for dental practice, 10 guineas.

Note.—A reduction of 15 guineas will be allowed to the sons of medical men from the perpetual fee if paid in full, or 5 guineas from each instalment.

Special entries can be made either for single courses

of lectures or for hospital practice. Residential accommodation is obtainable at a very reasonable rate close by, or in the suburbs a few minutes' distant by train. Fuller particulars can be obtained of the Warden, Mr. Munro Scott.

ST. MARY'S HOSPITAL.—This hospital is situated at Paddington, near the terminus of the Great Western Railway, and at present contains 281 beds. The new wing, the ground-floor of which, comprising the new out-patient department, was opened in 1898, is now completed, and will be opened as soon as funds will permit; this will raise the number of beds to 350, and will include additional operating theatres, a new clinical laboratory, a clinical theatre, and an X-ray department. An athletic ground has recently been acquired for the use of students at North Kensington (20 minutes from the hospital), and will be available for football, cricket, and lawn tennis during the coming sessions.

Appointments.—All clinical appointments in the hospital are free to students of the Medical School, and the resident medical officers are chosen by competitive examination. Six house physicians, six house surgeons, four obstetric officers, and two resident anaesthetists are appointed in each year, and receive board and residence in the Hospital.

Scholarships, &c.—One scholarship in natural science, of the value of £145, open to any gentleman who has not completed a winter session of study at a medical school. One scholarship in natural science, of the value of £78 15s., and two of £52 10s., under the same conditions. Two scholarships, each of 60 guineas, open to students from any British University. The scholarships will be awarded by examination on September 25th, 26th, and 27th.

Fees.—Fee for attendance on the full five years' curriculum of hospital practice and all lectures, demonstrations, and special tutorial classes, £140, paid in one sum on entering the school; or in instalments, £145.

Students who have completed their examinations in anatomy and physiology at the Universities of Oxford, Cambridge, or other University, are admitted as perpetual pupils on payment of a fee of 60 guineas in one sum, or 65 guineas in two annual instalments. University students, prior to completing the anatomy and physiology examinations, pay an annual fee of 25 guineas. After completing the anatomy and physiology examinations, the inclusive fee may be paid.

Preliminary Scientific Course.—A complete course of instruction in chemistry, physics, and biology, recognised by the University of London, as an approved course for internal students, is held throughout the year. Students may join in October, January, or May.

MIDDLESEX HOSPITAL.—This hospital, which is conveniently situated in the centre both of business and residential London, contains 340 beds. There are special departments for cancer, and for ophthalmic, throat, aural, skin, dental, children's diseases, and electrical treatment (X-ray and Finsen light). Wards are also devoted to cases of uterine disease. The new school buildings are now in regular use. Residence for students is obtainable in the residential college, which has its frontage on the hospital garden.

Appointments.—Casualty surgical officer, casualty medical officer, six house surgeons, six house physicians, and two resident obstetric physicians. The above officers have residence and board in the college free of expense. Clinical clerks and dressers in all the departments are also appointed in addition to the foregoing.

Scholarships, &c.—Two entrance scholarships of the value of £100 and £60 respectively. One entrance scholarship of the value of £60, open to Oxford and Cambridge students only. (Subjects—Anatomy and physiology, including histology.) "Emden" Cancer Research Scholarship, £100. "Richard Hollins." Research Scholarship, £105. Two Broderip scholarships of £60 and £40 respectively, for medicine and surgery; John Murray medal and scholarship, awarded every third year; the Governor's prize of £21 for students in their final year. Hetley clinical prize,

value £25, awarded annually for proficiency in practical clinical medicine, surgery, and obstetrics; the Lyell Gold Medal and scholarship, value £50, in surgery and surgical anatomy; the Leopold Hudson prize, value 11 guineas, in surgical pathology, including bacteriology; Freeman scholarship, £30, in obstetrics and gynaecology; exhibitions of 10 guineas and 5 guineas for anatomy and physiology to second and first year's students respectively, as well as class prizes in all subjects.

Fees.—General fee for the entire course of hospital practice and lectures, 135 guineas, if paid in one sum on entrance, or by instalments of 60, 50, and 35 guineas, payable at the commencement of the first, second, and third years respectively. For those who have completed their anatomical and physiological studies the fee is 70 guineas on entrance, or in two instalments of 40 and 35 guineas. The composition fee for London University students is 145 guineas. For those who have passed the preliminary science examination 120 guineas. The fee for the curriculum for dental students is 54 guineas on entrance, or two instalments of 40 guineas and 20 guineas.

ST. THOMAS'S HOSPITAL.—This hospital, with medical school attached, is situated on the southern Embankment of the Thames, facing the Houses of Parliament and contains 602 beds, in constant use. The school buildings, which are separated from the hospital by a quadrangle, comprise numerous theatres, laboratories, and class rooms, which are well adapted for the modern teaching of large bodies of students in all subjects of the medical curriculum. There is a large library and reading-room, and a very complete museum and gymnasium.

Appointments are open to all students. A resident assistant physician and a resident assistant surgeon are appointed annually at a salary of £100 with board and lodging; two resident casualty officers at a salary of £100 per annum. Two hospital registrars, at an annual salary of £100 each, are appointed yearly. The tenure of these offices may be renewed for a term not exceeding two years. An obstetric tutor and registrar is appointed each year at an annual salary of £50. Four house physicians, two house physicians to out-patients, four house surgeons, four house surgeons to out-patients, two obstetric house physicians, two ophthalmic house surgeons, and eight clinical assistants in the special departments are appointed every three months.

Scholarships, Prizes, &c.—Three entrance scholarships are offered for competition in September, *vis.*, one of £150 and one of £60 in chemistry, physics, and biology at the commencement of the second year; one of £50 open to University students who have passed in anatomy and physiology, for a medical degree in any of the Universities of the United Kingdom, and have not entered as students in any London Medical school. Numerous scholarships, prizes, and medals are open to competition throughout the whole career of a student, including a Fellowship of £100 given by the Salters' Company for research in pharmacology, and the Louis Jenner research scholarship, £60, for pathological research.

Special courses of instruction for the Preliminary Scientific and Intermed., M.B.Lond., for the Oxford and Cambridge examinations, and for the Primary and Final F.R.C.S. are held throughout the year.

A register of approved lodgings is kept by the medical secretary, who has a list of local medical practitioners and others who receive students into their houses. The prospectus of the school may be obtained on application to Mr. G. Q. Roberts, Secretary of the Medical School.

UNIVERSITY COLLEGE AND HOSPITAL.—The hospital with college opposite, are situated in Gower Street, not far from Euston railway terminus. The number of beds available for teaching purposes is 277.

Appointments.—Eight house physicians, six house surgeons, four senior and four junior obstetric assistants, and two ophthalmic assistants are selected annually by examination from among the senior students, without fee. The house physicians and house surgeons reside in

the hospital for a period of six months, and the senior obstetric assistants for three months, and receive their board and lodging free.

The offices of out-patient physicians' and surgeons' assistants, clinical clerks, surgeons' dressers, and ophthalmic surgeons' assistants are filled by pupils who are also students of the college, without additional fee.

Scholarships, &c.—Entrance scholarships (examination begins on September 26th, at 10 o'clock): One of the value of £120, and two of 60 guineas for proficiency in science, the subjects being those of the Preliminary Scientific Examination of the University of London, and two of 80 guineas each, the subjects being anatomy and physiology; the Atkinson-Morley surgical scholarship of £45 a year, tenable for three years; Atchison's scholarship, value £55, tenable for two years; Sharpey physiological scholarship, value about £105 a year; Filliter exhibition for proficiency in pathological anatomy, value £30; Erichsen prize, operating case, value £10 10s., awarded for practical surgery, Dr. Fellowes' clinical medals, the Liston gold medal, Alexander Bruce gold medal, Cluff memorial prize, Tuke medals for pathology, class medals, &c., gold and silver medals or other prizes, as well as certificates of honour, are awarded after competitive examinations in particular branches of study. The Tuffnell scholarship of £80 for chemistry, two years; and the Clothworkers' exhibitions in chemistry and physics of £30 each, can also be held in the medical faculty.

Composition Fees.—The following have been grouped to meet the requirements of the various examining boards: A.—For the Courses required by the University of London. 1. For the Preliminary Scientific course: 25 guineas, entitling to one attendance. 2. For the Intermediate Course: 60 guineas, if paid in one sum; 62 guineas if paid in two instalments. 3. For the Final M.B., B.S. Course: 80 guineas, if paid in one sum; 82 guineas, if paid in two instalments. This course of instruction is also suitable for the corresponding examinations at the Universities of Oxford, Cambridge, and Durham.

B.—For the Medical education required by the Examining Board in England and the Society of Apothecaries: 4. For the Course required for the First Examination: *30 guineas entitling to one attendance. 5. For the Second: 50 guineas, if paid in one sum; 51 guineas, if paid in two instalments. 6. For the Course required for the Third Examination: 80 guineas, if paid in one sum; 82 guineas, if paid in two instalments.

The composition fee in each case entitles to attendance on Lectures and Hospital Practice during three years.

C.—For Dental Students. Composition fee for the Courses required for the L.D.S., 65 guineas; or exclusive of chemistry, practical chemistry, physics, and materia medica, 50 guineas.

Students may repeat attendance at the Courses in chemistry and physics for £3 3s. (inclusive) and in elementary biology for £2 2s.

WESTMINSTER HOSPITAL.—This hospital is conveniently situated, facing the Abbey, and is readily accessible from all parts of the Metropolis. It contains 205 beds for general cases, and all the special departments. New school buildings have been erected close by which afford accommodation for 150 students. The class rooms, dissecting rooms, and lecture theatre are excellent samples of modern erections, affording ample scope for study.

Appointments.—Medical and surgical registrars, each £50 per annum; two house physicians, three house surgeons, one assistant house physician, one assistant house surgeon, and a resident obstetric assistant. These officers, except the two first named, are all boarded free of expense. Fourth year's students are appointed to be clinical assistants in the various departments.

Scholarships, &c.—(a) Winter Session—The Guthrie scholarship £60, entrance scholarship £40, entrance scholarship £30, dental scholarship £20; subjects, Latin, mathematics, experimental physics, chemistry.

and either Greek, French, or German. University scholarships, £40 and £30; subjects, anatomy and physiology. Natural science scholarship, £60, same as for Prel. Sci. of University of London. Natural science scholarship, £40, chemistry and physics. Free presentation, open to pupils of Epsom Medical College. (b) Summer Session.—Natural science scholarship, £60, same as winter. Natural science scholarship, £40, same as above. Arts scholarship, £60, arts scholarship, £40, University scholarships, £40 and £30, subjects same as in winter session. (c) Prizes, to be competed for by unqualified men. Chadwick, 20 guineas for students of any year not exceeding fifth. Bird medal and prize, £14 for students who have completed fourth winter session. Sturges prize in clinical medicine, £8, clinical surgery prize, £5. And class prizes in the various subjects.

Fees.—(a) For course required by Conjoint Board. In one payment of 110 guineas, or two payments of 60 guineas each, payable on entrance and at the commencement of second year respectively, or by six payments distributed over six sessions of 25 guineas and 20 guineas alternately. (b) For the entire course of the University of London the composition fee is 133 guineas. Fees for shorter periods or for single courses may be learned on application to the Dean. Fees for dental students, payable in one sum on entrance, 50 guineas, or in two instalments, of £27 10s.

LONDON SCHOOL OF MEDICINE FOR WOMEN (ROYAL FREE HOSPITAL).—The school is situated in Hunter Street, Brunswick Square, W.C., and the Royal Free Hospital is in Gray's Inn Road, close to the School. The school was re-built in 1893, and the laboratories are fully equipped for all the work required for the preliminary scientific and intermediate M.B. examinations of the University of London. A course of study is specially arranged for the work required by the Conjoint Colleges of Scotland and the Society of Apothecaries. Students are also prepared for the examinations of the University of Durham and other Universities. The Royal Free Hospital contains 165 beds available for clinical study; and there is a large out-patient and casualty department. In addition to the ordinary systematic lectures at the school, clinical lectures are given at the hospital in medicine, surgery, obstetrics, ophthalmology and dermatology. Students hold clerkships and dresserships in each department.

Appointments.—Two house physicians, two house surgeons and a senior and junior resident obstetric assistant are appointed yearly. There are also many non-resident appointments including the anaesthetist and assistant anaesthetists, assistant and clinical pathologists, medical and surgical registrars, curator of museum and clinical assistants.

Scholarships.—A school scholarship of £30, and a St. Dunstan's medical exhibition of £60 yearly for three years, extendible to five years, are offered annually. In addition to these there are various scholarships and prizes offered from time to time, including the Bostock scholarship of £60 a year for two years, extendible to four years; two Mackay prizes of £20 each; the Stuart Mill scholarship of £30 a year for four years; the John Brown Bursary of £20 a year; and the Mabel Webb research scholarship of £30 a year.

Fees.—The fee for the intermediate and final M.B. University of London course is £135 in one sum, or £145 in the following instalments:—first year, £45; second year, £40; third year, £40; fourth year, £20. The fee for the preliminary science classes is £25. The fee for the course for the Conjoint Colleges or Society of Apothecaries, including elementary science, is £140 in one sum, or in the following instalments:—first year, £50; second year, £40; third year, 8£40; fourth year, £20. Further particulars can be obtained from the Secretary, Miss Dowise, M.B., 8, Hunter Street, W.C.

EXTRA-ACADEMIC INSTITUTIONS IN LONDON.

THE ROYAL DENTAL HOSPITAL.—The teaching and

hospital practice at this institution (situated in Leicester Square) are recognised by the various examining bodies. The new hospital was opened in March, 1901, and is complete in every detail with modern appliances, and the school is the most thoroughly equipped of any in the United Kingdom. The clinic of the hospital is unrivalled, no less than 90,458 cases being treated in 1904. The following scholarships and prizes are open to all full term students:—Entrance scholarship, of the value of £20, awarded in October. Subjects: Chemistry and dental mechanics. Saunders scholarship, of the value of £20, awarded to the student obtaining the highest aggregate number of marks. Storer-Bennet research scholarship of the value of £51, awarded once in three years. Robert Woodhouse prize, of the value of £10, for practical dental surgery. Class prizes are awarded by the various lecturers.

Provision is made for teaching mechanical dentistry as required by the Royal College of Surgeons, the pupils being under the guidance of the staff of dental surgeons assisted by specially appointed demonstrators.

The school contains an excellent library and a well-arranged museum.

Fees.—For the two years' hospital practice and lectures as required by the Royal College of Surgeons of England, the fee is £53 3s. in one instalment, or £55 13s. in two yearly instalments. The fee for the complete curriculum, namely, three years' instruction in mechanical dentistry and two years' hospital practice and lectures, is £175 if paid in one instalment, or 175 guineas if paid in three instalments of 75 guineas in the first year, and 50 guineas each in the second and third years. For one year's instruction in mechanical dentistry the fee is 50 guineas. The necessary course of two years at a general hospital can be taken simultaneously with that at the Royal Dental Hospital. Further particulars can be obtained on application to the Dean.

NATIONAL DENTAL HOSPITAL.—This institution is centrally situated (Great Portland Street, W.), and excellent teaching facilities and hospital practice are here obtainable, special demonstrations being given by members of the staff. There are also a mechanical laboratory, bacteriological laboratory, museum, students' common room, a metallurgical laboratory, extraction and stopping rooms, lecture hall, regulations room, &c., all lighted by electricity, and warmed and ventilated after the most approved requirements; in fact, this institution may be pronounced a model dental hospital and school. The winter session commences at the same time as at the medical schools, on October 2nd. The medical tutors hold special classes before each college examination. The prizes include two entrance exhibitions, value £40 and £20, and the Rymer prize of £5 gs., the examinations for which are held in May and October. The fee for two years' hospital practice required by the curriculum, including lectures, is £40. (See advt.)

LONDON SCHOOL OF TROPICAL MEDICINE (University of London).—This Institution is the outcome of a suggestion by the Right Hon. Joseph Chamberlain, H.M. late Secretary of State for the Colonies, and is situated at the Royal Victoria Docks, in connection with the Seamen's Hospital, than which no more suitable spot could be found, as ships arrive there in great numbers from the Tropics, affording immediate opportunity for the study of tropical diseases. The school buildings are placed within the hospital grounds, and systematic courses of instruction are obtainable from duly authorised teachers throughout the year. Students also have the privilege of attending the medical and surgical practice at the "Dreadnought" Hospital, Greenwich. Information as to fees, &c., can be obtained of the Dean or the Secretary.

Medical students are admitted to the practice of the following Metropolitan hospitals to which no medical school is attached. Detailed particulars will be supplied on application to the various secretaries.

WEST LONDON HOSPITAL, Hammersmith.—This

contains 175 beds, and has an extensive out-patient department. Dresserships and clinical clerkships may be obtained. Two house surgeons and two house physicians are selected every six months. There are special departments for diseases of the throat, nose and ear, skin, women and children, and deformities. Electrical and X-ray departments have also been added. The practice of this hospital is reserved exclusively for medical men, junior students not being admitted.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway Road, N.—This institution has been greatly enlarged, contains 167 beds, cases in various special departments are treated, and the hospital is now recognised for study during the fifth year by the Conjoint Board. The practice of the hospital is open to practitioners and senior students, and clinical and pathological assistants are appointed in the wards and out-patient departments, as in the larger general hospitals.

BETHLEM ROYAL HOSPITAL.—In this Royal institution only cases of lunacy are received, and students intending to pursue this special branch have the best possible opportunities afforded here. The hospital contains 300 beds, and two resident house physicians who have recently obtained their diplomas to practise medicine and surgery are elected every six months, and are provided with apartments, complete board, attendance, washing, and an honorarium of 25 guineas per quarter. The students of certain specified London medical schools receive clinical instruction in the wards of the hospital, and qualified practitioners may attend for a period of three months on payment of a fee. Post-graduate lectures are also given.

NATIONAL HOSPITAL FOR EPILEPSY AND OTHER DISEASES OF THE NERVOUS SYSTEM, Queen's Square, W.C., contains 200 beds. It has on its staff men of European reputation, and the institution is recognised by the Conjoint Board where part of the fifth year of study may be devoted to clinical work. Clinical clerks are appointed to the physicians for out-patients, and courses of lectures and clinical demonstrations are given each year.

LONDON TEMPERANCE HOSPITAL.—The hospital contains 110 beds, and is conducted as its name implies on non-alcoholic principles by an excellent staff. The medical and surgical practice is open to students and practitioners. Appointments (vacancies for which are advertised in the medical journals): Surgical and medical registrars, resident medical officer, and one assistant resident medical officer.

METROPOLITAN HOSPITAL, Kingsland.—This was until recently known as the Metropolitan Free Hospital, is situated in the north-eastern district of the Metropolis, and contains 160 beds. It is a general hospital, with various special departments for the treatment of diseases of the eye, throat, ear, &c.

TOTTENHAM HOSPITAL, N.—This hospital contains medical and surgical wards and a ward for children, having in all 73 beds. There are special departments for gynaecological cases, diseases of the eye, ear, throat and nose, and skin diseases. It has now been authorised by the University of London to give certificates of post-graduate study for the M.D. and M.S. degrees.

HOSPITALS FOR CONSUMPTION.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—The largest institution for the treatment of affections of the chest in the United Kingdom, there being 321 beds in the two buildings. There are four house physicians who reside in the hospital, each for a period of six months. Lectures and demonstrations are given by members of the medical staff on Wednesdays and Fridays at four o'clock, save during the vacations. Terms, £2 2s. for three months; £5 5s. perpetual. This hospital is recognised by the Conjoint Board, the University of London, and the Apothecaries' Society.

MOUNT VERNON HOSPITAL, Hampstead and Northwood.—This institution, formerly called the North London Consumption Hospital, now carries on its work at Hampstead with 145 beds, and at Northwood

with 100 additional beds, where treatment is carried out on the most modern lines, including the "open air" and other systems. Students are admitted to the practice of the hospital under certain conditions, and post-graduate courses are regularly delivered during the year.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park.—This is a large and well-equipped hospital at the East End, containing 164 beds. Clinical lectures and demonstrations are given by the members of an exceptionally experienced staff. Fee for three months' attendance on hospital practice, 2 guineas; six months, 3 guineas.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road.—(80 beds.)—This hospital has been enlarged by the addition of a very complete out-patients' department, and also by the erection of a new wing, which provides accommodation for 80 in-patients.

THROAT AND EAR HOSPITALS.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn Road.—In addition to the in-patient department, which is now undergoing enlargement by the addition of more beds and an operating theatre, there is an extensive out-patient department in which clinical demonstrations are given daily during the hours of the surgeons' visits. Full facilities are afforded for acquiring sound practical experience of the subjects. Twelve clinical assistants, who must be duly qualified, are elected to assist the surgeons. Operation days—Tuesdays and Fridays, 2 p.m. Fees for the three months' attendance, £3 3s.; six months', £5 5s. Full details of this institution and post-graduate work will be found on reference to our advertising columns or on application to the Dean.

HOSPITAL FOR DISEASES OF THE THROAT, Golden Square, W.—This hospital has been recently rebuilt and contains 50 beds. Clinical instruction is given daily in the Out-patient Department on diseases of the nose, throat, and ear. There are nine clinics weekly, and an annual out-patient attendance of nearly 50,000. Major and minor operations daily (Mondays excepted) in different theatres. Four senior and forty-two junior clinical assistants are appointed from among the students to assist the surgeons. Students are admitted to the practice of the hospital at the following fees:—Three months, £5 5s.; six months, £7 7s.; perpetual attendance, £10 10s. Further details can be had by applying to the Dean.

METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL.—The hospital was founded in 1838, and is situated in Grafton Street, Tottenham Court Road. The out-patient department is open daily at 2.30 p.m. to practitioners and students for acquiring clinical instruction and technical knowledge. Operations are performed on in-patients on Tuesdays, Wednesdays, and Thursdays at 9 a.m. Fee for one month's attendance at the hospital one guinea, and for three months two guineas. During the forthcoming session demonstrations will be given by members of the staff on the pathology and treatment of diseases of the ear and respiratory passages. Short practical classes will also be held in clinical pathology and surgical anatomy. Weekly clinical lectures are given by the staff on the special disease treated at the hospital.

WOMEN AND CHILDREN.

THE HOSPITAL FOR WOMEN, Soho Square.—The hospital contains 61 beds. In connection with this institution there is now an organised school of gynaecology open to qualified medical men and to students after their third year. Clinical assistants to the physicians and surgeons in the in-patient and out-patient departments are appointed every three months. Fee for the three months' course, and certificate, £8 8s.

THE SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN, Lower Seymour Street, W., offers excellent opportunities for clinical study and training in the details of operative gynaecology. The success of the staff in this department has gained for them a European reputation. There are 47 beds

ROYAL WATERLOO HOSPITAL FOR CHILDREN AND

WOMEN.—This important institution, situate in South London, has been in a transition state for some time past, having been partly rebuilt and appointed on ambitious lines, and when completed, which it is expected to be shortly, will contain 200 beds.

HOSPITAL FOR SICK CHILDREN in Great Ormond Street, Bloomsbury, W.C., and Cromwell House, Highgate.—Fee for three months' attendance, £2 2s.; perpetual, £3 3s. There are now 200 beds, besides 52 additional at the convalescent branch, and it is probably the largest institution of the kind in the world. The practice of the hospital is open to pupils of the different hospitals and medical schools of London and medical practitioners on conditions to be ascertained from the Secretary.

EYE HOSPITALS.

ROYAL LONDON OPHTHALMIC HOSPITAL, formerly in Moorfields, and recently rebuilt in the City Road, is the largest hospital devoted to this specialty in Great Britain, and contains 138 beds. Students and practitioners are admitted to the practice daily at 9 o'clock. Operations, 10 o'clock and after. Fee for six months, £3 3s.; perpetual, £5 5s. Further particulars of the Secretary.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, adjoins Charing Cross Hospital in King William Street. It has about 40 beds and a very large out-patient *clinique*. The lectures and demonstrations are arranged with special reference to the requirements of practitioners and senior students. Fee, six months, £3 3s.; perpetual, £5 5s.

ROYAL EYE HOSPITAL, St. George's Circus, Southwark.—There are 40 beds and two cots. Fees, £2 2s. for three months, £3 3s. for six months, and £5 5s. perpetual. Courses are held on ophthalmoscopy, refraction, and diseases of the eye; fee, £1 1s. for each course, but perpetual students may attend each course once without extra fee. Pathology class, £1 1s. extra to cover cost of materials.

SKIN HOSPITALS.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.—Out-patient department, Leicester Square; In-patient department, Uxbridge Road, W. This hospital has a well-equipped in-patient department, with 50 beds. It has a School of Dermatology at 49 Leicester Square, which is conducted by the medical staff of the hospital. During the past year the free course of Chesterfield Lectures given by Dr. Morgan Dockrell has proved a great success, being well attended by the profession. The next course (free) will commence on Thursday, October 5th, at 6 p.m., in the Lecture Room of the Hospital, Leicester Square. The Out-patient Department has just been rebuilt at a cost of £10,000, and contains a spacious laboratory and lecture and special department for X-rays, high frequency, and Finsen treatment. (See Advt.)

One of the oldest institutions of the kind is the Western Skin Hospital (Great Portland Street), which was started as long ago as 1851. The practice of the hospital is open to students and practitioners. Students of this specialty have also the London Skin Hospital, in Fitzroy Square, with seven beds and an out-patient department of over 1,400. There is also the Stamford Street Skin Hospital, in the southern part of the Metropolis, with 10 beds and an out-patient department of 5,600, so that the students' needs in this direction are well catered for.

METROPOLITAN POST-GRADUATE INSTITUTIONS.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.—This institution affords to medical men special facilities for acquiring technical skill, and advancing their medical and scientific knowledge. The building, which is large and commodious, is situated in Chenies Street, Gower Street, and contains lecture and consulting rooms, pathological and clinical laboratories, Röntgen ray room, an ophthalmoscope room, a library and museum, and reading and smoking rooms. *Cliniques*, at which patients are shown, are given every day of the week except Saturday, at 4 p.m. Lectures on Medicine,

Surgery, and other allied subjects are delivered on Mondays, Tuesdays, Wednesdays, and Thursdays at 5.15 p.m. Four sessions of practical classes, each lasting six weeks, and a vacation session of three weeks' duration, are held during the year, the subjects taught comprising ophthalmology, otology, clinical microscopy, laryngology, urinary analysis, gynaecology, applied anatomy, nervous diseases, and practical X-ray work. There are, in addition, extra-mural classes in operative surgery, bacteriology, and public health.

A complimentary ticket for three days, admitting to *cliniques* and lectures, is issued to any medical practitioner on personal application at the college. The annual subscription for medical practitioners of either sex, holding qualifications granted in any of H.M.'s dominions—wherever resident—is One Guinea. Full information may be obtained from the medical superintendent, Mr. Hayward Pinch, F.R.C.S.

WEST LONDON POST-GRADUATE COLLEGE.—The West London Hospital, Hammersmith Road, W., contains 159 beds; the post-graduate course was started in 1895, and this is the only post-graduate college in London attached to a general hospital. Instruction is given in the out-patient department daily at 2.15 p.m. by the assistant physicians and assistant surgeons. The physicians and surgeons attend daily at 2.30 p.m., when post-graduates can accompany them in their visits to the wards. Operations are performed daily at 2.30 p.m. There are lectures every evening at 5 p.m. (Saturdays excepted).

Fees.—The fee for the hospital practice including all the ordinary lectures and demonstrations, is £1 1s. for one week; £2 2s. for one month; £5 5s. for three months; £8 8s. for six months; £12 12s. for one year, and £25 for a life ticket. A course of attendance on either the medical or surgical practice alone may be taken out for the fee of £3 3s. for three months. The fee for three months' attendance in any one special department, other than medicine or surgery is £2 2s. A prospectus containing full particulars will be forwarded on application to Mr. L. A. Bidwell, Dean.

NORTH-EAST LONDON POST-GRADUATE COLLEGE.—This post-graduate school is established in connection with the Tottenham Hospital, N., which is recognised by the University of London as a place of post-graduate study for the M.D. and M.S. degrees. Facilities are here afforded to qualified medical practitioners for taking part in the work of an active general hospital, and for attending demonstrations of various branches of medicine, surgery and gynaecology, with opportunities for clinical instruction in diseases of the eye, ear, throat, nose, skin, in fevers, psychological medicine, the administration of anaesthetics, and dentistry. *Cliniques*, lectures and demonstrations are given by members of the teaching staff in the lecture room, in the wards, in the various out-patient departments, and in certain affiliated institutions. Operations are performed every afternoon of the week, except Saturday. Special classes, the attendance at which will be limited, are arranged in gynaecology, the surgical diseases of children, including orthopaedic surgery, diseases of the throat, nose and ear, diagnosis of diseases of the nervous system, ophthalmoscopy and refraction, analysis of the gastric contents, clinical examination of the blood, diseases of the skin, abdominal surgery, radiography, bacteriology, and medical electricity. The fee for a three months' course of study, which may be begun at any time, in any single department, is one guinea. A fee of three guineas admits to the whole practice of the hospital for a similar term (one month, 2 guineas), and a perpetual ticket for the practice of the hospital may, for the present, be obtained on payment of a fee of 5 guineas. Additional information with a syllabus of lectures demonstrations, and special classes, may be obtained from the Dean of the Post-Graduate College, Dr. A. J. Whiting, 142, Harley Street, W.

PROVINCIAL MEDICAL SCHOOLS.

BRISTOL UNIVERSITY COLLEGE.—FACULTY OF MEDICINE.—The lectures and instruction given in the

Faculty of Arts and Science of University College, Bristol, are adapted to the various preliminary examinations, and students can complete in Bristol the entire course of study required for the medical and surgical degrees of the University of London and the Royal College of Surgeons of England, and of the Apothecaries' Society of London, and for the examination of the Army and Navy Boards. Students of the college are admitted to the clinical practice of those very important and well-equipped institutions, the Bristol Royal Infirmary and the Bristol General Hospital. The infirmary and the hospital comprise between them a total of 470 beds, and both have very extensive outpatient departments, and special departments for the diseases of women and children, and of the eye, ear, and throat, besides large outdoor maternity departments and dental departments. Students of the college also have the privilege of attending the practice of the Bristol Royal Hospital for Sick Children and Women, containing 104 beds, and that of the Bristol Eye Hospital, with 40 beds. The total number of beds available for clinical instruction is therefore 614. Very exceptional facilities are thus offered to students for obtaining a wide and thorough acquaintance with all branches of medical and surgical work.

Appointments.—At the Royal Infirmary, and also at the General Hospital, clinical clerks and dressers reside in the house in weekly rotation. A pathological clerk is appointed every three months. Also obstetric clerks and ophthalmic dressers. Clinical lectures are given regularly at both institutions.

Scholarships, Prizes, &c.—Prizes and certificates of honour are given in University College in all the subjects of the curriculum. There are two entrance scholarships, value £50 and £30 respectively, two Martyrs memorial scholarships (pathology and morbid anatomy) of £10 each, the Tibbits memorial prize, value £9, for proficiency in practical surgery, Henry Marshal prize, £12; Clarke Scholarship, £15; Sanders Scholarship, £22 10s.; one gold and silver medal awarded by the committee, and various prizes for clinical work in surgery and medicine.

Fees.—School fees for attendance on all courses of lectures, except comparative anatomy, 70 guineas, or 55 guineas. Dental composition fee, 60 guineas. Clinical fees—Surgical practice, one year, 12 guineas; perpetual, 20 guineas. Medical practice, 20 guineas; perpetual medicine and surgery, 35 guineas; clerk or dresser, 5 guineas; obstetric clerk, 3 guineas.

Prospectus and further information on application to the Dean, Professor E. Markham Skerritt.

SHEFFIELD UNIVERSITY COLLEGE.—*Faculty of Medicine.*—The Winter Session, 1905-6 will commence in the new University building on Monday, October 2nd.

The University was opened on July 12th by the King. The plan of the buildings is that of four blocks, enclosing a quadrangle, 154 ft. by 110 ft. The medical department occupies the entire north wing overlooking the quadrangle on one side and Weston Park on the other. The anatomical department occupies about two-thirds of the upper ground floor. The dissecting room has been designed and equipped to meet all modern requirements of the student of anatomy. The lecture theatre will accommodate fifty students, and is provided with a lantern of modern type illuminated by the electric arc. The anatomical museum has a gallery which is set apart chiefly for anthropological and morphological collections. The floor space affords accommodation for bones, models, and spirit specimens mounted in glass jars. Research laboratories and private rooms are provided for the professors and demonstrators. The department of physiology occupies the first floor. In the general laboratory, a large and well lit room, accommodation is provided for microscopical work at a bench running the full length of the laboratory beneath the windows; the space behind is occupied by movable tables each equipped for the purposes of experimental work, an arrangement which enables the students to work either singly or in small groups. The fixed equipment of the room is designed to provide power for machinery, gas,

electricity, and water wherever the tables may be situated. The second laboratory for chemical physiology is fitted with benches, fume cupboards, &c. In addition a considerable portion of the space in this room is devoted to and equipped for work of a more advanced type. Opening into this laboratory are a balance room and two rooms fitted for photography, spectroscopy, &c. Opportunities are afforded for research work in three special rooms. One, beautifully lighted by windows in two of its walls, is equipped for general research, another a room which can be darkened for optical work and photographic recording; and a third in the basement is provided with the solid pillars, &c., necessary for work with delicate instruments requiring great stability. In the lecture theatre, seating fifty students, a large amount of space has been left for the demonstration of experiments, and is equipped with the larger pieces of apparatus necessary for such work. The whole upper storey of the medical block is occupied by the Department of Pathology. The students' laboratory, a very large and lofty room, is fitted and equipped with every modern appliance for microscopical and bacteriological work. The lecture theatre has sitting accommodation for about fifty students. The incubating room, built into the centre of the pathological department, is a special feature; it is so arranged that it may be kept at a constant temperature, thus replacing the ordinary incubating ovens. The museum is spacious and is furnished with a gallery. Research laboratories are provided for the professor. On the upper ground floor are well-furnished lecture rooms for other subjects, and the *materia medica* museum. The library of the Sheffield Medico-Chirurgical Society, to which students are admitted, is situated on the ground floor overlooking the quadrangle.

Hospital practice is taken out at the Royal Infirmary (247 beds) and at the Royal Hospital (160 beds), both of which institutions have special departments for diseases of the eye, ear, and throat, and skin. At the latter there is also an extensive dental department. Perpetual fee, £45; or in two payments, viz., £26 on entrance, £22 within twelve months afterwards. Students are also admitted to the practice of the Jessop Hospital for diseases of women (80 beds), the City Fever Hospitals, and the South Yorkshire Asylum. The dental department is recognised by the examining bodies. The courses of instruction for the D.P.H. are recognised by the University of Cambridge, London University, and the Royal College of Surgeons.

Students of either sex are admitted to the degrees of the University.

The Kaye scholarship, for second year's students, natives of Sheffield, is awarded annually, under certain regulations. Prizes for clinical medicine and clinical surgery; prizes in books and certificates awarded annually.

UNIVERSITY OF WALES, CARDIFF SCHOOL OF MEDICINE.—This college, which is one of the colleges of the University of Wales, has since its foundation, in 1883, prepared students for the Preliminary Scientific examination of the University of London, and for the corresponding examinations of other licensing bodies. In 1893 Chairs of Anatomy and Physiology and a Lectureship in *Materia Medica* and Pharmacy were established, making it possible for students of medicine to spend three out of the five years of prescribed study at Cardiff. Arrangements with the managing committee of the Cardiff Infirmary give students of the College the privilege of attending this large and well-ordered hospital, which is situated within five minutes' walk of University College. Many students, especially from Wales and Monmouthshire, avail themselves of the opportunities thus afforded to pursue the earlier part of the medical curriculum near home. All classes are open alike to both men and women students over sixteen years of age. The courses of instruction given at Cardiff are recognised as qualifying for the examinations of the Universities, Royal colleges, and other licensing bodies of Great Britain and Ireland. Having spent two or three years in study at Cardiff, and having

passed the examinations in these years, a student may proceed to London or elsewhere and complete his qualifying course for a University degree or for a college diploma.

Students preparing for the first and second examinations of the Conjoint Board for England, or for the corresponding examinations of the Conjoint Board for Scotland, or for those of the Society of Apothecaries, may compound for their classes by paying a single composition fee of £41 10s., or by paying £20 and £24 10s. at the beginning of their first and second years respectively. Those preparing for the preliminary scientific and intermediate examination in medicine of the University of London may compound for their three years' instruction at Cardiff by paying a single composition fee of £57 10s., or by paying £13 13s., £28, and £21 at the beginning of their first, second and third years respectively.

In 1899 a department of Public Health was established, and lecturers in bacteriology and in public health and hygiene were appointed. Medical men preparing for a diploma in Public Health and Hygiene can attend complete courses of lectures and laboratory instruction in this department. These courses are recognised by the University of Cambridge, by the Royal Colleges of Physicians and Surgeons, and by Victoria University.

In the case of medical students, attendance on the class of hygiene and public health is accepted by the Universities of London and Cambridge, and by the Conjoint Examining Board of England.

Courses of lectures to midwives, adapted to the requirements of the Central Midwives' Board, under the Midwives Act, are commenced in October, January, and April. The lectures are suitable both for pupil midwives and practising midwives, as well as for nurses who desire to enter for the examination for certification under the Act.

Scholarships, &c.—The attention of students about to matriculate is drawn to the numerous entrance scholarships for exhibitions which are offered at the college for competition in September, most of which may be held by medical students. Full particulars of the examination for these may be obtained from the Registrar, or from the Dean of the Medical Faculty.

LIVERPOOL ROYAL SOUTHERN HOSPITAL.—The clinical school of this hospital is situated within convenient distance of the Liverpool University, and affords every facility for clinical and pathological study. The hospital contains 200 beds, and in addition to the general medical and surgical cases attention is devoted to the diseases of women and children. There is a special ward for tropical diseases in connection with the University laboratories.

The medical and surgical staff visit the wards daily, and the ward instruction is supplemented by weekly clinical lectures. Additions have been made to the teaching staff so that students may now obtain instruction in diseases of the eye, ear and throat. Demonstrations in the use of the X-ray apparatus are given at intervals. There is an excellent pathological department, with laboratory attached, where demonstrations are arranged for and regular instruction is given in practical pathology. The practice of St. George's Hospital for Diseases of the Skin is free to students, and thus ample opportunity is afforded for acquiring a knowledge of dermatology. In addition to the clinical clerkships which are allotted to the students the resident posts of ambulance officers are given to the students whom the board may think most suited to hold them every three months. The Alexander Fellowship in Pathology of £100 a year is open to students of this school; three prizes of £5 each are also awarded to the gentlemen who present the best taken series of medical and surgical cases. *Fees:* Perpetual, £26 5s.; one year, £10 10s.; six months, £7 7s.; three months, £4 4s.

There are rooms for a limited number of resident students; terms (exclusive of fee for hospital practice), £15 15s. per quarter. The practice of the hospital is recognised by all examining bodies.

LEEDS UNIVERSITY.—This school of medicine was

originally founded more than seventy years ago as the Leeds Medical School. The building, erected on a site contiguous to the infirmary, and opened eleven years since, contains one of the finest dissecting rooms in the Kingdom, extensive laboratories for physiology and pathology with the most recent improvements in fittings and apparatus, ample lecture-room accommodation, a large library, and separate museums for pathology and anatomy. Professors and lecturers are attached, and the clinical teaching is given by the physicians and surgeons attached to the Leeds General Infirmary, one of the largest in the United Kingdom, having 432 beds, with a staff of physicians and surgeons of considerable eminence. Ophthalmic demonstrations and demonstrations of skin diseases are given in the infirmary by surgeons in each department, where also are obtainable various clinical clerkships, dresserships, and other appointments; and an extern maternity charity is attached, at which the necessary attendance at labours can be taken. Besides the infirmary there is a large dispensary, a large hospital for infectious diseases, and a hospital for women and children, all of which are open to students of the school.

Scholarships, Prizes, &c.—(1) A Gilchrist scholarship of £50 a year for three years is awarded annually. (2) A University scholarship of £25 (awarded annually). (3) An entrance scholarship of 64 guineas. There is also a Hardwick prize in clinical medicine, a M'Gill prize in clinical surgery, each of the value of £10, and Thorpe prizes of £10 and £5 in forensic medicine and hygiene, and a Scattergood prize in midwifery, besides silver and gold medals and other class prizes. The composition fee for attendance upon all the required courses of school lectures is 64 guineas for University students who have attended the preliminary scientific courses, and the same for non-University students, exclusive of chemistry and biology.

At the General Infirmary, the perpetual fee for medical and surgical practice and clinical lectures is £42 in one sum, or two instalments of £22 each. These fees are not included in the composition fees for lectures and are payable separately.

At the General Infirmary, the perpetual fee for medical and surgical practice and clinical lectures is £42 in one sum, or two instalments of £22 each. These fees are not included in the composition fees for lectures, and are payable separately.

A scholarship of £42 to cover the cost of medical and surgical practice is offered annually by the Infirmary.

LIVERPOOL SCHOOL OF TROPICAL MEDICINE.—This school, which has for its object research into Tropical Diseases and Improvement in Tropical Sanitation, was founded in Liverpool in 1899 by Sir Alfred Jones, K.C.M.G., who is the chairman of the school. The research work of the school is carried on at the Johnston Laboratories, in Liverpool University. The clinical work is carried on at the Royal Southern Hospital. A special feature of the work of the Liverpool School of Tropical Medicine has been the despatch of a large number of important medical expeditions to various places in the tropics, especially West Africa. Although the School has only been in existence for a short time it has already sent over a dozen of these expeditions. In addition, the School has issued a number of valuable publications and monographs on subjects connected with tropical diseases. The Duke of Northumberland, K.G., is Hon. Vice-President; Sir Alfred L. Jones, K.C.M.G., Chairman of Council; and Mr. Wm. Adamson, Vice-Chairman; and the following is the school staff: Sir Alfred Jones Professor, Ronald Ross, C.B., F.R.S., F.R.C.S.; Walter Myers Lecturer, J. W. W. Stephens, M.B. Cantab; Lecturer in Economic Entomology and Parasitology, R. Newstead, F.S.A. Lecturer in Tropical Diseases of Animals, H. E. Annett, M.D.; Walter Myers Fellow, J. Everett Dutton, M.B., Ch.B.; Assistant Lecturer, C. Christy, M.D.; Demonstrators and Research Assistants, J. L. Todd, B.A., M.D., C.M. McGill, and H. Wolferston Thomas, M.D., C.M. McGill; Dean, Professor Rubert

Boyce, M.B., F.R.S.; Hon. Secretary, A. H. Milne, B.A.

The following are the principal provincial hospitals having the greatest number of beds, to which students are admitted where clinical instruction can be obtained, but to which there is no medical school attached :—

BATH ROYAL UNITED HOSPITAL.—This is a well-appointed hospital in the West of England, with 130 beds, at which students can obtain clinical instruction. The hospital is recognised by the Colleges, and is licensed for dissection. It contains also an excellent museum and library. Fee for six months' attendance, five guineas; twelve months', ten guineas.

BRADFORD INFIRMARY.—The hospital contains 220 beds. Non-resident pupils are received and abundance of clinical material is obtainable. One year's attendance is recognised by the Examining Boards. Fee, perpetual, £10 10s.

BRIGHTON SUSSEX COUNTY HOSPITAL contains 190 beds. It is recognised by the College of Surgeons and by the Conjoint Board. Out-pupils are admitted to the clinical teaching and the classes at a fee of £21 for two years.

LIVERPOOL NORTHERN HOSPITAL, which has recently been rebuilt, now contains 246 beds, and is completely equipped with the most modern appliances. Clinical instruction is given by the staff during the summer and winter sessions. Clinical clerkships and dresserships are open to all students without additional fees. Fees for hospital attendance: Perpetual, £26 5s.; one year, £10 10s.; six months, £6 6s.; three months, £4 4s.; practical pharmacy, £2 2s.

NORFOLK AND NORWICH HOSPITAL.—This hospital is recognised by the Colleges, and contains 220 beds. Fees, £10 10s. for six months, £15 15s. for twelve months' medical and surgical practice. Pupils, resident and non-resident, are admitted.

NORTHAMPTON GENERAL INFIRMARY.—The number of beds is 163. Out-pupils are received, and have every opportunity of acquiring a practical knowledge of their profession. Instruction is also given in anatomy and materia medica and practical pharmacy. Non-resident pupils are taken at a fee of £10 10s.

ROYAL BERKSHIRE HOSPITAL.—The town of Reading, in which this hospital is situated, has a very large working-class population, and excellent opportunities for clinical instruction in the wards and extensive out-patient department are afforded here. It contains 160 beds, a splendid library, in which the Reading Pathological Society holds its meetings.

THE ROYAL HOSPITAL, Portsmouth.—The hospital is a preparatory school of medicine and surgery, and the attendance of pupils is recognised by the Examining Boards. The number of beds is 120. The fees are the same as at all similar institutions,

ROYAL DEVON AND EXETER HOSPITAL, Exeter.—The hospital contains 200 beds (including special children's wards), and has a good library, museum, dissecting room, and post-mortem room. Attendance on the practice of this hospital qualifies for all the Examining Boards. Arrangements can be made by which students can attend midwifery on application to the House Surgeon.

NORTHAMPTON GENERAL HOSPITAL.—This hospital contains 174 beds; it has been recently enlarged and re-arranged. Non-resident pupils are received and have every opportunity of acquiring a practical knowledge of their profession. The fee is £10 10s.

WOLVERHAMPTON GENERAL HOSPITAL.—The hospital contains 230 beds, attendance at this hospital being recognised by all the Examining Boards. Pupils are trained in clinical work by the medical and surgical staff. Fees: Six months, £6 6s.; twelve months, £12 12s.; perpetual, £21.

Ireland.

THE IRISH MEDICAL SYSTEM.

The system of medical teaching in Ireland differs from that in England in important particulars. In London each clinical hospital has its attached medical school, which is fully equipped, and which educates the students of that hospital and very seldom those of any other. In Dublin, on the contrary, the hospitals and schools are entirely separate (except that Sir Patrick Dun's Hospital is officially connected with Trinity College), and a student of any hospital is free to enter for the whole or any part of his course at any school or hospital he pleases. As might be expected, religion, social rank, and locality of residence have their influence in causing certain classes of students to resort to schools and hospitals suitable to their condition. But scholastic or collegiate regulations impose no restrictions as to the place of study, and as the school and hospital fees are paid in detail in Dublin, and not in a lump sum, as in London, the pupil is free to do as he pleases.

BOARD AND RESIDENCE.

There is in Dublin no organisation for domestic accommodation of medical students, save for those who are passing through Trinity College, in whose case rooms and "commons" (*i.e.*, dinner) are provided at fixed rates. Those who can afford to pay £6 6s. or £7 7s. per month for their lodging and maintenance may find accommodation in the family of some medical man who receives boarders, in which case they become members of the family for the time being. The majority of Dublin students, however, take a lodging in some economical locality, or they "chum" with some other student for the purpose. It is usual to contract with the lodging-house keeper for board or partial board, but some students cater for themselves.

COST OF MEDICAL EDUCATION IN IRELAND.

The cost of obtaining a medical qualification depends to some extent on the qualification sought. In this connection the following tables may be of use to the prospective student :—

COST OF MEDICAL EDUCATION.

School of Physic, Dub. Univ. . .	£122 6s. 6d.
Royal College of Surgeons School	£124 19s.
Catholic University School . .	£124 19s.
Queen's College	About £110

COST OF DIPLOMAS OR DEGREES.

Dublin University	£27 (to this must be added £83 4s., the cost of obtaining an Arts degree).
Royal University	£15.
Conjoint Royal Colleges	£42.
Apothecaries' Hall	£22 1s.

Thus, the absolute payment will amount to somewhere between £125 and £232 10s. 6d. according as the teaching of the Queen's Colleges and the degrees of the Royal University, or the teaching and degrees of Dublin University, are taken. For the Conjoint Colleges the entire cost is £166 19s., taking the minimum mode of payment. So that, assuming that extras or voluntary costs are incurred the total will vary, say, from £170 to £200. "Grinding" although not officially recognised, occupies a position almost identical with that of the extra-mural instruction in other schools. Its cost must be reckoned among the expenses of the course, for, while not essential, it has become customary for almost all students to obtain aid in their studies in this way. As a rule, this private instruction costs about £5 5s. for each of the four examinations.

The above sum, or something like it, may be expended by the student or his parent in paying for lectures, &c., and examination fees as they fall due, and there is no difficulty in obtaining the useful information for his guidance if he likes to pay for his course in this fashion. If, on the other hand, he prefers to pay a large sum down, he can "apprentice" himself to a teacher who will undertake all monetary responsibility for his education. This so-called "apprenticeship," is very gener-

ally a simple contract for the payment of fees, and involves but little special teaching. The practice has now become almost obsolete. All the Dublin schools require fees to be paid in advance.

DATE OF ENTRY.

The entry of names and commencement of study in Ireland is supposed to date from the 1st of October in each year, but the session really dates from the 1st of November, and the entry of names may be delayed by the dilatory to the 25th of the same month. It should, however, be remembered that no credit is given for studies or attendance until the entry is regularly made. The student must attend three-fourths of the lectures delivered, and if he loses a fortnight at the beginning he must make up for it afterwards by constant attendance.

The student begins work by attending a recognised medical school each morning at ten o'clock, and occupying his day, to five p.m., between lectures and dissections. His vacations are a fortnight at Christmas and a week at Easter, and he finally returns home at the end of June.

PRELIMINARY EXAMINATIONS.

The first act of the student is to pass a preliminary examination, without which he cannot get credit for any medical studies pursued. The next is to commence medical study. This he does by entering for lectures at a medical school. From the school registrar he gets a form of certificate, and his third act is to take it or send it to the Branch Medical Council, 35 Dawson Street, Dublin, unless, as is usually the case, this duty is undertaken for him by the school registrar. He is thereupon placed upon the Register of Medical Students (without fee), and his period of study counts from that date. He must register at the earliest possible moment, or he may lose credit for his work.

The only preliminary examination held specially for medical students is that held conjointly by the Royal Colleges of Physicians and Surgeons, but other examinations, e.g., the public entrance at Trinity College, the matriculation of the Royal University, the Intermediate Examination passes in the required subjects, and all other examinations recognised by the General Medical Council are accepted as equivalent.

The subjects of examination as prescribed by the General Medical Council are as follows:—1. English language, including a specified author, dictation, grammar, and composition; also parsing and analysis from a book specified. 2. Latin, including grammar, translation from specified authors, and translation of easy passages not taken from such authors. 3. Elements of mathematics, comprising (a) arithmetic, including vulgar and decimal fractions; (b) algebra, including simple equations; (c) geometry, Euclid, Books I., II., and III., with easy deductions. 4. One of the following optional subjects:—(a) Greek, (b) French, (c) German.

THE IRISH LICENSING BODIES.

The Medical Licensing Bodies of Ireland are four in number, and, as a rule, students gravitate into one or other of five classes:—*a.* Those who enter Trinity College, and take a full graduation in Arts in addition to their professional degrees. *b.* Those who take the licence of the conjoint Royal Colleges of Physicians and Surgeons. *c.* Those who take their qualifications at the Royal University of Ireland, where graduation in Arts is not necessary. *d.* Those who take the licence of the Apothecaries' Hall. *e.* Those who pursue their studies in Ireland, but who migrate to London, Edinburgh, or Glasgow for their licences. Almost all these last-named emigrants come from the Queen's Colleges, and the greater number of them from Belfast, while the Dublin students qualify, as a rule, in Dublin.

We do not attempt to give details as to the requisite courses of instruction for degrees or diplomata, as our epitome must necessarily be insufficient for the information of the student, and we can occupy our available space with information more useful to him. The official information upon which students may depend

can be obtained by sending a note to the Registrars of the Licensing Bodies or Schools.

The Irish Licensing Bodies are as follows:—

THE UNIVERSITY OF DUBLIN.

The University of Dublin grants the degrees of M.B., B.Ch., and B.A.O. to students who have obtained their Arts degree, and who have been for at least five academic years on the books of the Medical School, and the higher degrees of M.D., M.Ch., and M.A.O. to those who have held, or have been qualified to hold, for at least three years, the grade of M.B. and B.Ch. It does not grant degrees to any but full graduates in Arts, consequently its degrees hold the highest rank of social and educational qualifications, and are sought for by those who look forward to occupying the best positions in the profession.

The expense of obtaining the degrees of M.B., B.Ch., and B.A.O. is approximately as follows:—Lectures, £66 13s. 6d.; Hospitals, £55 13s.; Degree Fees, £27.—Total, £149 6s. 6d.

The expense of the B.A. degree, amounting altogether to £83 4s., should be added, making the total cost £232 10s. 6d.

Important new regulations come into force in the Summer Session of 1906. One of the main results of these will be to diminish the extent of the Arts course for medical students, while at the same time preserving the advantage of an Arts education by rendering the attendance on certain lectures compulsory. Changes in the medical examinations will also take place, but the curriculum itself is practically unaltered.

In addition to its ordinary qualifications the University grants the following higher degrees:—

Doctor of Medicine.—To obtain this the candidate must have obtained the degree of M.B., or have been qualified to have obtained it for three years. He must then read a thesis before the Regius Professor of Medicine. Fee for this degree, £13.

Master of Surgery.—The candidate must be a Bachelor in Surgery of three years' standing, and must then pass an examination in clinical surgery, operative surgery, surgical pathology, surgery, and surgical anatomy (on the dead subject). Fee for this degree, £11.

Master in Obstetric Science.—The candidate must have passed the M.B. and B.Ch. examinations, and have completed, in addition to the courses for M.B., B.Ch., a course of obstetric medicine and surgery. He is then required to pass an examination in the following subjects:—Practice of midwifery, gynaecology, anatomy of female pelvis and elementary embryology, and clinical gynaecology. Fee for this degree, £5.

Diplomate in Medicine, Surgery, and Midwifery.—Candidates for the diplomas in Medicine, Surgery, or Obstetric Science must be matriculated in Medicine, and must have completed two years in Arts and five years in medical studies. The course and examination is the same as for the degrees, except that the lectures and examinations in botany and zoology need not have been taken out or passed, and that the candidate need not have obtained an Arts degree. Fee for the diplomas in medicine, surgery, and midwifery, £21. A diplomate, on completing his course in Arts and proceeding to the degree of B.A., may become a Bachelor by attending the lectures on botany and zoology, passing the previous medical examination in those subjects, and paying the degree fees.

Diploma in Public Health.—The candidate must be an M.D. or a Graduate in Medicine and Surgery of Dublin, Oxford, or Cambridge, must have completed, subsequent to registration, six months' practical instruction in a laboratory, and also have studied practically outdoor sanitary work for six months under an approved Officer of Health (*v.* also page 276).

Degree and Licence in Dental Science.—Candidates for the degree in dental science must have taken a degree in Arts, and must have had their names in the books of the Medical School for five years. Two examinations must be passed—namely, the Previous Dental at the end of the second year, and the Final Dental at the end of the fifth year. Candidates for the Licence are required to matriculate in Arts, but need

not proceed further in the Arts course. The course of study is the same as for the degree with the exception that no lectures in pathology or bacteriology are required. The total fees for the licence, including the premium for Dental Mechanics (£100), are £200 17s., while those for the degree are about £210, to which must be added the cost of the B.A. degree.

Post-Graduate Classes.—A short post-graduate course is now given annually in July in connection with Trinity College Medical School. It includes special work on Diseases of the Eye, Nose, and Throat, Gynaecology, Diseases of the Skin, X-ray work, Medicine, Surgery (clinical and operative), and Clinical Pathology.

Royal Services School.—The object of this school is to prepare candidates for the Indian Medical Service, and Royal Army Medical Service. It is conducted on a comprehensive scale, and affords special opportunities for operating on the cadaver, and for the study of commentaries. Two sessions are held yearly, each lasting for about ten weeks.

THE ROYAL UNIVERSITY OF IRELAND.

The Royal University of Ireland is purely an examining body. Its degrees are granted on one year's acts, *i.e.*, the matriculation examination of this University (none other will suffice) and a "first University examination" at the termination of the first year. The cost of the M.B. and M.Ch. of the University, with all the necessary curriculum, is about £125. Some of the Arts examinations are conducted, not only in Dublin, but at certain local centres.

The University confers the following medical degrees:—

M.B., B.Ch., B.A.O., and the higher degrees of M.D., M.Ch., and M.A.O. It also confers a Diploma in Public Health and a Diploma in Mental Diseases.

All degrees are open to persons of either sex.

The University examinations are held in the spring, beginning about May 1st, and in the autumn, beginning about October 1st.

All candidates for any degree must pass the matriculation examination and the first University examination.

The course for the degree of M.B., B.Ch., B.A.O., extends over five years.

Students will be admitted to the first University examination after one year from matriculation. Fee, £1.

The medical course consists of three previous examinations, one at the end of each year, and one degree examination at the end of the fifth year. Fee for each previous examination, £1; for the degree examination, £2; for the diploma, £10.

In addition, the following degrees are granted:—

Diploma in Public Health.—Conferred only on graduates in medicine of the University of at least twelve months' standing. Fee, £2. Subjects.—Meteorology, bacteriology, chemistry, physics, vital statistics, hygiene, sanitary engineering, architecture and law.

The M.D. Degree.—Conferred only on graduates in medicine of the University of three years' standing. They must at the same time produce a certificate of having been, for at least two academical years, engaged in hospital or private, medical, surgical, or obstetrical practice, or in the military or naval medical service. The examination comprises medical diseases and the theory and practice of medicine, including pathology. Every candidate will be examined at the bedside, and be required to diagnose at least three medical cases, and prescribe treatment, and to write detailed reports on at least two cases to be selected by the examiners and to discuss the questions arising therefrom. Fee, £5.

The M.Ch. Degree.—Conferred only on graduates in medicine of the University of three years' standing, and who can produce a similar certificate of practice to that required for the M.D. degree. The examination comprises surgery, both theoretical and operative; surgical anatomy; ophthalmology and otology. Fee, £5.

The M. A. O. Degree.—Conferred only on graduates in medicine of the University of three years' standing, and who can produce a similar certificate of practice to that required for the M.D. and M.Ch. degrees. The examination comprises midwifery and diseases of women and children. Fee, £5.

Prizes, &c.—First Examination in Medicine. Two first-class exhibitions of £20 each, and two second of £10 each.

Second Examination in Medicine.—Two first-class exhibitions of £25, and two second-class of £15, and the Dr Henry Hutchinson Stewart Medical Scholarships, value £10 a year for three years. The latter are awarded in psychological medicine, diseases of the nervous system, and anatomy, physiology and pathology of brain, cord, and nerves. Competition among medical graduates of not more than three years' standing. Fee £2. Value £50 a year for three years.

Third Examination in Medicine.—Two first-class exhibitions of £30 each, and two second of £20 each.

Medical Degrees Examination.—Two first-class exhibitions of £40 each, and two second of £25 each. One travelling medical scholarship of £100. One medical studentship of £200 per annum, tenable for two years.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.

These examinations are held conjointly by the two Colleges. The course, as in other bodies, extends over five years, with examinations at the end of the first, second, third, and final years. These examinations are conducted by examiners chosen by each of the Colleges for the subjects appropriate to them. The curriculum has recently been revised, and made of a more practical nature. In common with the English Colleges, the subjects of the First Professional examination may be studied either at a medical school or at an institution other than a medical school recognised by the Colleges, after due inspection, for instruction in these subjects. We recommend students to apply for the official programme to the Secretary of the Committee of Management, Royal College of Physicians, or to the Registrar of either College. In the case of the Preliminary Examination seven clear days' notice must be given to the Secretary; fourteen days' notice is required from candidates for the Professional examination.

The total of the examination fees, spread over the four examinations, is £42, while the school and hospital fees, if taken in Dublin, amount to £124 19s., making altogether £166 19s., exclusive of re-examination fees, which have to be paid in case the candidate fails to pass his examination.

The Conjoint Colleges also confer a diploma in Public Health, of which information will be found on page 276.

ROYAL COLLEGE OF PHYSICIANS.

This College issues a Licence in Medicine and a Licence in Midwifery to Registered Medical Practitioners.

The subjects of examination for the former qualification are:—Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene and Therapeutics.

The candidate for the Licence in Midwifery must produce certificates of having attended a course of lectures on Midwifery, and of having attended practical Midwifery and Diseases of Women for six months, at a lying-in Hospital or Maternity recognised by the College; or, where such Hospital attendance cannot have been obtained during any period of the candidate's course of study, of having been engaged in practical Midwifery under the supervision of a Registered Practitioner holding a public Medical appointment, the certificate in either case to state that at least twenty labour cases have been actually attended. A Registered Medical Practitioner of five years' standing is exempted from the examination by printed questions.

Fees.—Fee for the Licence to Practise Medicine,

£15 15s. Fee for the Licence to Practise Midwifery, £3 3s.

Membership.—The Examinations for Membership are held in January, April, July, and October.

ROYAL COLLEGE OF SURGEONS.

This College grants a licence in Surgery to registered medical practitioners. Candidates who hold registrable surgical diplomas, including the licence of the Apothecaries' Society of London, granted since October, 1886, are admitted to examination without further evidence of study, but candidates who hold medical qualifications only, including the L.S.A. granted before October, 1886, will be required to produce certificates of two courses of lectures in anatomy and dissections, one course of practical histology, one course of lectures in surgery, and one course of operative surgery.

Candidates are examined in surgery, clinical and operative; surgical appliances; and ophthalmic surgery. The fee is £26 5s. The fee for a special examination is £31 10s.

A diploma in Midwifery is also granted after examination to registered medical practitioners. Candidates must produce evidence of (a) attendance on a course of lectures on midwifery and diseases of women and children in a recognised school; (b) attendance or six months' practice at a recognised lying-in hospital or recognised dispensary for lying-in women and children; and (c) of having conducted at least thirty labour cases. The fee for the examination is £15 15s.

Fellowship.—Candidates for the Fellowship of the College must enter their names with the Registrar at least a month before the date of examination, in order that the Council may decide whether to approve of the application. Examinations are held the third Mondays in February, May, and November. If the application is approved, the candidate will be admitted to the next sessional examination or to a special examination (except during the months of August and September) if granted by the Council. Candidates are divided into two grades:—

Grade 1.—Licentiates or graduates in surgery of less than ten years' standing.

Grade 2.—Licentiates or graduates in surgery of more than ten years' standing.

Candidates in Grade 1 must pass two examinations—Primary (in anatomy and physiology) and Final (in surgery). Candidates in Grade 2 need pass but one examination in surgery, surgical anatomy, and surgical pathology.

Fees.—Grade 1.—For Licentiates of College; Primary examination, £15 15s.; Final examination, £10 10s. Licentiates in Surgery of other licensing bodies: Primary examination, £26 5s.; Final examination, £15 15s. Students of the College: Primary examination, £5 5s.; Final examination, £21. Students of other licensing bodies: Primary examination, £10 10s.; Final examination, £31 10s.

Grade 2.—Licentiates of the College, £26 5s.; Licentiates in Surgery of other licensing bodies, £42.

APOTHECARIES' HALL OF IRELAND.

The Licence of this Hall is granted to students who present certificates of having fully completed the course of study as laid down in the curriculum. The diploma of the Apothecaries' Hall of Ireland entitles the holder to be registered as a practitioner in medicine, surgery, and midwifery, and he also possesses the privileges of an apothecary.

There are four professional examinations, the total fees for which amount to 21 guineas. Women are eligible for the diploma.

Candidates already on the "Register" will receive the diploma of the Hall upon passing an examination in the subjects which are not covered by their previous qualification, and on paying a fee of ten guineas; if medicine or surgery is required, two guineas extra will be charged.

The fees payable for each examination are as follows: First Professional, £5 5s.; Second, £5 5s.; Third, £5 5s.; Final Examination, £6 6s.

A candidate is allowed for each professional examination which he has completed at any other licensing body, except the Final. If he has passed only in some of the subjects in a given examination, he has to pay the whole of the fee for that examination.

The fees for re-examination are: For each subject, £1 1s., excepting in the subjects of chemistry, pharmacy, surgery, medicine, second anatomy, and ophthalmology, the fees for which are £2 2s. each.

The fee for the Third and Final, or Final alone, is £15 15s., when the other examinations have been taken elsewhere.

All examination fees are to be lodged in the Sackville Street Branch of the Royal Bank of Ireland to the credit of the Examination Committee.

Applications and schedules, together with bank receipt for the fee, must be lodged with the Registrar, Apothecaries' Hall, 40, Mary Street, Dublin, at least fourteen clear days before the day of examination.

Candidates who desire to obtain the Letters Testimonial of the Apothecaries' Hall of Ireland, must, before proceeding to the Final Examination, produce evidence of having been registered as medical students for fifty-seven months; also of having attended courses of instruction as follows:

One course each (winter course of six months) of the following: Anatomy (lecture), chemistry (theoretical), midwifery, practice of medicine, physiology or institutes of medicine and surgery. Dissections, two courses of six months each.

Courses of three months.—Materia medica, medical jurisprudence, chemistry (practical), practical physiology and histology, operative surgery, physics, clinical ophthalmology, biology, clinical instruction in mental disease, pathology, vaccination.

Medico-Chirurgical Hospital, twenty-seven months to be distributed over the last four years of his study. The candidate may substitute for nine months in this, hospital attendance for six months as a resident pupil.

Three months' study of fever.

Six months' practical midwifery and diseases of women.

Three months' practical pharmacy in a recognised clinical hospital or a recognised school of pharmacy, or a year in the compounding department of a licentiate apothecary or a pharmaceutical chemist.

Each candidate before receiving his diploma must produce evidence that he has attained the age of 21.

Each candidate must produce evidence of having before entering on medical studies passed a preliminary examination in general education recognised by the General Medical Council, and of having been registered by that Council as a student in medicine. Certificates of medical study will not be recognised if the commencement of the course to which the certificate refers dates more than fifteen days prior to such registration, except in the subjects of physics and biology. This registration is not undertaken by the Hall.

The details of the course of education required and syllabus of the examinations will be supplied on application to the Registrar, at 40, Mary Street, Dublin.

LICENCE IN DENTAL SURGERY.

There is probably no specialty in surgery which gives as great a number of its practitioners a living and the prospect of an income as dentistry. A young man who has got his diploma and knows something of his business, and is willing to attend to it, seldom fails to get a substantial foothold in Ireland in a few years. The University of Dublin grants both a Degree and a Licence in dental surgery. To obtain the former, candidates must have taken a degree in arts; the licence is obtainable by all duly qualified persons who have passed the Public Entrance Examination of Trinity College, Dublin. The Royal College of Surgeons in Ireland grants a Licence in Dentistry.

Course of Study for the Licence in Dentistry.—Candidates are required to pass three examinations, viz. :—Preliminary (in General Education), Primary Dental, and Final Dental.

All information concerning this licence may be obtained from the Registrar of the College. The Primary Dental Examinations commence on the second Monday in the months of February, May, and November. The subjects of examinations include physics, chemistry (including metallurgy), anatomy, physiology and histology, and surgery. The fees for the primary Dental Examination amount to £10 10s; and for re-examination, if rejected, £5 5s. The Final Dental Examinations commence on the Thursdays immediately following the Primary Dental Examinations. Candidates are examined in dental surgery, theoretical (including dental pathology), clinical, and operative; and in dental mechanics, theoretical, clinical, and practical (including the metallurgy of the workshop). Candidates must pass in all the subjects at the same time.

The fees for the Final Dental Examination in the case of candidates holding the L.R.C.S.I., or students who have passed the Primary Dental or Third Professional Examination of the College, £10 10s.; re-examination, £5 5s. The fees for Final Examination of all other candidates, £26 5s., and for re-examination, £10 10s. The extra fee for Special Examination, £5 5s. A rejected candidate will not be again admitted to examination until after a period of three months.

THE DIPLOMA IN PUBLIC HEALTH.

This diploma is granted by Dublin University, the Royal University, and the conjoint Royal Colleges. Every candidate must be a registered medical practitioner. The examination is in:—(1) Chemistry (including chemical physics). (2) Engineering and architecture. (3) Sanitary law and vital statistics. (4) Hygiene. (5) Bacteriology. (6) Meteorology. The General Medical Council recommend that all candidates shall have studied in a special bacteriological laboratory, also for six months as pupil of a working medical officer of health, described, for Ireland, as "the medical officer of health of a county or of one or more sanitary districts having a population of not less than 30,000; or a medical officer of health who is a teacher in Public Health of a recognised medical school."

In addition to taking the prescribed course a candidate for the D.P.H. of the University of Dublin must be a Doctor in Medicine or a graduate in Medicine, Surgery, and Midwifery of Dublin, Oxford, or Cambridge, and his name must have been on the "Medical Register" for at least twelve months before the examination. The Royal University only confers its diploma on its own graduates.

THE DIPLOMA IN PSYCHOLOGICAL MEDICINE.

The Royal University of Ireland grants a diploma for proficiency in the treatment of mental diseases under the following conditions:—

The diploma is conferred only on graduates in medicine of the University. Candidates must give notice, in writing, to the secretaries of their intention to present themselves, and must pay the prescribed fee of £2 at least one month previous to the examination. Candidates who satisfy the examiners will be required to pay a further fee of £3 before the diploma is conferred. The subjects for this examination are those required by the Hutchinson Stewart Scholarship for proficiency in the treatment of mental diseases.

THE IRISH MEDICAL SCHOOLS.

The Irish Medical Schools are as follows:—

THE SCHOOL OF PHYSIC OF DUBLIN UNIVERSITY.—This school is formed by an amalgamation of the School of Trinity College and of the College of Physicians.

Every student of the school must be matriculated by the Senior Lecturer, for which a fee of 5s. is payable, but he need not attend any of the Arts course unless he desires to obtain a University licence or degree in medicine, surgery, and midwifery. No student is permitted to matriculate unless he has passed the entrance examinations of the University, of the Royal University, of the College of Surgeons, or some other examination recognised by the General Medical Council,

Two medical scholarships are given annually at the School of Physic, value £20 per annum, tenable for two years, the examinations for which are held each year in June; one scholarship is given in anatomy and institutes of medicine; the other in zoology, chemistry, botany, and experimental physics.

A prize of £100 is awarded by the Board to the successful candidate at a special examination in alternate years in medicine or in surgery, provided that the merit be deemed sufficient. The successful candidate is required to spend three months in the study of medicine or surgery, as the case may be, in Berlin, Paris, or Vienna. Before he can obtain the first instalment of £50 he must satisfy the Senior Lecturer that he possesses sufficient knowledge of a Continental language to derive full benefit from the prize. The examination is held in June, and is open to students who have passed the Final Examination in Medicine or in Surgery, as the case may be, within two years of the examination.

In order to obtain the second sum of £50 the prizeman must have furnished to the Regius Professor his formal report on the hospitals attended by him within two years from the time of obtaining the prize.

Class prizes are given at the end of the session of between £5 and £10 in value.

The John Mallet Purser Medal, founded by Prof. Purser's past pupils, is awarded annually to the student who, at the ordinary June "Half M.B." Examination in Anatomy and Institutes of Medicine, shall obtain highest marks in Physiology and Histology, provided that he passes the examination in full.

Fitz-Patrick Scholarship.—This scholarship consists of the interest on £1,000. It will be awarded annually to the student who obtains the highest aggregate marks at the five sections of the Final Examinations, provided that he has completed his medical course in the prescribed period of five years.

THE ROYAL COLLEGE OF SURGEONS IN IRELAND. SCHOOLS OF SURGERY.—These schools are attached by Charter to the Royal College of Surgeons, and have existed as a department of the College for over a century. They are carried on within the College buildings, and are specially subject to the supervision and control of the Council, who are empowered to appoint and remove the professors, and to regulate the methods of teaching pursued. The buildings have been reconstructed, the capacity of the dissecting room nearly trebled, and special pathological, bacteriological, public health, chemical, and pharmaceutical laboratories fitted with the most approved appliances, in order that students may have the advantage of the most modern methods of instruction. A refreshment room is now open, where students can have luncheon. There are special rooms set apart for lady students. The entire building is heated by hot-water pipes, and lighted throughout by the electric light.

All the lectures and courses of practical instruction may be attended by medical students who are otherwise unconnected with the College.

The diplomas of the College are open to students of either sex. Separate rooms have been provided, and careful provision made for the instruction and comfort of women students.

Prizes.—The Barker Prize, £31 10s.; the Carmichael Scholarship, £15; the Mayne Scholarship, £8. The Gold and Silver Medals in Surgery and the Stoney Memorial Gold Medal in Anatomy.

Class Prizes of £2 and £1, accompanied by medals if sufficient merit is shown, will also be given in each subject. Prospectus and Student's Guide can be obtained on written application to the Registrar, Royal College of Surgeons, Dublin.

THE CATHOLIC UNIVERSITY SCHOOL is situated in Cecilia Street, Dame Street. It prepares students for all medical examinations, particularly those of the Irish Colleges of Physicians and Surgeons, and the Royal University of Ireland. The school has recently been rebuilt and refitted, its working space having thereby been nearly doubled, and several new laboratories, including those for the study of bacteriology and

public health, have been added. The institution was also been recently chartered, under the Educational Endowment (Ireland) Act, and it is now controlled by a Board of Governors. The total fees for school and hospital courses is £160, payable as the courses are taken out.

The following Exhibitions are awarded annually :— Two first year's, value £12 10s. each ; two second year's, value £10 each ; one third year's Royal Exhibition of £12 10s. ; one final Conjoint Colleges Exhibition of £12 10s. ; two large gold medals, besides several other class medals.

A Guide for Medical Students, which gives all the information required by parents, and by students who desire to join the medical profession, may be obtained free on application to the Registrar.

THE QUEEN'S COLLEGES—BELFAST, CORK, AND GALWAY.

These three important academic institutions were the special schools of the Queen's University. They have ceased to have any direct relation to a central examining body, but educate students for all colleges and degrees, and are maintained, as hitherto, by a handsome Government grant. The same curriculum as that formerly adopted is continued, and the various exhibitions and scholarships are still available. Each college has the disposal of about £1,500 per annum in scholarships and prizes. The curriculum is generally well adapted for preparation for the Royal University examination. The colleges are well adapted for high-class technical education, having lecture rooms provided with every appliance necessary in the modern training of a medical student. The colleges are completely equipped with students' reading rooms and lending libraries and refreshment rooms, and with all adjuncts to collegiate life, such as literary societies and athletic organisations. The expense of living in the collegiate towns is quite moderate. The course of lectures in the winter session must be diligently attended, no student obtaining a certificate who has not put in three-fourths of a course. The scholarship examinations are held in October.

QUEEN'S COLLEGE, BELFAST.

The total cost of the medical curriculum of the Royal University of Ireland, including examination fees and perpetual fee for the Royal Hospital, but not including fees for the special hospitals, is about £95. If the Conjoint Examination of the Royal Colleges is taken the expense is almost the same.

Clinical instruction is given at the Royal Victoria Hospital. The Union Hospital, the Maternity Hospital, the Ulster Hospital for Women and Children, the Hospital for Sick Children, the Ophthalmic Hospital, the Ulster Eye, Ear, and Throat Hospital, and the District Lunatic Asylum are also open to students.

Prizes.—(1) Ten medical scholarships each year, value £20 each ; (2) two Dunville studentships (one each alternate year), value £150 each ; (3) one Andrews studentship each alternate year, value £140 ; (4) numerous sessional prizes.

During the summer session special classes are formed in bacteriology and clinical pathology, and during the winter facilities are afforded to medical men to work at these subjects in the pathological laboratories. From time to time lectures and demonstrations are given in the anatomical department on the Advanced Anatomy of the Nervous System, or some other department of applied anatomy.

A pamphlet containing full information can be had on application to the Registrar, Queen's College, Belfast.

QUEEN'S COLLEGE, CORK.

The arrangements in the Faculty of Medicine are made chiefly with reference to the requirements of the Royal University of Ireland, but students proceeding for the examinations of the Conjoint Boards of England, Scotland, or Ireland, the Society of Apothecaries of London, or the Apothecaries Hall of Ireland, can arrange the course of lectures which they attend, and the order in which they attend them, to meet the re-

quirements of those bodies. Certificates of attendance in the college are also accepted by the University of Cambridge. The total fees for the college lectures and Hospital attendances required by the Royal University of Ireland is about £85.

Clinical instruction is given at the North and South Infirmarys. Students can also attend the Mercy Hospital, the Cork Union Hospital, the County and City of Cork Lying-in Hospital, the Maternity, the Hospital for Diseases of Women and Children, the Fever Hospital, the Ophthalmic and Aural Hospital, and the Eglinton Lunatic Asylum. The winter session commences on October 27th, and ends at the end of April. The courses of the summer session are delivered in the months of April, May, and June.

Scholarships and Prizes.—Eight medical scholarships, two in each of the first four years, of the value of £25 each, and in the fifth year the Blaney Scholarship of the value of about £32, and a Senior Exhibition, value £30. Three Exhibitions, one in practical medicine, one in practical surgery, and one in practical midwifery, each of the value of £15. Book prizes at the sessional examinations.

Further information can be obtained in the College Regulations, or on application to the Registrar, Queen's College, Cork.

QUEEN'S COLLEGE, GALWAY.

Clinical teaching is carried on in the Galway Hospital, established as a Public General Hospital (in the place of the County Galway Infirmary) by Act of Parliament (1892). The Galway Fever Hospital is also open to students. The medical lectures are recognised by the Royal University of Ireland and the various Licensing Bodies in the United Kingdom.

Prizes.—There are eight Junior Scholarships in Medicine of the annual value of £25 each. Two are tenable by matriculated students of the first, second, third, and fourth years. The Council has power to award exhibitions for distinguished answering. Sessional prizes are offered in each subject. A Senior Scholarship in Anatomy, value £40, the holder of which is usually appointed Demonstrator, is offered annually for competition, tenable for one year by a student who shall have attended the Medical School of the College for at least two sessions, and shall have obtained a Degree in Arts or Medicine, or a Diploma in Medicine, from a Licensing Body. Scholarship examinations are held at the commencement, and those for Sessional Prizes at the close, of each session.

THE PHARMACEUTICAL SOCIETY OF IRELAND.

The Pharmaceutical Society of Ireland issue two qualifications and a certificate. The qualification of Registered Druggist ; the qualification of Pharmaceutical Chemist ; and the certificate of competency as Assistant to a Pharmaceutical Chemist.

Registered Druggist.—This qualification entitles the holder to keep open shop for the selling, retailing, and mixing of poisons. In order to obtain it, a person must now have served an apprenticeship or assistantship of four years to an apothecary, pharmaceutical chemist, or to a person who was, or would have been entitled to become, a registered chemist and druggist or a registered druggist, and be 21 years of age. He shall be examined with respect to his knowledge of English orthography and composition, arithmetic, and the weights and measures of the British Pharmacopoeia, the appearance and properties of the various drugs and chemicals in general use, and as to the provisions of the Poisons Act. The fee is four guineas.

Examinations in Dublin (also in Belfast and Cork or other place if 12 candidates offer) on the second Tuesday of January, April, July, and October.

Pharmaceutical Chemist.—The qualification of a pharmaceutical chemist in Ireland confers greater privileges than is the case in England.

The subjects of examination are divided between the "Preliminary" and the "Licence."

The Preliminary examination is held on the first

Thursday and following day of January, April, July, and October.

The fee is £2 2s. for the first attempt, and 10s. 6d. for each subsequent examination. Further particulars with reference to the subjects for examination may be obtained from the Registrar. The British Society's examination is accepted in lieu of this, as well as those recognised by the General Medical Council as a preliminary to medical studies.

Pharmaceutical Licence Examination.—This examination confers the title of Pharmaceutical Chemist and the right to compound medical prescriptions. Candidates must be 21 years of age, and must have passed the Preliminary at least a year previously. They must, unless having passed the Preliminary previous to 1884, produce certificates of having served four years as assistant or apprentice to an apothecary or pharmaceutical chemist or four years to a druggist, two years to an apothecary or pharmaceutical chemist, also a certificate of having attended a course of practical chemistry of not less than three months' duration, and of having actually worked at the bench for 100 hours during the said course at a recognised school; and also a course of botany and *materia medica*. The fee for examination is five guineas, and for re-examination a guinea and a half. Examinations are held in Dublin on the second Wednesday and following day of January, April, July, and October.

Assistant to a Pharmaceutical Chemist.—The examination for the certificate of competency as an assistant may be described, in brief, as the same as that for the Licence, minus the examination in chemistry and botany, with the fee reduced to one guinea (half a guinea on the second and subsequent attempts). The Preliminary examination must be passed as for the Licence, and the usual 14 days' notice must be given. Candidates must have been engaged in practical pharmacy for four years.

Examinations are held on the second Mondays of February, May, August, and November, or on such days as the Council may direct.

DEPARTMENT OF AGRICULTURE AND TECHNICAL INSTRUCTION FOR IRELAND.

ROYAL COLLEGE OF SCIENCE FOR IRELAND. SESSION 1905—1906.

This College, situate in St. Stephen's Green, Dublin, supplies a complete course of instruction in science applicable to the industrial arts, especially those which may be cast broadly under the heads of agriculture, chemical manufactures, engineering, physics, and natural science. A diploma of Associate of the College is granted at the end of the three years' course. Non-associate students may join for any course required. There are several entrance scholarships, (a) in agriculture, and (b) in science and technology, tenable for three years, of the value of £50 each yearly, with free tuition. There are four Royal scholarships of the value of £50 each yearly, with free education, tenable for two years. Two are competed for by the first year associate students at the end of each session. All the laboratories and drawing schools are open daily for practical instruction. The Session commences on Tuesday, October 3rd.

The courses of chemistry, physics, botany, geology, and mineralogy and zoology are recognised by the Royal University of Ireland, and certificates of attendance are granted to medical and other students attending these courses, as also the courses of the chemical, physical, zoological, botanical, and geological laboratories.

The Entrance and Science Scholarship Examinations are held about the first week in July, and the Examinations for Agricultural Scholarships in the second week in September.

THE DUBLIN HOSPITALS.

THE clinical hospitals in Dublin are ten in number, exclusive of three lying-in hospitals. There are also two children's hospitals, an orthopædic hospital, a fever hospital, an ophthalmic hospital with two centres, a

dental hospital, and other special institutions. Some of the clinical hospitals, though they have no actual or official connection with any school, are in close affinity with certain teaching bodies; while others, again, are without any special connection with any school. While, however, such affiliation of a school or hospital may exist, it should be remembered that the Dublin schools and hospitals are open to all comers, and the student is competent to attend any hospital or any school he wishes, and to change his place of instruction from year to year as he may see fit.

The Irish Licensing Bodies require attendance on hospitals for twenty-seven months, *i.e.*, three winter sessions of six months and three summers of three months, with the five years of study. The fee at all general hospitals is £8 8s. in winter, and for the summer £6 6s., or £12 12s. for the entire session of nine months if taken together.

GENERAL HOSPITALS.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.—The accommodation at these hospitals is as follows:—Hardwicke Hospital, 120 beds; Whitworth Hospital, 82 beds; Richmond Hospital, 110 beds—total, 312 beds. These hospitals are visited each morning at nine o'clock by the physicians and surgeons, and, in addition to the usual bedside instruction, clinical lectures are delivered on the most important cases. Instruction is also given on various special branches of medicine and surgery. The Truss Establishment, for the distribution of trusses to the ruptured poor of Ireland, is connected with these hospitals. There are very large ophthalmic, aural, throat, and gynaecological dispensaries, and instruction in these important subjects is given. Eight resident clinical clerks are appointed each quarter, and provided with furnished apartments, fuel, &c. The appointments are open not only to advanced students, but also to those who are qualified in medicine and surgery. A house surgeon for the Richmond Hospital and a house physician for the Whitworth and Hardwicke Hospitals are elected every six months, and receive a salary. The Richmond Lunatic Asylum, containing 1,600 beds, adjoins these hospitals.

MEATH HOSPITAL AND CO. DUBLIN INFIRMARY.—This hospital was founded in 1753, and now contains 160 beds available for clinical teaching. A new building for the isolated treatment of fevers, containing 40 beds, has recently been added. The certificates of this hospital are recognised by all the Universities and licensing bodies of the United Kingdom. Medical and surgical resident pupils and clinical clerks and dressers are appointed every three months, and a house surgeon is elected annually. A prospectus giving the complete arrangements for medical and surgical classes for the coming session may be obtained from the Secretary of the Medical Board, Mr. William Taylor, F.R.C.S., 32, Harcourt Street, Dublin.

THE ADELAIDE MEDICAL AND SURGICAL HOSPITALS occupy a central position within a few minutes' walk of the College of Surgeons and Trinity College. From October 1st, the physicians and surgeons visit the wards and give instruction at the bedside at the advertised hours. There is a large detached fever hospital, and also wards for infants and children. Operations are performed, except in cases of urgency, at 10 a.m. on Tuesday, Thursday, and Saturday. Special hours are devoted to clinical instruction in the diseases peculiar to women, and students are individually instructed in the use of the stethoscope, ophthalmoscope, laryngoscope, and microscope; also special instruction is given on practical pathology and X-ray photography. A House Surgeon is elected annually and four resident pupils half-yearly. Prize examinations, including examinations for the Hudson Scholarship, £30 and a gold medal, and a senior prize of £10 and a silver medal, in addition to surgical and medical prizes, are held at the termination of the session. The large dispensaries afford facilities for the study of eye, ear, throat, and cutaneous diseases, as well as of minor surgery and dentistry. Further particulars from Mr. Heuston, F.R.C.S.I., 15, St. Stephen's Green North.

THE ROYAL CITY OF DUBLIN HOSPITAL.—This hospital has recently been enlarged and improved to a very considerable extent. A special course of instruction is given on ophthalmic and aural disease. There are special wards for the treatment of diseases of the eye, of children, and of women, and practical instruction is given on diseases peculiar to women; there is also a separate building for infectious diseases. Clinical clerks to the physicians and dressers to the surgeons are appointed from the most deserving of the class. A new operation theatre, sterilising room, and anæsthetic room have been constructed in accordance with the most modern surgical requirements. A Röntgen-ray and light treatment of lupus department has recently been added. A resident medical officer is elected annually, and resident medical and surgical pupils are appointed from among the past and present students of the hospital. Operations are performed on Tuesdays, Thursdays, and Saturdays, at 10 a.m. Special classes for first year students. Full particulars can be had on application to Mr. G. Jameson Johnston, M.B., F.R.C.S.I., Hon. Sec. Med. Board.

SIR PATRICK DUN'S HOSPITAL is situated on the south-eastern side of the city, and about half a mile from the University School of Physic. It is officered almost exclusively by the professors and examiners in that school. Formerly all University students were compelled to attend this hospital, which was purely a medical institution, but some years ago the obligation was removed, and the hospital was opened for surgical cases. It is now free to all students. There is a special wing devoted to fever cases, and regular clinical instruction is given by the members of the medical staff throughout the winter and summer sessions. Special classes for students commencing their hospital studies will be held in these departments during the months of October, November, and December. They will embrace the elements of medicine and surgery, including note-taking. Opportunities are also afforded to students for examining cases of throat, ear, and eye diseases, as well as for performing minor surgical operations and bandaging. In the X-ray Department opportunities are given the members of the hospital class of seeing the various applications of the X-rays to the diagnosis and treatment of injury and disease.

MATER MISERICORDIÆ HOSPITAL.—This hospital, containing 335 beds, is open at all hours for the reception of accidents and urgent cases. Fifty beds are specially reserved for the reception of patients suffering from fever and other contagious diseases. A course of lectures and instruction on fever will be given during the winter and summer sessions. A certificate of attendance upon this course to meet the requirements of the various licensing bodies may be obtained. Opportunities are afforded for the study of the diseases of women in the wards under the care of the obstetric physician, and at the dispensary, held on Tuesdays and Saturdays. Lectures on clinical gynæcology will be delivered on Saturdays at 11 a.m. Ophthalmic surgery will be taught in the special wards and dispensary. A special course of instruction in pathology and bacteriology, as applied to medicine, will be given. Connected with the hospital are extensive dispensaries, which afford valuable opportunities for the study of general, medical and surgical diseases, accidents, &c. Leonard Prizes: One gold and one silver medal will be offered for competition annually in the subject of medicine, and one gold and one silver medal in the subject of surgery. Junior Leonard Prizes: Two prizes of the value of £3 and two prizes of the value of £2 will be offered for competition in medicine and surgery respectively.

MERCER'S HOSPITAL.—This hospital, founded in 1707, is situated in the centre of Dublin, in the immediate vicinity of the Schools of Surgery of the Royal College of Surgeons, the Catholic University School of Medicine, and Trinity College. It contains 120 beds for medical and surgical cases, and arrangements have been made with the medical officers of Cork Street Fever Hospital whereby all students of this hospital are entitled to attend the clinical

instruction of that institution and become eligible for the posts of resident pupil, &c. There is a large out-patient department, and a special department for diseases peculiar to women. There are also special wards for the treatment and study of children's diseases. During the past few years the hospital has undergone extensive alterations in order to bring it up to modern requirements. A house surgeon is appointed annually. Five resident pupils are appointed, each for six months, and clinical clerks and dressers are appointed monthly from among the most deserving members of the class. The certificates of this hospital are recognised by all the licensing bodies. For further particulars apply to Mr. R. Charles B. Maunsell, M.B., F.R.C.S., 32 Lower Baggot Street, Dublin.

ST. VINCENT'S HOSPITAL was established in 1834. It has 160 beds, and in connection with it there is a largely-attended dispensary, a convalescent home, and a nurses' institute. In addition to the ordinary clinical instruction, systematic courses of lectures are given in each department of medicine and surgery, and are illustrated by cases in the hospitals. The resident officers consist of a house surgeon, a house physician, and four resident pupils. Three clinical lectures are delivered daily in the wards, illustrated by selected cases, and beginning at 9 a.m. Two gold medals and other valuable prizes and certificates of merit are awarded at the end of each session. A prospectus can be had from Surgeon Fagan, 31, North Frederick Street.

DR. STEEVENS' HOSPITAL, situated at Kingsbridge, is one of the oldest and largest of the clinical hospitals in Dublin, and contains over 200 beds. Recently, a very fine Nurses' Home has been added to the institution, with accommodation for over seventy nurses. And a new and thoroughly equipped dispensary and out-patient department has been completed and opened to patients. There is accommodation for twelve resident pupils—four medical, six surgical, and two in the special departments, each of whom is supplied with a separate room. All information with regard to these appointments can be had from the Resident Medical Officer at the hospital. Licensing bodies recognise six months' residence as equivalent to a year's ordinary attendance at hospital. The manufactories and railway works in the neighbourhood supply this hospital with large numbers of accidents and other cases, while the special ward for venereal diseases affords exceptional opportunities for the study of this important subject.

JERVIS STREET HOSPITAL is the oldest established in Dublin. The new hospital was completed in 1896, since which time it has been open for the reception of patients. In addition to large medical and surgical dispensaries, the out-patient department includes special departments for the treatment of diseases of the skin, eye, ear, and throat, and diseases peculiar to women. Two resident surgeons are appointed annually. Clinical clerks and surgeons' dressers are selected from among the most attentive of the advanced students without the payment of any additional fee. Twelve interns are appointed annually, and are provided with apartments, &c., free of expense. Special certificates are given to resident pupils and dressers who have performed their respective duties to the satisfaction of the physicians and surgeons. Gold and silver medals are given after examinations held at the close of the summer session.

Students of Jervis Street Hospital are entitled to attend free of charge the Children's Hospital, Temple Street, which contains 100 beds, and where special lectures are given on Diseases of Infancy and Childhood, and on Orthopædic Surgery and appliances.

SPECIAL HOSPITALS.

The special hospitals of Dublin are the Rotunda, the Coombe, and the National Lying-in-Hospitals, Cork Street Fever Hospital, the Royal Victoria Eye and Ear Hospital (amalgamation of St. Mark's Ophthalmic Hospital and the National Eye and Ear Hospital), the

Dental Hospital, the Throat Hospital, the Orthopædic Hospital, the Children's Hospitals in Harcourt Street and in Temple Street, and the City Hospital for Diseases of the Skin.

THE ROTUNDA HOSPITAL.—This institution is the largest, the longest established, and the most famous gynaecological as well as maternity hospital in the British Empire. The work performed by it is about three times greater than that of any other hospital of its kind in Ireland. The number of patients admitted to the hospital, and also attended in the extern maternity has increased enormously within recent years. The routine daily work comprises the attendance of lectures on midwifery and gynaecology; practice in abdominal palpation; personal conduction of parturition both in the extern and the intern maternities; cystoscopic examinations, as well as attendance at the operation work of the hospital. The hospital affords exceptional advantages to qualified men who take out a three months' course during the autumn, winter, and spring months, for they (if considered competent) are permitted a certain amount of practical operation work, viz.—forceps, curettings, perineorrhaphy, &c. Students are liable to summary dismissal without refund of fees for gross misconduct, or serious breach of the hospital rules. A special afternoon class in gynaecology is held by the Senior Assistant, £2 2s. per month. The Pathological laboratory under the direction of Dr. Rowlette has become an important feature of the hospital. Students can enter at any time for periods of one month or longer. Certificates of attendance are accepted by all the licensing bodies. The L.M. certificate is obtained by attendance at the hospital for six months, with the subsequent passing of an examination. A special certificate in gynaecology is presented to students whose work meets with the Master's approval. Paid clinical assistants are selected from among those who have obtained the hospital L.M. certificate) by competitive examination, for periods of six months. The residents' quarters have undergone complete renovation and now afford comfortable accommodation. The grounds of the hospital contain asphalt and grass courts for lawn tennis and croquet. There is also a full-size billiard table.

Fees for Pupils.—*Intern:*—One month, £6 6s.; two months, £9 9s.; three months, £12 12s.; six months, £21; single months other than the first, £4 4s.; board and lodging in the house per week, £1 5s. Night students (not resident in house), £6 6s. for first three months; £4 4s. for the second three months. For further particulars apply to E. Hastings Tweedy, Master, Rotunda Hospital, Dublin.

COOMBE LYING-IN HOSPITAL.—This hospital consists of two divisions, one of which is devoted to lying-in cases, and the other to the treatment of diseases peculiar to women. The practice of this hospital is one of the largest in Ireland; nearly 18,000 cases are treated annually, either as intern or extern patients. Lectures are delivered, practical instruction is given, and gynaecological operations are performed in the theatres daily. There is a general dispensary held daily, at which instruction is given on the diseases of women and children. There is a special afternoon dispensary held by the Master and his assistants, at which practical instruction in gynaecology is given. This is the largest dispensary of its kind in Dublin. There is no extra charge for attendance at this dispensary. There is accommodation for a number of qualified and unqualified intern pupils, who enjoy exceptional advantages of acquiring a thorough knowledge of this branch of their profession. Lady medical students can reside in the hospital. Clinical assistants are appointed from among the pupils as vacancies occur. Certificates of attendance at this hospital are accepted by all licensing bodies, and the diploma is recognised by the Local Government Board as a full legal midwifery qualification. The residents' quarters have been much enlarged. A billiard table has been erected for the use of students. Extern pupils pay, for full course of six months, £8 8s. Intern pupils pay one month, £4 4s.;

six months, £18 18s. Board and lodging in the hospital, 18s. per week. Lady students' intern pay for one month, £5 5s.; each consecutive month, £4 4s.

*** NATIONAL MATERNITY HOSPITAL.**—This institution, under the mastership of Dr. Barry and Dr. A. Horne, is situated in Holles Street.

SIR PATRICK DUN'S MATERNITY.—This is a branch of Sir P. Dun's Hospital, and is under the management of the King's Professor of Midwifery in Dublin University. The department is at present in process of being reorganised.

CORK STREET FEVER HOSPITAL is the only special fever hospital in Dublin. It is supported mainly by subscriptions, an annual Government grant, and capitation grants for patients. Regular clinical instruction is given during the winter and summer sessions to those who desire a special course in fevers. There are also courses for the Diploma in Public Health. All particulars may be obtained on application to the Medical Superintendent.

THE NATIONAL CHILDREN'S HOSPITAL for the treatment of all non-infectious diseases peculiar to children, with which the Pitt Street Children's Hospital, founded in 1821, was amalgamated, is capable of containing 50 beds for the reception of cases of deformity and all other forms of surgical disease. There is a large general dispensary for extern patients held daily from 10 to 11. Operations are performed on Saturday at 12 o'clock. Practitioners and students can attend on application to Sir Lambert H. Ormsby, F.R.C.S.I.

*** THE CHILDREN'S HOSPITAL, DUBLIN** (under the care of the Sisters of Charity).—This institution is one of the most progressive and up-to-date children's hospitals in the Kingdom, besides being the largest in Ireland. There are 100 beds available for patients; about 1,000 cases are admitted to the wards annually; and about 7,000 or 8,000 seen in the dispensary. During the last year a new operating theatre has been opened. It is fitted and furnished in the best possible fashion for present-day surgery. Special attention is given to orthopædic surgery, and the number of deformities from all parts of Ireland treated and cured in the hospital is rapidly increasing. A special masseuse has been appointed to the hospital to aid in this department. A convalescent home for the institution has recently been acquired at Raheny; twenty beds are available. While situated in the country, it is within very easy reach of the sea, and during the summer the children are brought daily to the sea-side.

The hospital is recognised for clinical instruction in the diseases of children by the R.U.I. and licensing bodies, which require a certificate of instruction in this important branch of medical education. A nursing home is in connection with the institution, and trained nurses are always available for private cases. Senior students or others requiring a post-graduate course at the hospital should apply for full particulars to H. C. Mooney, hon. sec., or to any member of the staff.

THE INCORPORATED ORTHOPÆDIC HOSPITAL, IRELAND.—This hospital was founded in 1876, and contains 80 beds. It is available for every class of deformity available for treatment. Particulars may be obtained from Captain Borthistle, Registrar, at the hospital, or from R. L. Swan, F.R.C.S.I., 32 Stephen's Green.

THE ROYAL VICTORIA EYE AND EAR HOSPITAL, Adelaide Road, Dublin.—This hospital, which was opened in March, 1904, is an amalgamation of St. Mark's Ophthalmic Hospital and the National Eye and Ear Infirmary. The hospital contains 80 beds. Clinical instruction in diseases of the eye and ear, including the use of the ophthalmoscope and operations, is given daily from 10 till 1. Special classes for practical instruction in the use of ophthalmoscope, &c., and for the demonstration of cases, are formed from time to time.

THE INCORPORATED DENTAL HOSPITAL, Lincoln Place.—This handsome hospital, recently erected, is the only special Dental Hospital in Dublin. It is

officer by a very strong staff of the leading dental surgeons of Dublin, and has a large *clientèle* and extensive practice among the Dublin poor. The fees are £15 15s. for the first year's study, and £12 12s. for second, and proportionately smaller fees for shorter periods.

THE CITY HOSPITAL FOR DISEASES OF THE SKIN AND CANCER, Great Brunswick Street.—The first and only one of its kind in the city was the first in Ireland to instal the Finsen treatment. Senior students are admitted free to the practice of this hospital, which has a large daily out-patient attendance. Classes of instruction will be given at regular intervals during the winter and summer sessions in the use of the Finsen light, X-rays, high frequency currents and radium, with demonstrations on (1) the production and use of the Röntgen rays, (2) electric currents, direct and alternating, with description of resistances, rectifiers and transformers; (3) accumulators, their construction, use, and methods in charging; (4) vacuum tube, choice of tube for particular kinds of work. Fluorescent screen, and how to localise foreign bodies.

BELFAST HOSPITALS.

* **HOSPITAL FOR SICK CHILDREN, Queen Street.**—This institution, erected by voluntary donations, and supported by voluntary contributions, was opened for the reception of patients on April 24th, 1879. The hospital consists of a medical ward with twenty-eight beds, and one of a similar size for surgical cases. It is strictly non-sectarian in its principles, and is open to all denominations. Children from birth to the age of 12 years, and not suffering from contagious disease, are admissible as in-patients. A very large extern is conducted in the out-patient department between the hours of 9 and 10 a.m., where children from birth to 14 years are attended to. The convalescent home, which is situated at Newtownbreda, contains thirteen cots, and its situation and equipment render it an admirable adjunct to the after-treatment of the cases admitted to the hospital. During the winter session systematic courses of lectures and demonstrations in the medical and surgical diseases of infancy and childhood are delivered in the wards on Wednesday and Friday of each week at 9 a.m.

* **MATER INFIRMORUM HOSPITAL.**—Established 1883. 160 beds.

THE BELFAST MATERNITY HOSPITAL (INCORPORATED).—Established 1794. 25 beds.—The practice of the Maternity Hospital, the certificate of which is recognised by the Royal University, &c., &c., is open to students. The fee for the session is £2 2s. Resident nurses are also received for training for a period of six months, and a diploma given which is recognised by public bodies. Conditions for such on application to the Matron. During the year 1904, 295 patients were treated in the hospital, and 291 patients at their own homes. Besides this, 278 patients were dealt with in the extern gynæcological department. Clinical lectures and bedside demonstrations are given by members of the staff during both the winter and summer sessions. Students wishing to attend should apply to Dr. H. D. Osborne, 32 Lonsdale Terrace, Belfast, Hon. Secretary to Medical Staff, on or before November 1st and May 1st.

Note.—Hospital was rebuilt during the year, and hence numbers were reduced during removal to the splendidly equipped new hospital in Townsend Street. A Resident Surgeon elected periodically.

OPHTHALMIC INSTITUTION AND EYE AND EAR HOSPITAL, Great Victoria Street, Belfast.—Established 1844. New hospital erected, 1867. New extern department and operation theatre added, 1902. This hospital is situated on the main road between Queen's College and the Royal Victoria Hospital. It contains about 30 beds for intern patients, and a large extern department. The latter is open on Monday, Wednesday and Friday at noon for eye cases, and on Monday and Thursday at noon for ear and throat cases. Special courses of instruction are given during the winter and summer sessions, but students can enter at any time, and can always obtain plenty of practice in

ophthalmoscopic work. Full particulars may be had from Dr. Cecil Shaw, 18 College Square East, Belfast.

ROYAL VICTORIA HOSPITAL.—Established 1791; incorporated by Royal Charter, 1875 and 1898. New hospital opened, September 17th, 1903. 300 beds; Convalescent hospital, 24 beds; Children's Hospital, 33 beds; Consumptive Hospital, 10 beds.

ULSTER EYE, EAR, AND THROAT HOSPITAL.—Established 1871; New hospital opened 1874; 30 beds.
